Special Considerations When Undertaking Studies Involving Human Milk

Studies involving human milk have a number of special considerations that need to be taken into account. Because human subjects and tissues are involved, the following areas should be addressed when planning to conduct any survey of human milk.

Ethics

Any study that involves human subjects must be carefully planned and approved by an authorized ethics review committee to be certain that the rights of the individuals participating in the study are protected. Mothers donating samples of their milk should be informed of the nature and purpose of the survey and asked to sign an informed consent form for this purpose. It is the responsibility of the lead researcher to ensure that the protocol for the study meets all national ethical and informed consent requirements. This includes adequate safeguards to ensure the confidentiality of any information regarding the donors and especially the results, which should only be identified by code. Based on national requirements, donors may be provided with the results of their samples. If such information is provided, considerable judgment must be used in characterizing various levels of POPs. The provision of individual results should always be accompanied by an explanation giving the range of other results and a short interpretation of the health significance of the values.

General Principles

Because studies will often involve primiparae mothers, the practicality, feasibility, and sustainability of sample collection from the donor's perspective should be given the highest priority. In addition, the following principles should be considered during development of the protocol and implementation of the study:

- Breastfeeding should be protected, promoted, and supported.
- The health benefits of breastfeeding for both mother and baby should be clearly and consistently communicated.
- Sampling of milk should not be an undue burden on the mother nor should it compromise the nutritional status of the infant.
- Ethical review, including prior informed consent, should be respected.
- Safeguarding of confidential information should be assured.

- Analytical quality assurance should be independently confirmed.

Criteria for the Selection of Donors

The criteria for selection of donors need to be designed to reduce the variability among the individual samples due to factors that are known to influence the levels of environmental chemicals in human milk. When the intention is to assess trends in levels over time, the reduction in variability is particularly important. However, overly stringent criteria in the selection of donors may give rise to an insufficient number of qualified donors. Consideration of available statistics on primiparae mothers and experiences from other studies involving mothers may be of assistance when developing selection criteria for donors. The following criteria were developed for a study of POPs and may be appropriate for other studies of chemicals that bioaccumulate in humans:

- Mother should be primiparae.
- Mother should be under 30 years of age.
- Both mother and child should be apparently healthy, including normal pregnancy.
- Mother should be breastfeeding one child only (i.e., no twins).
- Mother should have resided in the area for at least the previous 10 years.
- Mother should not reside in local areas where emissions of POPs are known to occur.
- Mothers should be available for sample collection within 3–8 weeks of delivery.

The location of residence of the donor, usually urban or rural, may also be associated with different exposure levels. Living in highly polluted areas, such as in the vicinity of incinerators, pulp and paper industries, and metal industries, is known to influence exposure to some chemicals. Persons with markedly different exposures should not be included in the survey to avoid skewing the results. Factors known to have such effects should be included in the protocol as exclusion criteria.

Collection of Samples

Once breastfeeding is well established, sampling can be carried out between 3 and 8 weeks (21 days to 2 months) after delivery. Donors should receive verbal and written information concerning the survey. The procedures of the survey should be explained, particularly the rights of the donor to withdraw from the survey without prejudice. Following this, the donor should be requested to give their written consent on a standard informed consent form. The sample can then be collected.

Preferably mothers should provide the sample at a local place of contact where collection can be supervised. At least 50 ml of milk in total should be collected by hand expression after a feeding or while the infant is nursing on the other breast, to take advantage of the let-down reflex of the mother. Depending on the wishes of the mother and local customs, a human milk pump to facilitate expression can be provided. Alternatively, the mother may collect the sample at home, in which case manual expression is preferred. If so, she should be given detailed instructions for taking, storing, and transporting of milk samples. Mothers should also be given a clean glass jar with a protected screw cap to collect and store the milk sample. Sample collection jars should be labeled with the donor's individual identification code and not the name of the mother. Milk samples may be stored in the refrigerator at approximately 4 °C for a maximum of 72 h, or for longer times in the freezer at −20 °C.

Biosafety

One of the criteria for selecting women as potential donors is that both the mother and infant should be apparently healthy following a normal pregnancy. The reasons for this criterion are to avoid extra demands on a mother who is already experiencing difficulties and to minimize results that may be caused by medical conditions. For POPs, a sudden loss of weight may mobilize fat stores and increase the levels of POPs in the milk. Consequently, donors with previously diagnosed clinical hepatitis, malaria, acquired immunodeficiency syndrome, and other such diseases should be excluded from the study. In many countries, pregnant women are screened for a number of infectious diseases so that their health status can be evaluated.

In countries which have established human immunodeficiency virus (HIV) screening of pregnant women, the National Coordinator should decide whether HIV-positive donors should be excluded from the study. In this regard, potential weight loss of donors could be an issue as well as the biosafety of the samples. In some countries, discrimination based on HIV status is not allowed legally and in certain countries, a person's HIV status is considered confidential. Although the infectivity of human milk from HIV-positive mothers is considered low when ingested by infants, for the purpose of this study, such milk should be considered infectious unless it is decontaminated. Therefore, any milk sample known or suspected to be contaminated with HIV should be decontaminated by heating at 62.5 °C for 30 min. Such treatment does not alter the levels of POPs in the sample. Similarly for countries with HIV morbidity and no HIV screening, human milk samples should be considered contaminated and heat-treated as above. Staff working with such samples should be suitably trained and provided with personal protective equipment.

Number of Samples

To get statistically reliable data, a minimum of 50 individual samples was recommended for each country. To determine the feasibility of this number of samples, information on the number of infants born to primiparae mothers should be available from the health statistics databases and other records. However, some flexibility may be necessary for countries with small populations and/or low birth rates. If this is a problem, extending the sample collection period should be considered as the first option to increase the number of available donors. In some cases, reducing the number of

donors may be unavoidable, but the impact on the statistical power of the survey to detect differences between time periods should be carefully considered. However, the power of the survey can be increased by the inclusion of more than 50 individual samples and is encouraged. In particular, countries with populations greater than 50 million should include at least one additional participant per one million population over 50 million. Countries with populations well over 50 million (or with sufficient resources) are encouraged to prepare a second pooled sample (or more) if feasible.

Pooled versus Individual Samples

Because some analytical methods involve ultrapure solvents and sophisticated instrumentation, the cost of analysis may be prohibitive. For example, the cost of analyzing PCDDs, PCDFs, and dioxin-like PCBs was estimated to be US$2000 per sample when some of the earlier studies took place, although this has reduced considerably in recent years. Obviously, the analysis of pooled human milk samples is also far less expensive than the analysis of individual samples. In addition, it is easier for each donor to provide the lower volume of milk required for pooled analyses. If the purpose of the study is to estimate an average level for a population, this approach can save time and money because combining equal amounts of each sample represents a physical averaging of all the samples. However, the analysis of individual samples can provide information on the distribution of exposures and on factors possibly contributing to exposure. In addition, such data are also essential to statistically validate that two average values are indeed different based on the distributions of their individual results.

Analytical Considerations

Once a chemical of interest has been identified, the next task is to define for analytical purposes the actual residue(s) to be measured. In most cases, this will include the parent compound, but for many chemicals, the number of possible isomers may be quite large. For example, PCBs exist as 209 possible isomers; PCDDs have 75 isomers; and, PCDFs have 135 isomers. In other cases, such as DDT, degradation products are also included in the residue definition. Another complication in relation to POPs is that the potential to bind to endocrine receptors varies significantly among different POPs as well as among the isomers of the same POP. Therefore, the concentrations of various POPs must be corrected with its corresponding WHO toxic equivalence factor. Consequently, the residue definitions for PCBs, PCDDs, and PCDFs are based on a combination of not only their expected distributions, but also their relative toxic potencies.

SAFETY OF FOOD AND BEVERAGES

Halal Food Requirements

MM Chaudry, Islamic Food and Nutrition Council of America, Park Ridge, IL, USA
MN Riaz, Texas A&M University, College Station, TX, USA

Glossary

Hadith Sayings of Prophet Muhammad to denote examples for one to follow.
Halal An Arabic word meaning lawful or permitted to consume, variantly spelled as hallal, halaal, halalan, or helal.
Shari'ah Comprehensive Islamic laws governing a Muslim's life, including those of halal food laws and practices.
Sunnah Traditions of Prophet Muhammad including his sayings and practical examples of actions to teach Muslims about the observance of their faith.
Zabiha An Arabic term, literally meaning slaughtered but generally perceived as manually slaughtered by a Muslim, as opposed to mechanical slaughtering of some animals especially poultry.

Introduction

The objective of this article is to describe halal laws as they apply in the food industry, and to elaborate on ensuring the integrity of the process of making halal food including halal certification. It also highlights and emphasizes the importance of understanding how halal foods are produced, and how important its compliance is to all stakeholders, producers, marketers, regulators, and consumers. Special emphasis is on the religious significance of dietary laws for Muslims, as they are understood by the food industry in order to serve this segment of the global population exceeding 1.57 billion halal consumers.

The halal dietary laws determine which foods are lawful or permitted for Muslims. These laws are found in the Quran, the holy book and *Sunnah*, the practice of Prophet Muhammad, as recorded in the books of the traditions, called *Hadith*. Islamic law is referred to as *Shari'ah* and has been interpreted by Muslim scholars over the years. The basic principles of the Islamic laws remain definite and unaltered. However, their interpretation and application may change according to the time, place, and circumstances. Besides the two basic sources of Islamic law, the Quran and *Sunnah*, two other sources of jurisprudence are used in determining the permissibility of food, when a contemporary situation is not explicitly covered by the first two basic sources; the first is *Ijma* meaning a consensus of legal opinion, and second is *Qiyas*, meaning reasoning by analogy. In the latter case the process of *Ijtihad*, or exerting oneself fully to arrive at an answer to the problem, is used.

Current issues of genetically modified organisms (GMOs), animal feed, hormones, etc., are discussed in the light of these two concepts and several other lesser sources of Islamic jurisprudence. Unconventional sources of ingredients, synthetic materials, and innovations in animal slaughter and meat processing are some of the issues Muslim scholars are dealing with in helping the consumers make informed choices.

It is important to note that, the health aspects of eating are an important consideration with halal food laws. These laws are viewed by the community as divine guidance without a need for explanations. Only in recent times some people have felt a need to try to justify them as health laws.

Basis of Halal Food Laws

Why do Muslims follow the halal dietary laws? The main reason for the observance of halal food laws in the Islamic faith is to follow the Divine Orders.

> "O ye who believe! Eat of the good things wherewith We have provided you, and render thanks to God if it is He whom ye worship." (Quran II: 172)

God reminds the believers time and again in the Holy Scripture to eat what is 'Halalan Tayyiban,' meaning 'permitted and good or wholesome.'

> "O, Mankind! Eat of that which is Lawful and Wholesome in the earth..." (Quran II: 168)

> "Eat of the good things. We have provided for your sustenance, but commit no excess therein." (Quran XX: 81)

Again in the Quran, Chapter VI, titled the Cattle, Muslims are instructed to eat the meat of animals on which God's name

 doi:10.1016/B978-0-12-378612-8.00400-5

has been invoked. This is generally interpreted as meaning that an invocation has to be made at the time of slaughtering an animal.

> "Eat of that over which the name of God hath been mentioned, if ye are believers in His revelations." (Quran VI: 119)

Although Muslims eat what is permitted specifically or by implication, albeit without comment, they avoid eating what is specifically disallowed, such as:

> "And eat not of that whereupon God's name hath not been mentioned, for lo, it is abomination. Lo! The devils do inspire their minions to dispute with you. But if ye obey them, ye will be in truth idolaters." (Quran VI: 121)

The majority of Islamic scholars are of the opinion that this verse deals with proper slaughtering of allowed animals.

As Muslim dietary laws relate to divine permissions and prohibitions, if anyone observes these laws, he/she is rewarded in the hereafter and if anyone violates these laws, he/she may receive punishment accordingly. The rules for those foods that are not specifically prohibited may be interpreted differently by various scholars. The things that are specifically prohibited are just a few in numbers, as summarized in the following verse:

> "Forbidden unto you are: carrion and blood and swine flesh, and that which hath been dedicated unto any other than God, and the strangled, and the dead through beating, and the dead through falling from a height, and that which hath been killed by the goring of horns, and the devoured of wild beasts save that which ye make lawful, and that which hath been immolated to idols. And that ye swear by the divining arrows. This is abomination." (Quran V: 3)

Although these permissions and prohibitions as a divine injunction are enough for a Muslim to observe the laws, it is believed that the dietary laws are based on health reasons that suggest impurity or harmfulness of prohibited foods.

The Halal Market

Why are we concerned about halal in the secular world? Because halal is an important component of the food business. Most people, even in the food industry, are not aware of the breadth of foods that are under religious supervision. This section provides a background on the economic aspects that make it important for the food industry to have a better understanding of halal.

The Muslim population in the US is developing a stronger marketplace presence each year. Over the past 30 years many halal markets and ethnic stores have sprung up, mainly in the major metropolitan areas. Most of the eight million Muslims in North America observe halal laws, particularly the avoidance of pork, but the food industry has, for the most part, ignored this consumer group. Although there are excellent opportunities to be realized in the North American halal market, even more compelling opportunities exist on a worldwide basis as the food industry moves to a more global business model. The number of Muslims in the world is more than 1.57 billion people and trade in halal food products is approximately $661.6 billion. Several recent reports estimate the Muslim population to be higher than 1.60 billion globally and estimate the global halal trade at $2.3 trillion total and $661.6 billion for food alone. Many countries of South Asia, Southeast Asia, the Middle East, and Northern Africa have predominantly Muslim populations. Although only approximately 15% of India's population is Muslim, it is the second largest Muslim country in the world after Indonesia. In many countries halal certification has become necessary for products to be imported.

Although some Muslims purchase kosher food in the US, these foods, do not always meet the needs of the Muslim consumer. The most common areas of concern for the Muslim consumer when considering the purchase of kosher products are the use of various questionable gelatins in products produced by more lenient kosher supervisions and the use of alcohol as a carrier for flavors, as well as a food ingredient. The details of both ideas will be developed later in this article.

In recent years, many other universities are also exploring kosher/halal and multicultural food options.

Discussion on Halal Food Laws

The halal dietary laws define food products as halal or permitted and haram or prohibited, whereas a few items may fall into *Makrooh* or detestable category. The Islamic food laws deal with the following five major issues; all but the last one are in the animal kingdom.

1. Prohibited animals.
2. Prohibition of blood.
3. Method of slaughtering/blessing.
4. Prohibition of carrion.
5. Prohibition of intoxicants.

The Islamic dietary laws are derived from the Quran, a revealed book; the *Hadith*, the traditions of Prophet Muhammad; and through the extrapolation and deduction from the Quran and *Hadith* by Muslim jurists.

There are 11 generally accepted principles pertaining to halal and haram in Islam for providing guidance to Muslims in their customary practices.

The basic principle is that all things created by God are permitted, with a few exceptions that are prohibited. Those exceptions include pork, blood, and meat of animals that have died of causes other than proper slaughtering, food that has been dedicated or immolated to someone other than God, alcohol, intoxicants, and inappropriately used drugs.

1. To make lawful and unlawful is the right of God alone. No human being, no matter how pious or powerful, may take it into his hands to change it.
2. Prohibiting what is permitted and permitting what is prohibited is similar to ascribing partners to God. This is a sin of the highest degree that makes one fall out of the sphere of Islam.

3. The basic reasons for the prohibition of things are due to impurity and harmfulness.
4. A Muslim is not supposed to question exactly why or how something is unclean or harmful in what God has prohibited. There might be obvious reasons and there might be obscure reasons. The underlying principle behind the prohibitions remains the Divine order: "FORBIDDEN UNTO YOU ARE....".
5. What is permitted is sufficient and what is prohibited is then superfluous. God prohibited only things that are unnecessary or dispensable while providing better alternatives. People can survive and live better without consuming unhealthy carrion, pork, blood and the root of many vices, and alcohol.
6. Whatever is conducive to the prohibited is in itself prohibited. If something is prohibited, anything leading to it is also prohibited.
7. Falsely representing unlawful as lawful is prohibited. It is unlawful to make flimsy excuses, to consume something that is prohibited, such as drinking alcohol for supposedly medical reasons.
8. Good intentions do not make the unlawful acceptable. Whenever any permissible action of the believer is accompanied by a good intention, his action becomes an act of worship. In the case of haram, it remains haram, no matter how good the intention or how honorable the purpose may be. Islam does not endorse employing a haram means to achieve a praiseworthy end. The religion indeed insists not only that the goal be honorable but also means chosen to achieve it be lawful and proper. Islamic laws demand that the right should be secured solely through just means.
9. Doubtful things should be avoided. There is a gray area between clearly lawful and unlawful. This is the area which falls under doubtful. Islam considers it an act of piety for the Muslims to avoid doubtful things, for them to stay clear of the unlawful. Prophet Muhammad said:

> "The halal is clear and the haram is clear. Between the two there are doubtful matters concerning which people do not know whether they are halal or haram. One who avoids them in order to safeguard his religion and his honor is safe, while if someone engages in a part of them, he may be doing something haram."

10. Unlawful things are prohibited to everyone alike. Islamic laws are universally applicable to all races, creeds, and sexes. There is no favored treatment of a privileged class. Actually, in Islam, there are no privileged classes; hence, the question of preferential treatment does not arise. This principle applies not only among Muslims but also between Muslims and non-Muslims.
11. Necessity dictates exceptions. The range of prohibited things in Islam is quite limited, but emphasis on observing the prohibitions is very strong. At the same time, Islam is not oblivious to the exigencies of life, to their magnitude, or to human weakness and capacity to face them. A Muslim is permitted, under the compulsion of necessity, to eat a prohibited food to ensure survival – but only in quantities sufficient to remove the necessity and avoid starvation.

Prohibited and Permitted Animals

Meat of pigs, boars, and swine is strictly prohibited, as are the carnivorous animals such as lions, tigers, cheetahs, cats, dogs, and wolves. Also prohibited are birds of prey such as eagles, falcons, osprey, kites, and vultures.

Meat of domesticated animals like ruminants with split hooves, for example, cattle, sheep, goat, and lamb, is allowed for food, as are camels and buffaloes. Also permitted are the birds that do not use their claws to hold down food, such as chickens, turkeys, ducks, geese, pigeons, doves, partridges, quails, sparrows, emus, and ostriches. Some of the animal and birds are permitted only under special circumstances or with certain conditions. Horsemeat may be permitted for consumption under some distressing conditions, discussion of which is beyond the scope of this article. The animals fed unclean or filthy feed, for example, formulated with biosolids (sewage) or protein from tankage, must be quarantined and placed on clean feed for a period varying from 3 to 40 days to cleanse their systems before slaughter.

Food from the sea, namely, fish and seafood, are the most controversial among various denominations of Muslims. Certain groups, particularly Shi'a, only accept fish with scales as halal, whereas others consider as halal everything that lives in the water all the time. Consequently, prawns, lobsters, crabs, and clams are halal but may be detested (*Makrooh*) by some and hence, not consumed. Animals that live both in water and on land, amphibians, such as frogs, turtles, crocodiles, and seals are also not consumed by the majority of observant Muslims.

There is no clear status of insects established in Islam except that the locust is specifically mentioned as halal. Insects are generally considered neutral. However, from deduction of the laws, it seems that both helpful insects like bees, ants, and spiders, and harmful or dirty creatures like lice, flies, and mosquitoes are all prohibited as food. Among the by-products from insects, the use of honey was very highly recommended by Prophet Muhammad. Other products like royal jelly, wax, shellac, and carmine are acceptable to be used without restrictions by most; however, some may consider shellac and carmine to be questionable.

Eggs and milk from permitted animals are also permitted for Muslim consumption. Eggs from chicken, ducks, geese, etc. and milk from cows, goats, sheep, and buffaloes are halal.

Prohibition of Blood

According to the Quranic verses, blood that pours forth is prohibited for consumption. It includes blood of permitted and nonpermitted animals alike. Liquid blood is generally not offered for sale or consumed by Muslims or non-Muslims, except in certain tribal areas, but products made from blood are available. There is general agreement among Muslim scholars that anything made from blood is unacceptable. Products like blood sausage and ingredients like blood albumin are either haram or questionable at best, and should be avoided for product formulations.

Proper Slaughtering of Permitted Animals

There are special requirements for slaughtering the animal:

- An animal must be of a halal species.
- It must be slaughtered by a competent Muslim of sound mind.
- God's name must be invoked on each animal at the time of slaughter.
- Slaughter must be done by cutting the throat in a manner that induces rapid and complete bleeding, resulting in the quickest death. Generally accepted method is to cut at least three of the four passages, i.e., carotids, jugulars, trachea, and esophagus. Some Islamic scholars do accept mechanical slaughter, particularly of poultry. However, in recent years the trend has reverted toward manual slaughter of these animals.

The meat of animals thus slaughtered is called zabiha or dhabiha meat. "Verily God has prescribed proficiency in all things. Thus, if you kill, kill well; and if you perform dhabiha, perform it well. Let each one of you sharpen his blade and let him spare suffering to the animal he slays."

Islam places great emphasis on the gentle and humane treatment of animals, especially before and during slaughter. Some of the conditions include giving the animal proper rest and water; avoiding conditions that create stress; not sharpening the knife in front of the animals; and using a very sharp knife to slit the throat. Only after the blood is allowed to drain completely from the animal and the animal has become lifeless can the dismemberment, cutting off horns, ears, legs, etc. commence. Animal-derived food ingredients like emulsifiers, tallow, and enzymes must be made from animals slaughtered by a Muslim, for them to be halal. There are some differences between Sunni and Shi'a Muslims as well as some cultural differences regarding slaughtering animals.

Hunting of permitted wild animals, like deer, and birds like doves, pheasants, and quail is permitted for the purpose of eating but not merely for deriving pleasure out of killing an animal. Hunting during the pilgrimage to Mecca and within the defined boundaries for pilgrimage is prohibited. Hunting is permitted with any tools, for example, guns, arrows, spears, or trapping. Trained dogs may also be used for catching or retrieving the hunt. The name of God must be invoked at the time of shooting a bullet or releasing the tool rather than after catching the hunt. The animal has to be bled by slitting the throat as soon as it is caught. If the blessing is made at the time of pulling the trigger or shooting an arrow and the hunted animal dies before the hunter reaches it, it would still be halal as long as slaughter is performed and some blood comes out. Fish and seafood may be hunted or caught by any reasonable means available as long as it is done humanely and invoking God's name is not required in such conditions.

The requirements of proper slaughtering and bleeding are applicable to land animals and birds. Fish and other creatures that live in water need not be ritually slaughtered. Similarly there is no special method of killing the locust.

The meat of the animals that die of natural causes; for example, diseases, being gored by other animals, being strangled, falling from a height, through beating, or killed by wild beasts; is unlawful to be eaten, unless one saves such animals by slaughtering before they actually become lifeless. Fish that dies naturally and is floating on water or lying out of the water is still halal as long as it does not show any signs of decay or deterioration.

Meat of Animals Killed by Christians or Jews

There has been considerable discussion and controversy among Muslim consumers as well as Islamic Scholars about the permissibility of consuming meat of animals killed by the Christians and Jews, known in the Quran as People of the Book. The issue focuses on whether meat prepared in the manner practiced by either faith would be permitted for Muslims.

In the Holy Quran, this issue is presented only once in Chapter V, verse 5, in the following words:

> "This day all good things are made lawful for you. The food of those who have received the Scripture is lawful for you, and your food is lawful for them."

This verse addresses the Muslims and seems to establish a social context where Muslims, Jews, and Christians could interact with each other. It addresses Muslims saying that food of the People of the Book is lawful for them and Muslim food is lawful for Jews and Christians. In most discussions, scholars try to deal with the first part, food of the People of the Book, and avoid the second part, food of Muslims, altogether, leaving that decision to the People of the Book.

The majority of Islamic scholars are of the opinion that the food of the People of the Book must meet the criteria established for halal and wholesome food including proper slaughter of animals. They believe that the following verse establishes a strict requirement for Muslims.

> "And eat not of that whereupon God's name hath not been mentioned, for lo! It is abomination." (Quran VI: 121)

However, some Islamic scholars are of the opinion that the above verse does not apply to the food of the People of the Book and there is no need to mention the name of God at the time of slaughtering. It is up to the regulatory agencies in the halal food importing countries, halal certifiers for export or domestic consumption, or the individual Muslim consumers to decide how to interpret this verse.

Prohibition of Alcohol and Intoxicants

Consumption of alcoholic drinks as intoxicants is prohibited according to the Quran (V: 90–91), as follows:

> "O you who believe! Fermented drinks and games of chance, and idols and divining arrows are only an infamy of Satan's handiwork. Leave it aside in order that you may prosper. Only would Satan sow hatred and strife among you, by alcohol, and games of chance, and turn you aside from the remembrance of God, and from prayer: Will you not, therefore, abstain from them?"

The Arabic term used for alcohol in the Quran is *khamr*, which means, that which has been fermented, and implies not

only to alcoholic beverages like wine, beer, whiskey, and brandy, but also to imply all things that intoxicate or affect one's thought process. Although there is no allowance for added alcohol in any beverage like soft drinks, small amounts of alcohol contributed from food ingredients may be considered an impurity and hence ignored. Synthetic or grain alcohol may be used in food processing for extraction, precipitation, dissolving, and other reasons, as long as the amount of alcohol remaining in the final product is very small, generally below 0.1%. Each importing country may have its own guidelines, which must be understood by the exporters and strictly adhered to.

In the West, food may be cooked in alcohol to enhance the flavor or impart distinctive flavor notes. Wine is the most common form of alcohol used in cooking. Although one may think that all the added alcohol evaporates or burns off during cooking, the fact is that it does not. The alcohol retained in the food products varies depending on the cooking method.

Even after cooking for 2.5 h, up to 5% alcohol remains in the food. Although there is little chance of intoxication by eating such food, the use of alcoholic drinks in cooking is categorically discouraged.

Food Preparation, Processing, and Sanitation

There are no restrictions about cooking in Islam, as long as the kitchen is free from haram foods and ingredients. In food companies, haram materials should be kept segregated from halal materials. The equipment used for nonhalal products has to be thoroughly cleansed using proper techniques of acids, bases, detergents, and hot water. It is recommended that food processors use dedicated equipment and utensils for producing halal food.

Gelatin

Important in many food products, gelatin is probably the most controversial of all modern halal ingredients. Gelatin can be derived from pig skin, cattle bones, and cattle hides. In recent years, some gelatins from fish skins have also entered the market. Fish gelatins can be produced halal with proper supervision, and acceptable to almost all of the mainstream religious supervision organizations. Most currently available gelatins – even if called kosher – are not acceptable to the mainstream US kosher supervision organizations and Islamic scholars. Many are, in fact, totally unacceptable to halal consumers because they may be pork-based gelatin. All major manufacturers and some smaller ones are currently producing certified halal gelatin from cattle bones and hides of animals that have been slaughtered by Muslims.

Biotechnology

Ingredients made through biotechnology and genetic engineering of organisms, GMO ingredients have gained acceptance by Islamic scholars since the production of vegetable chymosin or synthetic rennet. The basis for this acceptance includes the fact that the genetic material is isolated from permitted animal and copied onto microbial systems to produce nature identical ingredients. Thus, the original source of the gene is essentially lost by the time it enters the food products. The production conditions and media for the microbial growth meet halal requirements. Many food ingredients and crops are now produced through genetic modifications and very few questions are raised about their acceptance.

Dealing with Halal Supervision Agencies

In practical terms, the food industry works with halal supervision agencies to obtain permission to use the supervision agency's trademark symbol on their products. In this way, the industry can make claims in the marketplace that are credible to those intentionally purchasing these products. Halal supervision is taken on by a company to expand its market opportunities, domestically as well as internationally. What criteria should a company use to select a supervision agency? Supervision fees must be taken into account, and the agency's name recognition is a consideration. Out of hundreds of halal certifications around the globe, only a handful are accepted by importing countries like Malaysia, Indonesia, Singapore, United Arab Emirates, and other Middle Eastern countries. Besides credibility and acceptance, other important considerations include:

1. Responsiveness in handling paperwork; providing Muslim inspectors at the plants on a timely basis; and in doing routine inspections at a defined frequency during the year.
2. Willingness to work with the company on problem solving.
3. Ability to clearly explain their halal standards and their fee structure.
4. Whether or not an agency's halal standards meet the company's needs in the marketplace; meaning the acceptability among the consumers and importers.

Many halal certification bodies have sprung up throughout the world; some of them are nonprofit organizations, whereas other government agencies, private for profit businesses, multinational quality assurance corporations, and even some private individuals. Some groups and individuals have resorted to certifying their own products. If one has any interest in exporting to Muslim countries or countries with a significant Muslim population, it is extremely important to know which countries will accept the supervision of which agencies.

In recent years we have started to see products that have dual halal and kosher certification. The first of such products were the ready-to-eat meals for the US Military (meals ready-to-eat, MREs), but the market has expanded to other industrial and consumer products. Some of the civilian versions of the MREs are now available in long-term shelf-stable (nonrefrigerated) form that makes them convenient for transport, store, and use. Only vegetarian and dairy products have received dual certification.

Ingredient companies should be particularly careful in selecting a supervision agency. They should try to use a mainstream halal supervision agency because most halal food manufacturing companies will require such supervision. The

ability to sell to as many customers as possible requires a broadly acceptable agency.

The halal symbol of the certifying agency or individual doing the certification may appear on the packaging. In some industrial situations, where halal and nonhalal products are similar, some sort of color coding of product labels and packages may also be used. Most of these religious supervision symbols are trademarks that are duly registered. In many countries a generic halal symbol, i.e., the word halal in Arabic in a circle has been used indiscriminately. Muslim consumers do not have much faith in such a symbol. In North America some small companies have used similar generic markings or just the word halal or letter H to signify that food is halal, but such symbols are not widely accepted. The Islamic Food and Nutrition Council of America uses a registered trademark logo of the letter 'M' inside a closed crescent. Many other halal logos have started to appear on packages in North America, United Kingdom, Pakistan, and many other countries. Some countries like Indonesia, Malaysia, Brunei, Singapore, and Thailand have central halal control bodies, each with their unique logo. As the volume of halal products offered in local and international markets grows, it is expected that determining the standards for a halal certification will become more complex.

Animal Welfare Issues

Lately, animal welfare has been in the news a great deal, especially in Europe, where the European Union has formulated a set of guidelines especially for religious slaughter of animals. The World Organisation for Animal Health (OIE), an international organization comprising 167 member countries has also developed guidelines on animal welfare that include humane treatment of animals during transport and slaughter. According to OIE guidelines both kosher and halal conventional slaughter are considered as humane, meeting animal welfare considerations. Some of the largest fast food chains have adopted a set of animal welfare standards that determine the purchasing requirements of products they use. In the USA, the most widely recognized animal welfare standard was developed by the American Meat Institute; however, other industry organizations and even individual food chains claim to have their own standards. In Islam, animal welfare is not limited to slaughter only; it starts with raising the animals on the farm and is carried through transport and slaughter. The concept of proper treatment of all types of animals is very comprehensive and deep rooted in the faith of Islam.

Glossary

B'de-eved After the fact.
Beit Yosef No lung adhesions.
Chai Life or the number 18.
Chalef Jewish religious slaughter knife.
Challah Special bread offering.
Chodesh New flower.
Cholev Yisroel Jewish milk.
Chometz Prohibited grains for Passover (wheat, rye, oats, barley and spelt).
Gevinas Yisroel Jewish cheese.
Glatt No more than two lung adhesions on large animals.
Halacha Jewish religious law.
Halal Muslim dietary laws.
Kitnyos Rabbinically prohibited materials for Passover.
Kosher Jewish dietary laws.
L'chatchilla Before the fact.
Mashgiach Jewish religious supervisor.
Matzos Unleavened bread for Passover.
Mevushal Heated grape juice and wine.
Mishnah The oral law as written down in the Talmud.
Pareve Neither meat nor dairy.
Pas Yisroel Jewish baking.
Schmura Watched wheat for Passover.
Shochet Jewish religious slaughterman.
Talmud The codification and commentary on the oral law.
Torah The written law, the first five books of the Hebrew scriptures.
Tovel To immerse vessels in water.
Treife Not kosher.
Yashon Old flour.

Introduction

The objective of this paper is to describe the kosher laws as they apply in the food industry, particularly the US with a special emphasis on how these laws might affect food safety and related issues. To understand their potential impact on food safety, one must have some understanding of how kosher foods are produced, and how important kosher compliance is to consumers, i.e., its impact on spiritual health. According to the World Health Organization, health is defined as a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity. Thus, a violation of the kosher laws by those companies making and marketing kosher foods represents a breach of faith that can negatively impact the consumer, i.e., dependent on these products for their continued spiritual health and social well-being.

[☆] Preliminary note: The information in this article is as accurate as possible at the time of submission (August 2011). However, the final decision on any application rests with the religious authorities providing supervision. The ruling of the religious authorities may differ from the information presented here.

The Kosher Laws

The kosher (kashrus) dietary laws determine which foods are 'fit or proper' for consumption by Jewish consumers who observe these laws. The laws are Biblical in origin, coming mainly from the original five books of the Holy Scriptures, the Torah, which has remained unchanged since then but responds to modern needs. At the same time that Moses received the Ten Commandments on Mount Sinai, Jewish tradition teaches that he also received the oral law, which was eventually written down many years later as a text known as the Mishnah, which was then incorporated into the Talmud, which is the major Jewish law book. This oral law is as much a part of Biblical law as the written text. Over the next 3500 years, the meaning of the Biblical kosher laws have been interpreted and extended by the rabbis to protect the Jewish people from violating any of the fundamental laws, and to address new issues and technologies. The system of Jewish law is referred to as 'halacha.'

Why do Jews follow the kosher dietary laws? Many explanations have been given. The following explanation by Rabbi I. Grunfeld summarizes the most widely held ideas about the subject.

These food laws are viewed by the Jewish community as given to the community by G-d without a need for explanation. Only in modern times have some people felt a need

 doi:10.1016/B978-0-12-378612-8.00401-7

to try to justify them as health laws. For example, the claim that it was necessary to protect Jews from trichinosis in pork was a reason for these laws. There are only two problems with this idea – apparently mummified pork obtained from the Egyptian pyramids did not have any signs of the trichinosis cyst and the incubation period for trichinosis is 10–14 days – making it very unlikely that the cause and effect needed for such a rule would have been figured out at that time.

> "And ye shall be men of a holy calling unto Me, and ye shall not eat any meat that is torn in the field" (Exodus XXII:30). Holiness or selfsanctification is a moral term; it is identical with...moral freedom or moral autonomy. Its aim is the complete selfmastery of man."

To the superficial observer it seems that men who do not obey the law are freer than law-abiding men, because they can follow their own inclinations. In reality, however, such men are subject to the most cruel bondage; they are slaves of their own instincts, impulses, and desires. The first step towards emancipation from the tyranny of animal inclinations in man is, therefore, a voluntary submission to the moral law. The constraint of law is the beginning of human freedom.... Thus the fundamental idea of Jewish ethics, holiness, is inseparably connected with the idea of Law; and the dietary laws occupy a central position in that system of moral discipline which is the basis of all Jewish laws.

> "The three strongest natural instincts in man are the impulses of food, sex, and acquisition. Judaism does not aim at the destruction of these impulses, but at their control and indeed their sanctification. It is the law which spiritualizes these instincts and transfigures them into legitimate joys of life."

The Kosher Market

Why are we concerned about kosher in the secular world? Because kosher is an important component of the food business (e.g., in the US approximately 40% of packaged goods are kosher certified) and impacts how a company does its food processing, with potential positive and negative benefits to food safety. Most people, even in the food industry, are not aware of the breadth of foods that are under religious supervision. This section provides a short background on the economic aspects that make it important for the food industry to have a better understanding of kosher.

The kosher market according to Integrated Marketing, an advertising agency specializing in the kosher food industry, comprises greater than 100 000 products in the US, approximately 250 billion dollars worth of products are estimated to have a kosher marking on them. The deliberate consumers of kosher food, i.e., those who specifically look for the kosher mark before purchasing, are estimated to be greater than 10 million Americans. They are purchasing almost 15 billion dollars worth of kosher product. Annually greater than 10 000 companies produce kosher products and the average US supermarket has 13 000 kosher products. Less than 1/3 (possibly as low as 20%) of the kosher consumers are Jewish (900 000 year-round consumers). Other consumers who at times find kosher products helpful in meeting their dietary needs include Muslims, along with others such as Seventh Day Adventists, vegetarians, vegans, people with various types of allergies – particularly to dairy, grains, and legumes (the latter two are addressed with Passover products) – and general consumers who value the quality of kosher products, even though there is rarely a one-to-one correlation between kosher and these consumers' needs.

Kosher

The Kosher Dietary Laws

The all year around kosher dietary laws predominantly deal with three issues, all focused on the animal kingdom (but because of these laws, vegetarian and vegan products are carefully checked to be sure no slaughtered animal products have come in contact with these foods):

A. The Allowed Animals,
B. The Prohibition of Blood, and
C. The Prohibition of Mixing of Milk and Meat.

Additionally, for the week of Passover (in late March or April) restrictions on 'chometz,' the prohibited grains (wheat, rye, oats, barley, and spelt) in other than unleavened form – and the rabbinical extensions of this prohibition – lead to a whole new set of regulations, focused in this case on the plant kingdom.

In this paper we will also discuss additional laws dealing with special issues such as grape juice, wine, and alcohol derived from grape products; Jewish supervision of milk; Jewish cooking, cheese making, and baking; equipment kosherization; purchasing new equipment from nonJews; and old and new flour.

The kosher laws are an internally consistent logic system and have an implied 'science' behind them – which may or may not agree with modern science. This system is the basis upon which rabbis work through problems and come up with a solution for new issues brought to their attention through a process of asking questions.

Allowed Animals

Ruminants with split hoofs that chew their cud, the traditional domestic birds, and fish with fins and removable scales are generally permitted. Pigs, wild birds, ostriches, and fish without removable scales are prohibited as are all crustacean and molluscan shellfish. Almost all insects are prohibited such that carmine and cochineal, which are used as natural red pigments, are not permitted in kosher products by most rabbinical supervisors. However, honey and shellac (lac resin) are permitted as will be discussed later in this section.

Four classes of prohibited animals are specifically described in the Torah. These are simply those animals that have one kosher sign but not both. These animals are no more or less nonkosher than other nonkosher animals; none are kosher. They are listed specifically only to clarify the text. In modern times the prohibition of pork has often been the focus with respect to both the kosher and halal laws, because pork is such a major item of commerce in many parts of the world.

With respect to poultry, the traditional domestic birds are kosher but birds in the rattrie category (ostrich, emu, and

rhea) are not kosher as the ostrich is specifically prohibited in the Bible (Lev. XI:16).

The only animals from the sea that are permitted are those with fins and scales. All fish with scales have fins, so the focus is on the scales. These must be visible to the human eye and must be removable from the fish skin. A few fish remain controversial, especially swordfish, whose scales do not seem to belong to any of the biologists standard scale types. The Conservative Movement also permits sturgeon, which most Orthodox authorities consider nonkosher.

Most visible insects are not kosher. The exception includes a few types of grasshoppers, which are acceptable in the parts of the world where the tradition of eating them has not been lost. The recent development of exhaustive cleaning methods to prepare prepackaged salad vegetables, which was driven in part by the desire to receive kosher certification for such products, eliminates a lot of visible insects so products are available without requiring further extensive special inspection procedures. Presumably all of this produce washing and insect removal also should make these products cleaner and safer for consumers, especially with some of the concerns for hand washing by workers in the fields. Kosher consumers have appreciated the use of pesticides to keep products insect free. Modern integrated pest management (IPM) programs that permit an increase in the level of insect infestation in the edible portions of fruits and vegetables can cause problems for the kosher consumer. Honey and other products from honey bees are covered by a unique set of laws that permits honey and beeswax. Most rabbis extend this permission to the use of lac resin or shellac, which is used in candy and fruit coatings to provide a 'shine.'

Prohibition of Blood

Ruminants and fowl must be slaughtered according to Jewish law by a specially trained religious slaughterman (shochet) using a special knife designed for the purpose (chalef). Thus, any wild animal or bird would have to be captured alive and then slaughtered.

The knife must be extremely sharp and have a very straight blade, i.e., at least twice the diameter of the neck of the animal to be slaughtered. It is the process itself, and the strict following of the law, that makes a product kosher, and not the presence or absence of a blessing over the food. However, before a slaughter session the shochet does make a blessing. The animal is not stunned before slaughter. If the slaughter is done in accordance with Jewish law and with the highest standards of modern animal handling practices, the animal will die without showing any signs of stress. In 1958, the US Congress declared kosher slaughter and similar systems, (e.g., such as halal) to be humane, but included an exemption for preslaughter handling of the animal before kosher and halal slaughter. Thus, when done right religious slaughter meets the standards for good animal welfare. Whether more blood is removed during slaughter by religious slaughter remains a controversial question for which more data is needed.

Slaughtered animals are subsequently inspected for visible internal organ defects by rabbinically-trained inspectors. If an animal is found to have a defect, the animal is deemed unacceptable and becomes treife. There is no 'trimming' of defective portions as generally permitted under secular law. This is viewed by some consumers as a reason to choose kosher, i.e., problem animals are eliminated from the kosher food supply. However, the concern in modern times is for invisible pathogens, which both the rabbinical and governmental systems were not designed to detect. The general rule is that the defect would not lead to a situation where the animal could be expected to die within a year. Some rabbis invoke these rules in dealing with issues related to veterinary practices, example, injections into certain parts of the animal's anatomy such as the neck of a chicken.

As the major site of halachic defects, the lungs must always be inspected. Other organs are spot-checked or examined when a potential problem is observed. At this time we do not have a full understanding of what animal handling practices lead to higher incidences of lung adhesions, although pneumonia in the calf is certainly one consideration. However, the concept is that kosher leads to the use of healthier animals. For practical reasons, i.e., because they cannot pass this inspection, culled dairy cows are not generally slaughtered and so the threat of mad cow disease (BSE) is reduced.

Meat and poultry must be further prepared by properly removing certain veins, arteries, prohibited fats, blood, and the sciatic nerve. In practical terms this means that only the front quarter cuts of kosher red meat are used in the US and most Western countries. These are the cheaper cuts and have at times led to the use of higher US Department of Agriculture (USDA) meat grades, example, prime and choice, which are more highly marbled, a possible health concern.

To further remove the prohibited blood, red meat and poultry must then be soaked and salted within 72 h of slaughter. If this is not possible, then under some circumstances the meat may be washed and this wash procedure may be repeated for up to two more times, each time within 72 h of the previous washing. The actual soaking is done for a half hour in cool water, thereafter, the salting is done for one hour with all surfaces, including cut surfaces and the inside cavity of a chicken, being covered with ample amounts of salt. The salted meat is then rinsed three times. The salted meat must be able to drain throughout and all the blood being removed must flow away freely.

Once the meat is properly koshered, any remaining 'red-liquid' is no longer considered 'blood' according to halacha and the meat can be used without further concern for these issues.

Work by Jim Marsden's group at Kansas State University has shown that this salting process does lead to a lower bacterial count so that the process may in fact be an antimicrobial treatment. The other antimicrobial treatments being used for meat safety are receiving mixed reviews from the rabbis. The use of heat (steam or hot water) and some of these chemicals, particularly those that are acidic, before kosher salting and soaking (which usually doesnot occur until after the meat has been chilled) may not be permitted.

The salt used for koshering must be of a crystal size, i.e., large enough that the crystals will not dissolve within the hour and must be small enough to permit complete coverage of the meat. The salt industry refers to this size crystal as 'kosher' salt. Although most salt is religiously kosher, the term 'kosher' in this case is referring to the grain size. The specific process of salting

and soaking meat to make it ready for use is also referred to as 'koshering' meat.

Because of its high blood content, liver cannot be soaked and salted, but must instead be broiled to at least over half cooked using special equipment reserved for this purpose. The liver is then rinsed, after which the liver can be used in any way the user wishes.

Some concern has been raised about the salt level in kosher meat given the interest in low salt diets. Note that only the surfaces are salted, generally using primal cuts, i.e., 20–40 lb pieces of meat, and that the penetration of the salt is less than a half centimeter in red meat (NY Department of Agriculture and Markets, personal communication). Many pieces of meat, as consumed, have therefore not been directly subjected to the salt treatment. If salt content in a diet is a very important consideration, then one should cut off all surfaces and not use any of the drippings that come out during cooking. However, much of the salt that goes into the meat at the surface is lost during cooking.

Any ingredients or materials that might be derived from animal sources are generally prohibited because of the difficulty of obtaining them from kosher animals. This includes many products that might be used in foods and dietary supplement, such as emulsifiers, stabilizers, and surfactants, particularly those materials that are fat-derived. Very careful rabbinical supervision would be necessary to assure that no animal-derived ingredients are included in kosher food products. Almost all such materials are available in a kosher form derived from plant oils. A possible exception might be a normative mainstream gelatin, which is now being produced from kosher beef hides or fish (see the Section Gelatin). Also some rennet, the cheese-coagulating enzyme, is obtained from the dried fourth stomach of a kosher slaughtered milk-fed calf, but the regular supply is not acceptable. Biotechnology derived chymosin is generally kosher (see the Section Biotechnology).

Prohibition of Mixing of Milk and Meat

> "Thou shalt not seeth the kid in its mother's milk." (Exodus XXIII:19, Exodus XXXIV:26, Deuteronomy XIV:21)

This passage appears three times in the Torah and is therefore considered a very serious admonition. As a result, the law cannot be violated even for nonfood uses such as pet food. Neither can one derive benefit from such a mixture. The meat side of the equation has been rabbinically extended to include poultry and religiously slaughtered game (not fish) as both meat and poultry need to be inspected, deveined, salted, and soaked. The dairy side includes all milk derivatives.

To keep meat and milk separate in accordance with kosher law requires that the processing and handling of all materials and products fall into one of three categories:

1. A meat product,
2. A dairy product, or
3. A neutral product called 'pareve,' 'parve,' or 'parev.'

The pareve category includes all products that are not classified religiously as meat or dairy. All plant products are pareve along with eggs, fish, honey, and lac resin (shellac). These pareve foods can be used with either meat products or dairy products. However, if they are mixed with meat or dairy they take on the identity of the product they are mixed with, i.e., an egg in a cheese soufflé becomes dairy.

A special set of rules applies to fish. Fish can be eaten at the same meal at which meat is eaten, but it cannot be mixed directly with the meat. The dishes used with the fish are generally kept separate and rinsed before they are used with meat, or *vice-versa*. The original law in the Talmud speaks of a specific concern that one particular type of fish caused people to get sick when they mixed that fish with meat. This rule is a very specific exception to the generalization that kosher laws are not health laws, but this prohibition for all fish (because no one can determine what was the original fish mentioned in Talmud) is a rabbinical extension and not a Biblical mandate. Another exception with respect to handling fish: One of the very traditional Chassidic Orthodox groups, Lubavitch or Chabad, also has a tradition of not mixing milk with fish, example, not permitting a fish gelatin to be used in yogurt.

To assure the complete separation of milk and meat, all equipment, utensils, pipes, steam, etc. must be of the properly designated category. If plant materials, like fruit juices, are run through a dairy plant, they would be considered dairy under kosher law. Some kosher supervision agencies would permit such a product to be listed as 'dairy equipment (D.E.)' rather than 'dairy.' The D.E. tells the consumer that it does not contain any intentionally added dairy ingredients, but that it was made on dairy equipment. (See the Section Kosher and Allergies) There is also a 'meat equipment (M.E.)' designation. A significant wait is normally required to use a product with dairy ingredients after one has eaten meat. This can range from 1 to 6 h depending on the customs of the area from which the husband came. With the D.E. listing, the consumer can use the D.E. product immediately before or after a meat meal but not WITH a meat meal. Following dairy the wait before eating meat is much less, usually from a 'rinse of the mouth' with water to one hour. Certain dairy foods do require the full wait of 3 to 6 h, i.e., when a hard cheese is eaten, the wait is the same as that for meat to dairy. A hard cheese is defined as a cheese that has been aged for greater than six months or one, i.e., particularly dry and hard like many of the Italian cheeses. Thus, most companies producing kosher cheese usually age their cheese for less than six months, which may limit the quality, although with proper consumer labeling information longer aging can be done as this is not a religious requirement but simply affects the waiting times.

If one wants to make an ingredient or product truly pareve, the plant equipment must undergo a process of equipment kosherization (see the Section Equipment Kosherization). From a marketing stand point, a pareve designation is most desirable because it has the most uses, both for the kosher and for the nonkosher consumer.

Kosher: Special Foods

Grape Products

To be kosher, all grape juice-based products can only be handled by Sabbath-observing Jews from grape-pressing to

final processing. If the juice is pasteurized (heated or 'mevushal' in Hebrew), then it can be handled by any worker, as an ordinary kosher ingredient. If a liquid bottling line, example, a soda line, uses a product with nonkosher grape juice, the line would have to be cleaned (rinsed) out before proceeding to make kosher products.

Jewish Cheese (Gevinas Yisroel)

Similar to the laws concerning kosher wine production, most kosher supervision organizations require that the supervising religious person (mashgiach) add the coagulating agent, i.e., the agent that makes the cheese form a curd, into the vat to ensure that the cheese is kosher. Any cheese that does not meet this requirement is unacceptable.

If all the ingredients and equipment used during cheese making are kosher, the whey will be kosher as long as the curds and whey have not been heated above 120 F (49 °C) before the whey is drained off. This is true even if a mashgiach has not added the coagulant. Thus, there is much more kosher whey available in the US than kosher cheese. To produce kosher whey, several manufacturers of Swiss cheese, which has one of the most desirable, whitest wheys, have reduced the temperature at which they work the curds in the hot whey. Instead of using the traditional 125–127 F (52–53 °C), they are using a temperature under 120 F (49 °C) to work the curds and to obtain a kosher whey. But there are other challenges to be overcome to make kosher whey. Much of the whey is produced using spray driers, which are among the most difficult pieces of equipment to kosherize.

Another problem deals with whey cream. Any cream, i.e., separated from cheese at above 120 F (49 °C) is subject to the restrictions that come with the cheese and is, therefore, generally not considered kosher. This cream has recently been used to produce butter, which is therefore not considered kosher. Most rabbis had traditionally accepted butter as kosher without supervision as is still the case with milk (but not fortified milk as there is a concern about the source of some of the vitamins, particularly Vitamin A (shark liver)). The transition to requiring kosher supervision of butter has been difficult. More detailed articles on this, and closely related kosher dairy issues, have been published in 2002.

Cholev Yisroel

Some kosher-observant Jews are concerned about possible adulteration of milk with the milk of nonkosher animals, such as mare's milk or camel's milk, and therefore require that the milk be watched from the time of milking. This 'Cholev Yisroel' milk is required by some of the stricter kosher supervision agencies for all dairy ingredients and dairy products. Rabbis who accept non-'Cholev Yisroel' milk in the US do so for two reasons. First, they believe that the laws in the US and many other countries are strong enough to assure that adulteration with other milks does not occur. Second, the nonkosher milks are worth more money than kosher milks, so there is no incentive to add nonkosher milk to the milk of kosher species.

Yashon (Old) and Chodesh (New) Flour

On the second day of Passover, Jews traditionally brought a grain offering to the Temple in Jerusalem. This served to bless all of the flour that was 'growing' or had already been harvested on that day. Such flour has attained the status of 'yashon' (old) flour. All wheat for flour that has not started to grow by the second day of Passover is considered 'chodesh' (new) and should not be used until the next Passover. For all intensive purposes, the grain would have had to have been planted more than 14 days before the second day of Passover to be covered by that Passover, the minimum time assumed necessary for the seeds to germinate. All winter wheat from the Northern Hemisphere is automatically considered yashon. It is more difficult to assure the yashon status of spring wheat, which generally is harvested in August.

Early Fruit

Another kosher law concerning plants is the requirement that tree fruits not be harvested for benefit until the fourth year. This has been particularly problematic with respect to papaya, a tree fruit, i.e., often not kept alive for four years! Discussion and disagreement about the status of papaya remains at this time.

Passover

The Passover holiday occurs in spring and requires observant Jews to avoid eating most products made from five prohibited grains: wheat, rye, oats, barley, and spelt (Hebrew: chometz). Those observing kosher laws can only eat the specially supervised unleavened bread from wheat (Hebrew: matzos) that are prepared especially for the holiday. Once again, some matzos, i.e., schmura ('watched') matzos, are made to a stricter standard with rabbinical inspection beginning in the field. For other Passover matzo the supervision does not start until the wheat is about to be milled into flour. Matzo made from oats and spelt are now available for consumers with allergies.

Special care is taken to assure that the matzo does not have any time or opportunity to 'rise.' In some cases this literally means that products are made in cycles of less than 18 min. In continuous large-scale operations, the equipment is constantly vibrating so that there is no opportunity for the dough to rise.

Why 18 min? Note that the word for 'life' is the two letter Hebrew word 'Chai.' The drinking toast among Jews is 'L'Chaim,' To life. Because the Hebrew alphabet is 'mapped' to numbers (e.g., Aleph = 1, Bet = 2), the word 'Chai' equals the number 18! Thus fermentation, 'life' is considered to require 18 min to occur. Anything made in less than 18 min has not fermented and has, therefore, not violated the prohibitions of Passover.

In the middle ages, the rabbis of Europe also made products derived from corn, rice, legumes, mustard seed, buckwheat, and some other plants (Hebrew: kitnyos) prohibited for Passover. In addition to the actual 'flours' of these materials, many contemporary rabbis also prohibit derivatives such as corn syrup, cornstarch, and cornstarch derivatives such as citric acid. A small number of rabbis permit the oil from kitnyos materials, or liquid kitnyos products and their derivatives such as corn

syrup. The major source of sweeteners and starches used for production of 'sweet' Passover items is either real sugar or potato-derived products such as potato syrup.

Rabbis are concerned with other foodstuffs that are being raised in areas where wheat and other Passover grains are grown. Because of possible cross-contamination some crops such as fennel and fenugreek are also prohibited for Passover.

During the long period of time from early in the Common Era to the enlightenment, the Jewish communities within Christian countries did not have regular contact with Jews living in Muslim countries. The laws governing these two separate Jewish communities began to drift apart. This was also the period in which Christianity was developing and when it over time rejected the mandates of Hebrew scripture.

As a result, today's European, or Ashkenazic Jewish community has significantly different laws and customs from the Sephardic Jewish community, which included Spain, North Africa, and the Middle East. Sephardic custom, which is the default in Israel, includes among other rules, no ban on all or some of the kitnyos materials like rice, a 'beit yosef' meat standard of absolutely no lung adhesions for all animals, and a willingness to use hind-quarter that has been correctly subject to nikkur or deveining, including removal of the siatic nerve.

Passover is a time of large family gatherings but requires two additional sets of dishes specifically for Passover, one meat and one dairy. Overall, 40% of kosher sales for the traditional 'kosher' companies such as Manischewitz, Rokeach, and Kedem occur for the week of Passover. Stores generally begin to make Passover products available to consumers between four and six weeks before Passover. Some stores will rent space temporarily just for their Passover sales. Consumers who regularly use products such as dietary supplements, and nonlife threatening drugs will be concerned about obtaining a version of their favorite and/or required product, i.e., acceptable for Passover. For drugs, the prohibition of chometz is of special concern because many Jews do not want any manner of chometz in their home, including drugs, pet feeds (yes, there are kosher Passover pet foods), and nonfood items such as rubbing alcohol.

The most stringent kosher consumers only eat 'whole' unbroken matzos on the first seven days of Passover, the seven days observed by Jews everywhere including Israel. Thus, any prepared food for those seven days (the Biblically commanded time) may need to be made without the use of any matzo meal or matzo flour, i.e., no gebruckts (no broken matzos, no wetting). However, on the eighth day – which is a rabbinical extension of Passover outside of the land of Israel – these people will also eat products made with less than whole matzos.

It is a challenge to make Passover food products that are tasty and have a decent texture with all the limitations of Passover. The kosher community welcomes the assistance of the food scientist and the food industry to develop more and better Passover products.

The need to assure the absence of all chometz in the home meant that most Jewish homes go through an extensive spring cleaning every year. Historically, this was believed to have had a beneficial effect in protecting Jews from the spread of some diseases.

Kosher: Other Processing Issues

Equipment Kosherization

There are three ways to make equipment kosher or to change its status back to pareve from dairy or meat. Rabbis generally frown on going from meat to dairy or *vice versa*. Most industrial conversions are from dairy to pareve or from treife to one of the categories of kosher. There are a range of process procedures to be considered, depending on the equipment's before production history.

After a plant, or a processing line, has been used to produce kosher pareve products, it can be switched to either kosher dairy or kosher meat without a special equipment kosherization step. It can also subsequently be used for halal production (from pareve or dairy lines, not always from meat lines), and then, finally, for nonkosher products. In many cases, a mashgiach, i.e., the rabbinically approved kosher supervisor, is needed on site for equipment kosherization, so it normally is beneficial to minimize the number of change-overs from one status to another.

The simplest equipment kosherization occurs with equipment that has only been handled cold. This requires a good liquid caustic/soap cleaning, i.e., the type of cleaning done normally in most food plants. Some plants do not normally do a wet clean up between runs, example, a dry powder packing plant or a chocolate line, and these would need to seek specific rabbinical guidance for the change-over. In recent years, allergy concerns have eliminated some of these conversions. Materials such as ceramics, rubber, earthenware, and porcelain cannot be koshered because they are considered not 'capable' of releasing the flavors trapped within them even during the equipment kosherization process. If these materials are found in a processing plant, new materials may be required for production.

Most food processing equipment is operated at cooking temperatures, generally above 120 F (49 °C), the temperature, i.e., rabbinically defined as 'cooking.' However, the exact temperature for 'cooking' depends on the individual rabbi, in that it is the temperature at which he must immediately remove his hand when he puts it into hot water. Recently, through an agreement by the major four mainstream American kosher certifying agencies, which has been accepted by most normative kosher supervision agencies in the US have settled on 120 F (49 °C) as the temperature at which foods are cooked and this figure is used throughout this paper. (See the Section Dealing with Kosher and Halal Supervision Agencies.)

Equipment that has been used with cooked product must be thoroughly cleaned with liquid caustic/soap before being kosherized. The equipment must then be left idle for 24 h, after which it is 'flooded' with boiling water being defined as water between 190 F (88 °C) and 212 F (100 °C), in the presence of a kosher supervisor. The details depend on the equipment being kosherized. In some cases, particularly foodservice establishments, a 'pogem' (bittering agent, oftentimes ammonia) is used in boiling water in lieu of the 24 h wait and followed up with an immersion in boiling clean water. All this special activity, therefore, leads to extra cleaning of food plant equipment.

The principles concerning koshering by hagalah (boiling water) or irui (boiling water poured over a surface) are based on an ancient understanding of the movement of 'taam' (flavor) in and out of solid materials. The concepts of taam and its movement between products are also used to analyze the many possible combinations of kosher meat, kosher dairy, and/or nonkosher products interacting accidentally, i.e., for analysis only 'after the fact' ('b'de-eved') and unintentionally. For real accidents, the rabbis are able to be more lenient than they might be for things that are done intentionally ('l'chatchilla,' i.e., planned ahead of time). In modern times, where kosher supervision in the US is active, i.e., the rabbis are operating with a contractual agreement and ongoing inspections, there is less room to use leniencies. In Europe, where rabbis may only make informal visits to plants and report on their visits to their congregants and the greater Jewish community, the rules with respect to 'after the fact' nullification can sometimes be used more freely – because the rabbi cannot control any changes made in the processing after he has left the plant, i.e., between visits.

In the case of ovens or other equipment that uses 'fire,' or dry heat, kosherization involves heating the metal until it glows. Again, the supervising rabbi is generally present while this process is taking place. In the case of ovens, particularly large commercial ovens, issues related to 'odor/vapors' and 'steam' must also be considered. Sometimes the same oven can be used sequentially for alternating pareve and dairy baking. The details are beyond the scope of this paper and require a sophisticated rabbinical analysis to determine which ovens can be used for more than one status without requiring kosherization.

The procedures that must be followed for equipment kosherization, especially for hot equipment, can be quite extensive and time consuming – so the fewer status conversions, the better. Careful formulating of products and good production planning can minimize the inconvenience. If a conversion is needed, it is often scheduled for early Monday morning, before the production week starts.

However, as part of the process, the rabbis often do a very thorough check of the piping systems, and often find errors in the official plant documents. Thus, these inspections may actually uncover problems that plant management was not aware of.

Jewish Cooking and Jewish Baking

In some cases it is necessary for the rabbis to 'do' the cooking (Bishul Yisroel). Often this means turning on the pilot light. As long as the pilot light remains lit, the rabbi does not have to be present; if it goes out, he must return. With electrical equipment and appliances, it is possible to keep electricity on all the time, using the lowest setting when actual heating is not taking place.

Baking generally requires Jewish participation, Pas Yisroel, i.e., the Jew must start the ovens. In addition, if the owner of the bakery is Jewish, there may be a requirement for 'taking challah,' i.e., a portion of the dough is removed and needs to be specially handled. Again, the details need to be worked out with the supervising rabbi.

Note that a company that has greater than 50% Jewish management or Jewish ownership is subject to stricter rules, example, the taking of challah, and the need to observe the Sabbath and other Jewish holidays. To work with the less strict rules, some owners sell their business to a gentile for the period of concern, some even do this each week. This is a legally binding contract and, in theory, the gentile owner can renege on his or her informal agreement to legally sell what was sold back. On Passover, the need to do this can be more critical: Any chometz in the possession of a Jew during Passover is forever prohibited in a kosher home, i.e., if a 'Jewish' grocery store receives a shipment of bread during Passover, that bread, even if marked as kosher, though obviously nonPassover, can never be used by an observant kosher-observing Jew.

'Toveling' (Immersing Equipment Purchased from a Gentile)

When a Jewish company purchases or takes new or used equipment from gentiles, the equipment must be immersed in a ritual bath ('mikvah') before being equipment kosherized. Equipment made from metal and glass requires a blessing; complex items that contain glass or metal may need to be toveled but may not need a blessing. A mashgiach needs to be present for this activity when commercial equipment is involved. A natural body of water can be used instead of the indoor mikvah, especially with large equipment.

Tithing and Other Israeli Agricultural Laws

In ancient times, products from Israel were subject to special rules concerning tithing for the priests, their helpers, the poor, etc. These are complex laws that only affect products from Israel. The land of Israel is also subject to the Sabbath (sabbatical) years, i.e., crops from certain years cannot be used. These additional requirements challenge kosher consumers in the US who are interested in purchasing and using Israeli products. Sometimes the rabbis in Israel arrange for companies to tithe when the products are destined for sale in Israel, but rarely for exports. The details of this process are beyond the scope of this paper.

Kosher and Allergies

Many consumers use the kosher markings as a guideline to determine whether food products might meet their special needs including allergies. There are, however, limitations that the particularly sensitive allergic consumer needs to keep in mind.

1. When equipment is kosherized – or converted from one status to another the procedure may not yield 100% removal of previous materials run on the equipment. This became an issue some years ago when rabbis discovered that the special procedures being used to convert a dairy chocolate line to a pareve chocolate line led to enough dairy contamination that consumers who were very sensitive to dairy allergens were having problems. These lines are koshered without water: Either a hot oil or 'pareve' chocolate is run through the line in a quantity

sufficient to remove any 'dairy' residual as calculated by the supervising rabbi.

Both Islam and Judaism do not permit practices to occur that will endanger life. As a result, rabbis decided that none of the current religiously acceptable methods for equipment kosherization of chocolate are effective enough from an allergy perspective to move between dairy and pareve production. Therefore, mainstream kosher supervision agencies no longer permit this conversion. Among the problems with plants running both types of chocolate is the possible cross-contamination by powdered milk dust. This would not affect the kosher status of the product but is obviously not acceptable for allergenic concerns.

2. Kosher law does permit certain *ex post facto* (after the fact) errors to be negated. Trace amounts of materials accidentally added to a food can be nullified if the amount of 'offending' material is less than 1/60 by volume under very specific conditions, i.e., truly added by accident. However, some items can never be negated, example, strong flavor compounds or enzymes that make a significant impact on the product even at less than 1/60. In deference to their industrial client company's desire to minimize negative publicity many kosher supervision agencies do *not* announce when they have used this nullification procedure to make a product acceptable. When there is a concern about allergic reactions, however, many rabbis are now more willing to alert the public as soon as possible for health and safety reasons.

Products that might be made in a dairy plant – e.g., pareve substitutes for dairy products and some other liquids like teas and fruit juices – may be produced in plants that have been kosherized, but may not meet a very critical allergy standard. Care in consuming such products is recommended.

3. Labels that say Dairy and Meat Equipment: There are no intentionally added dairy or meat ingredients, but the product is produced on a dairy or meat line without any equipment kosherization. The product is considered to be like pareve with some additional use restrictions in a kosher home as previously explained. Again, the more sensitive the allergy, the more caution in using such products is advised.
4. In a few instances where pareve or dairy products contain small amounts of fish, such as anchovies in Worcestershire sauce, this ingredient *may* be marked as part of the kosher supervision symbol. Many certifications do not specifically mark this if the fish in the initial material is less than 1/60 by volume. Someone who is allergic should always read the ingredient label.
5. At Passover there is some dispute about 'derivatives' of kitnyos materials, the nongrain materials that are also prohibited for Ashkenazic Jews. A few rabbis permit items like corn syrup, soybean oil, peanut oil, and similarly derived materials from these extensions. The 'proteinaeous' part of these materials is generally not used. Consumers with allergies to these items can therefore purchase these special Passover products from supervision agencies that do *not* permit 'kitnyos'derivatives. With respect to 'equipment kosherization': supervising rabbis tend to be very strict about the clean-up of the prohibited grains (wheat, rye, oats, barley, and spelt) so these Passover products come closest to meeting potential allergy concerns; this may not be the case with respect to the products subject to the extended kitnyos prohibitions.

Consumers should not assume that kosher markings ensure the absence of trace amounts of the ingredient to which they are allergic. The kosher mark is a useful first screen, but products should be carefully tested before assuming everything is okay, i.e., the allergic person should eat a small portion of the product, and increase the amount consumed slowly, over time, to assure no adverse reaction. People with allergies should get into the habit of checking lot numbers on products and purchasing stable goods with a single lot number in sufficient quantity to meet anticipated needs within the shelf-life expectations of the goods.

How thoroughly are dairy ingredients kept out of a pareve line? The current standard for kosher may not meet the needs of allergic consumers since the dairy powder dust in the air may be sufficient to cause allergy problems? With the new US allergy regulations, a company might indicate that a product is religiously pareve, but may not be sufficiently devoid of dairy allergens for very allergic consumers.

Special Issues

Science

Gelatin

Important in many food products, gelatin is probably the most controversial of all modern kosher and halal ingredients. Gelatin can be derived from pork skin, beef bones, or beef skin. In recent years, some gelatins from fish skins have also entered the market.

Most currently available gelatins – even if called 'kosher' – are not acceptable to the mainstream US kosher supervision organizations as they may be from pork or from non-religiously slaughtered cattle.

A recent development has been the manufacture of kosher gelatin from the hides of kosher slaughtered cattle.

One finds a wide range of attitudes towards gelatin among the lenient kosher supervision agencies. The most liberal view holds that gelatin, being made from bones and skin, is not being made from a food (flesh). Further, the process used to make the product goes through a stage where the product is so 'unfit' that it is not edible by man or dog, and as such becomes a new entity. Rabbis holding this view may accept pork gelatin. Most water gelatin desserts and yogurts with a generic 'K' follow this ruling.

Other rabbis only permit gelatin from beef bones and hides, and not pork. Still other rabbis only accept 'India dry bones' as a source of beef gelatin. These bones, found naturally in India from the animals that fell and die in the fields, because of the Hindu custom of not killing the cows, are aged for over a year and are 'dry as wood.' Again, *none* of these products is accepted by the 'mainstream' kosher or halal supervisions, and are therefore not accepted by a significant part of the kosher and halal community.

Biotechnology

Rabbinical scholars currently accept products made by simple genetic engineering, example, chymosin (rennin) was accepted by the rabbis about a half a year before it was accepted by the US Food and Drug Administration (FDA). The basis for this decision involves the fact that the gene isolated from a non-kosher source is far below 'visible.' Subsequently, it is copied many times *in vitro* and then eventually injected into a host, i.e., then reproduced many times. Thus, the original source of the 'gene' is essentially totally lost by the time the food product appears. The production conditions in the fermenters must still be kosher or halal, i.e., the ingredients and the fermenter, and any subsequent processing must use kosher or halal equipment and ingredients of the appropriate status. A product produced in a dairy medium, example, extracted from cow's milk, would be dairy. Mainstream rabbis may approve porcine lipase made through biotechnology when it becomes available, if all the other conditions are kosher. The religious leaders have not yet determined the status of more complex genetic manipulations and genetic manipulation of animals; such a discussion is, therefore, premature.

Pet Food

Jews who observe the kosher laws can feed their domestic animals pet food that contains pork or other prohibited meats. They cannot feed their animals products that contain a mixture of milk and kosher meat. On Passover their pet food can contain kitnyos, but not chometz.

Health

Although many people believe that the kosher laws are also considered to be among the laws that were given for people's benefit, this is not the case.

Regulatory

Dealing with Kosher Supervision Agencies

In practical terms the food industry works with kosher and halal supervision agencies to obtain permission to use the supervision agency's trademark symbol on their products. In this way the industry can make claims in the marketplace that are legal and more important, credible to those intentionally purchasing these products, i.e., this is a third party audit system. This potential choice provides a significant potential opportunity.

Kosher supervision is taken on by a company to expand its market opportunities. It is a business investment that, like any other investment, must be examined critically in this era of total quality management, just-in-time production, strategic suppliers, etc.

What criteria should a company use to select a supervision agency? Supervision fees must be taken into account, and the agency's name recognition is a consideration. Other important considerations include: (1) responsiveness in handling paperwork, in providing mashgiachs at the plants as needed on a timely basis, and in doing routine inspections at a defined frequency during the year (anywhere from twice a year to every day (including continuous) depending on the nature of the production; (2) willingness to work with the company on problem solving; (3) ability to clearly explain their kosher or halal standards and their fee structure. And, of course, one should consider (4) if the 'personal' chemistry is right, and (5) if the agency's religious standards meet the company's needs in the marketplace.

One of the hardest issues for the food industry to deal with in their day-to-day kosher activities is the existence of so many different kosher supervision agencies. How does this impact the food companies? How do the Jewish kosher or Muslim halal consumers perceive these different groups? Because there has not been a central ruling authority for many years in either religion, different rabbis follow different traditions with respect to their dietary standards. Some authorities tend to follow the more lenient standards, whereas others follow more stringent standards. The trend in the mainstream kosher community today is towards a more stringent standard because some of the previous leniencies were considered undesirable but were tolerated when fewer alternatives were available.

One can generally divide the kosher supervision agencies into three broad categories. First, there are the large organizations that dominate the supervision of larger food companies, i.e., the Union of Orthodox Jewish Congregations (OU), Manhattan, the Organized Kashrus Laboratories (OK), Brooklyn, the Star-K, Baltimore, the Kof-K, Teaneck, NJ, and the Chicago Rabbinical Council (CRC), all five of which are nationwide and 'mainstream.'

A quick digression to explain the concept of 'normative mainstream kosher supervision': The concept of a normative mainstream US kosher standard is the *de facto* kosher standard in the US. There are numerous trademarked kosher symbols, greater than 1000 at last count (KASHRUS Magazine, October, 2010), used around the world. Some are more lenient than the 'normative' standard, whereas others are stricter. The letter 'K' cannot be trademarked; any person or company can put a 'K' on a product for any reason and so it is highly suspect.

In addition to the national supervision agencies, there are smaller private organizations and many local community organizations that provide equivalent religious standards of supervision. As such, products accepted by any of the normative mainstream organizations will, with an occasional exception, be accepted by other similar organizations.

The second category of kosher supervision (more stringent than normative mainstream) is generally associated with the 'Hassidic' communities, i.e., groups with standards beyond the normative Orthodox standard. Many of the products used in these communities require continuous rabbinical supervision rather than the occasional supervision used by the mainstream organizations for production-line products.

The third level is mainly individual rabbis who are more 'lenient' than the mainstream standard. Many of these rabbis are Orthodox; some may be Conservative. Their standards are based on their interpretation of the kosher laws and are almost always well within traditional standards. Employing a more lenient rabbi means that the food processor cuts out more of the 'mainstream' and stricter markets; this is a retail marketing decision that each company makes for itself. More lenient supervisions are sometimes the only ones that will certify a

product with a special problem that causes other supervisions to reject it.

In recent years we have started to see products that have dual halal and kosher certification. The first were the military MREs (meals ready-to-eat).

Ingredient companies should be particularly careful in selecting a supervision agency. They should try to use a 'mainstream' kosher supervision agency because most kosher or halal food manufacturing companies will require such supervision. The ability to sell to as many customers as possible requires a broadly acceptable standard. Unless an ingredient is acceptable to the mainstream, it is almost impossible to gain the benefit of having a kosher ingredient for sale. Ingredient companies need to pay attention to the status of the kosher product, i.e., a pareve product is preferred over a dairy product because it has broader potential use.

A system of certification letters is used to provide information from the certifying rabbi concerning the products he has approved. To prevent fraud, it is helpful if these letters are renewed every year and dated with both a starting and ending date. Obviously a kosher supervision agency will only 'accept' letters from agencies they find acceptable. That decision to accept another agency depends on two components: the actual kosher standards of the other agency, and an assessment of how well they operate and enforce their supervision. To make this process work better, more agencies are automating this process and computer systems are improving.

There are, of course, periodic 'recalls' of specific products for various kosher defects that would prevent their use. KASHRUS Magazine, or its website (www.kashrusmagazine.com, and www.kashrut.com) try to provide up-to-date listings of products with problems, both of consumer items and industrial ingredients covering all of the different supervision agencies. Sometimes these recalls highlight secular (FDA/USDA) problems with products, i.e., when the kosher status is inconsistent with the ingredients labeling, the problem is sometimes with the ingredients label! Unfortunately few of these are followed up by the responsible government agency.

The kosher symbol of the certifying agency or individual doing the certification may appear on the packaging. In some industrial situations, where kosher and nonkosher (or halal and nonhalal) products are similar, some sort of color-coding of product labels and packages may also be used. Most of these symbols are 'trademarks' that are duly registered.

Three additional notes about kosher markings on products:

1. To ensure that labels are marked properly, it is the responsibility of the food company to show its labels to its certifying agency before printing. This responsibility includes both the agency symbol and the documentation establishing its kosher status, example, dairy or pareve. It is the responsibility of the kosher supervision agency to review these labels carefully.
2. The labels for private label products with specific agency symbols on their labels should not be moved between plants and cannot be used if supervision changes.
3. The Toronto Rabbinical Council (COR) requires that each label have a plant number on it. This prevents the movement of labels between plants of the same company. They are the only agency that currently requires this additional safeguard.

State Regulations

Approximately 20 states, some US counties, and a few cities have laws specifically regulating the claim of 'kosher.' Many of these laws have referred to 'Orthodox Hebrew Practice' or some variant of this term, example, reference to specific Jewish documents. The US Supreme Court has ruled (by accepting the decision of the Second Court of Appeals) that this is a violation of the first amendment to the Constitution.

The newer laws focus specifically on 'consumer right to know issues' and 'truth in labeling.' They avoid having the state define kosher. Rather, the food producer defines its use of terms such as 'kosher' or 'cholev yisroel' and is held by the state to that standard. Religious foods supervisors (or anyone else) providing supervision must then declare the information that a consumer needs to know to make an informed decision.

Animal Welfare

Animal welfare issues with respect to religious slaughter are discussed, along with recommendations for auditable religious slaughter standards, in the American Meat Institute Guidelines that have been developed by Dr. Temple Grandin (Colorado State University). These standards require that religious slaughter preferably be done with the animals in an upright position (for mammals), although a proper upside down pen will be accepted. Shackling and hoisting of mammals is not permitted while the standard shackling line for birds is also permitted for religious slaughter.

Conclusion

The Kosher Dietary Laws define the foods a practicing Jew will eat. This is important for the social well-being and spiritual health of those who follow these laws. In addition, many of the issues addressed by the religious supervision authorities are of value to other consumers in the market place, either as directly affecting their health (e.g., allergen issues), their perception of food (e.g., animal welfare) or their spiritual health (e.g., the perception that religiously supervised products have abstract spiritual benefits). Thus the food industry in providing religiously supervised products not only creates new markets, but also takes on a responsibility that needs to be taken seriously. They also need to be thanked for providing these services.

PREFACE

Why an Encyclopedia on Food Safety?

With the world's growing population, the provision of a safe, nutritious, and wholesome food supply has become a major challenge. To achieve this, effective risk management based on sound science and unbiased information is required by all stakeholders, including the food industry, governments, and consumers themselves. In addition, the globalization of the food supply requires the harmonization of policies and standards based on a common understanding of food safety among authorities in countries around the world.

Furthermore, reports of food safety incidents and foodborne disease outbreaks in one country are disseminated almost instantaneously through the 24/7 news cycle to consumers in other countries all over the world. Consequently, food safety managers in government and industry are sometimes called on to respond to queries from politicians, the media, and the general public even before they may be aware of the problem. Taking effective intervention measures and communicating the basis of their decisions and actions are essential for maintaining confidence in the safety of the food supply.

In all the above circumstances, sound scientific information is the key to effectively and efficiently assess, manage, and communicate on food safety risks. Yet, professionals and other specialists working in this multidisciplinary field are finding it increasingly difficult to keep up with developments outside their immediate areas of expertise. The time and staff needed to provide this information are beyond the resources of most individuals and organizations. Therefore, a single source of concise, reliable, and authoritative information on food safety has, more than ever, become a necessity.

This is the role that the Encyclopedia on Food Safety sought to fulfill by gathering all of the world's knowledge and expertise covering the entire spectrum of food safety topics into one comprehensive reference work. This was done with the objective of facilitating the work of those working in the field of food safety and related fields, such as nutrition, food science and technology, and environment. The Encyclopedia also provides a platform for experts to share their state-of-the art expertise and experience with the rest of the food safety community. Furthermore, the Encyclopedia's online feature is designed for rapid search and retrieval of relevant information.

Who Will Benefit from the Food Safety Encyclopedia?

The Encyclopedia will be useful for professionals and other specialists working in, but not limited to, the following institutions:

- Regulatory and enforcement agencies.
- Food industry.
- Trade and industry organizations.
- Audit and certification bodies.
- Academic institutions.
- Private and governmental scientific and research institutions.
- International and nongovernmental organizations with an interest in food.

What Does the Encyclopedia of Food Safety Contain?

With some 280 articles, the Encyclopedia provides comprehensive coverage a broad range of food safety topics, which may be grouped under the following general categories:

- History and basic sciences that support food safety.
- Foodborne diseases, including surveillance and investigation.
- Foodborne hazards, including microbiological and chemical agents.
- Substances added to food, both directly and indirectly.
- Food technologies, including the latest developments.
- Food commodities, including their potential hazards and controls.
- Food safety management systems, including their elements and the roles of stakeholders.

In developing the Encyclopedia, the editors and members of the Editorial Advisory Board have aimed to ensure that the Encyclopedia provides:

- Contributions by the foremost authorities in their fields.
- Unbiased and concise overviews on a multitude of food safety subjects.
- References for further information
- Specialized and general definitions for food safety terminology.

While the editors have made every effort to ensure that the Encyclopedia reflects the most complete and up-to-date information available, new scientific findings, and advances in food safety occur continuously. In undertaking a project of this scale and with the inevitably delays that occur during production, the editors acknowledge that some topics may have been omitted or insufficiently addressed. Therefore, the feedback of readers to point out any such errors or oversights will be greatly appreciated and will facilitate the development of future editions.

Acknowledgments

The lead editors would like to thank the Editorial Advisory Board members, section editors, and particularly, the authors who have generously contributed their time and talent to the development of this Encyclopedia. We are indebted to the Elsevier secretariat, which has assisted in the production of this work since its inception. Finally, a special note of thanks goes to our families whose patience and support are greatly appreciated.

Ewen Todd Consulting LLC, Okemos, MI, USA

DEDICATION

This Encyclopedia is dedicated to our children, our grandchildren, and all the world's future generations who we hope will enjoy the benefits of a safe and nutritious food supply, produced with fair management of people working in industry and ethical treatment of animals.

FOREWORD I

Today's food system is one of the humanity's great achievements. It includes millions of commercial actors all over the world who produce, process, transport, store, market, and serve food that feeds billions of people daily. The complexity, diversity, and scope of the food system are almost beyond comprehension – ranging from small producers and processors serving local communities to vast global enterprises producing food for millions and managing extended international supply chains – all aimed at meeting high consumer expectations for safe, nutritious, and affordable food.

For all of its successes, the food system is full of challenges. Food insecurity and hunger remain major problems worldwide, and, for those with ready access to the foods of their choice, it is too easy to choose products high in salt, fat, and added sugar. Food safety – the task of avoiding chemical and microbiological contamination of food that can make people sick – is another persistent and dynamic challenge. In fact, new products in the marketplace, new patterns of production and supply, new consumer behaviors and new bacterial and chemical hazards – coupled with high consumer expectations – conspire to make food safety one of the central challenges of today's food system.

People working in the food system know this. Prominent illness outbreaks and contamination incidents take a toll on the public's health and cause a loss of confidence that can steer consumers away from healthy foods, like fresh fruits and vegetables, and impose big economic losses on food producers and processors. And the food system is responding with a heightened awareness of food safety at all levels of the food system and tremendous effort across the system to improve food safety. Much progress is being made.

One of the most important food safety developments of the last quarter century has been the emergence of a widely shared, science-based understanding of foodborne illness, its causes, and how it can be prevented. This begins with the understanding that the current burden of foodborne illness is unacceptable because it is largely preventable. It is preventable if we see food safety as a food system issue and recognize that microbiological and chemical hazards can enter the food supply at any point in the system along the pathway from the farm through processing, transport, storage, and retail sale. Likewise, opportunities to minimize hazards and help prevent food safety problems exist throughout the system, which means that everyone in the system shares responsibility for the safety of the food we eat.

Fulfilling this responsibility requires that we understand as much as we can about food safety hazards and their causes, devise the appropriate, science-based preventive controls for particular hazards and food production settings, monitor their effectiveness, and adjust the controls as needed based on experience. In short, progress on food safety depends fundamentally on a strong base of knowledge and continuous learning to systematically prevent food safety problems. And participants across the global food safety community are actively seeking and applying the knowledge needed to produce safe food and meet high consumer expectations.

This food safety encyclopedia provides a comprehensive overview of what we know about food safety hazards and control measures. We have more to learn, but the knowledge compiled in this encyclopedia demonstrates that we know a lot and that what we know can help empower participants in today's food system to fulfill their food safety responsibility. Although the food safety challenge is global and continuing, and may seem daunting, it can be met if all who share responsibility for food safety take advantage of the knowledge we have, participate in continuous learning, and place first priority every day on protecting the safety of food. That will be good for the food system – and for the consumers it serves.

Michael R Taylor
Deputy Commissioner for Foods and Veterinary Medicine, US Food and Drug Administration (FDA), Silver Spring, MD, USA

FOREWORD II

Food is one of the most basic requirements to sustain life. However, the safety of food and water cannot be taken for granted. Owing to both manmade and natural processes, an array of chemical and microbiological disease-causing agents find their way into food through multiple routes. When contaminated, such food can endanger or even destroy life. Therefore, from time immemorial, humankind has waged a constant battle against foodborne disease. Over many centuries of human development, people invented technologies that helped them fighting this battle, such as cooking, smoking, sun drying, canning, and freezing, to mention but a few. But like any scientific advance, some of these technologies presented their own food safety issues.

In a number of holy books, religious proscriptions for handling food contributed to food safety. In addition, many centuries ago, some governments already recognized that they had responsibilities in this domain and many laws were enacted to ensure the purity of certain foods. But it was only at the end of the nineteenth century, following scientific developments in the field microbiology and other areas of food science, that 'modern' food regulatory activities started.

In 1948, the availability, accessibility, and affordability of food were recognized as a basic human right by the United Nations in its Universal Declaration of Human Rights (Article 25, 1948). Implicit in this concept is the assumption that the food is first and foremost safe to consume, i.e., absence of health damaging properties. It is therefore not surprising that in the same year, the World Health Organization (WHO) was established as a specialized agency of the United Nations with a broad health mandate that included the specific responsibility to "develop, establish and promote international standards with respect to food…". Subsequently in 1963, WHO together with the Food and Agriculture Organization of the United Nations established an intergovernmental body to develop international standards for food – the Codex Alimentarius Commission. Today Codex stands as a major achievement in the promotion of food safety worldwide with an extensive collection of health and safety recommendations for food that are international recognized and referenced by the World Trade Organization and its member countries.

Thirty years ago, in 1983, WHO, again jointly with FAO, convened an Expert Committee on Food Safety to review the global food safety situation and provide guidance for governments, the food industry and consumers on how to cope with the inherent hazards and risks of our food supply. Based on available data and evidence at the time, the committee concluded that "illness due to contaminated food is perhaps the most widespread health problem in the contemporary world and an important cause of reduced economic productivity."

Unfortunately, this rather alarming statement appears to be still true today. Recent studies examining the morbidity and mortality of foodborne diseases have confirmed the significant public health burden posed by these diseases. In developed countries, one-quarter to one-third of the population are made ill each year because of foodborne diseases. In the developing world, the burden is much more severe. For example, diarrheal diseases are now estimated to cause 2.43 million deaths a year. According to WHO statistics, this is the second leading cause of mortality in low-income countries and kills more people than human immunodeficiency virus infection/acquired immunodeficiency syndrome (HIV/AIDS), malaria, or tuberculosis.

In addition, the large number of food safety crises, which occur with increasing frequency, is contributing to the growing public demand for better health protection from contaminated food. This has prompted governments to strengthen their food safety legislation, improve capacities and infrastructure, and tighten control measures. Examples of governmental measures include the creation of European Food Safety Agency by the European Union in 2002, the Food Safety Modernization Act in the USA of 2011 and, most recently, 2013, the commitment of the Premier of the People's Republic of China, Mr. Li Keqiang, to act with an 'iron fist' to improve food safety.

These positive developments are, unfortunately, contrasted by the fact that in many other countries, mostly developing countries, food safety does not receive the attention it deserves. In this regard, the medical profession and public health community appear to be slow in accepting the role that contaminated food plays in the epidemiology of diarrhea, particularly in infants and young children. The treatment of hospitalized cases and outpatients is rarely seen as an opportunity for educating patients and their families on why foodborne diseases occur and how they can be prevented. Two publications published in WHO's Bulletin in 1993 and 2003 urged the health sector to take steps to correct this oversight. Yet even today progress has been disappointing. For example, in the 2009, United Nations Children's Fund (UNICEF) and WHO published a document entitled 'Diarrhea: Why children are still dying and what can be done,' that again overlooked food safety as one of the most important interventions for these diseases. Consequently, in a recent publication in a prestigious *Medical Journal of Gastroenterology*, the issue had to be raised again and omission corrected. It can only be hoped that the public health and donor communities will eventually adopt a more holistic approach for the prevention of diarrheal diseases, which includes essential food safety interventions.

It is for this and many other reasons that I enthusiastically welcome the initiative of Elsevier to publish this Encyclopedia of Food Safety under the editorial leadership of Drs. Yasmine Motarjemi and Gerald Moy (my former WHO colleagues) as well as Dr Ewen Todd, a world renowned expert in food safety. The laudable collaboration and support of the Editorial Advisory Board, Section Coordinators, and the many authors who have freely devoted their time to advance the cause of food safety through the development of this Encyclopedia is also acknowledged.

With such a collection of information, whoever needs first-hand, reliable, and authoritative information on food safety does not need to consult various books, periodicals, or

websites. All of what is presently known in this domain can be found in this comprehensive work. In particular, the Encyclopedia will be useful for decision-makers, managers, officials, and scientists working in government, the food industry, academia, and nongovernmental organizations.

This Encyclopedia may be particularly important for colleagues in developing countries to not only improve food safety for their people but also convince politicians and other policy makers of the pivotal role of food safety in health and development. Without this awareness, the ultimate goal of safe food for all cannot be achieved.

F Käferstein
Former Director, Food Safety and Food Aid Programme (1980–98), World Health Organization, Wiesbaden, Germany

EDITOR-IN-CHIEF

Yasmine Motarjemi holds a Masters degree in Food Science and Technology from the University of Languedoc, Montpellier, France (1978) and a Doctoral degree in Food Engineering from the University of Lund, Sweden (1988).

After her research and academic career at the University of Lund, in 1990, she joined the World Health Organization in Geneva as Senior Scientist. In WHO, she was responsible for the surveillance and prevention of foodborne illnesses (including education of professional food handlers and consumers), the development of the food safety assurance systems (e.g., Hazard Analysis and Critical Control Point system), and for assistance to the WHO Member States in strengthening their national food safety programme. She also contributed to the development of the risk analysis process. She has served in the Secretariat of various sessions of the Codex Alimentarius Commission and its Committees.

From 2000 to 2011, she held the position of Assistant Vice President in Nestlé where she worked as the Corporate Food Safety Manager. In this capacity, she has, among others, developed the Nestlé Food Safety Management system and managed various emerging food safety issues and crises.

She is the author, co-author, or editor of numerous peer-reviewed articles, books, training manuals, and other publications. Her latest books are Food Safety Management: A Practical Guide for the Food Industry (Elsevier 2014) and Invisible Things (original in French under the title: Les Invisibles), a book on food safety for children.

CO-EDITORS BIOGRAPHY

Dr Gerald G Moy, since his retirement from the World Health Organization in 2008, is a scientific adviser with Food Safety Consultants International working with numerous governments and international organizations. His expertise includes assessment of national food safety programs, risk assessment of chemical hazards in food, total diet studies, food safety during mass gatherings, and food defense. Dr Moy is the editor-in-chief for recently published book Total Diet Studies (Springer) and is currently preparing a chapter on food and water protection for a book on key public health considerations during mass gatherings. He serves on the International Scientific Advisory Committee of the China National Center for Food Safety Risk Assessment, the Technical Advisory Group of the World Food Program Technical Advisory Group, and the WHO International Virtual Advisory Group on Mass Gatherings. He is the author of numerous book chapters, articles, and publications and serves on the editorial boards for several food safety journals.

He received his BS in chemistry from the University of Wisconsin and his PhD in physical organic chemistry from Oregon State University, followed by a post-doctoral fellowship in biophysics at the University of New Mexico. He is a Fellow in International Academy of Food Science and Technology and a recipient of the 2009 Great Wall Friendship Award for his contributions to food safety during the Beijing Olympics.

Ewen CD Todd is the President of Ewen Todd Consulting and the former Professor in the Department of Advertising, Public Relations and Retailing, and he is also the Adjunct Professor in the Departments of Food Science and Human Nutrition and Large Animal Clinical Sciences at Michigan State University (MSU). He was former directors of the Food Safety Policy Center and the National Food Safety and Toxicology Center at MSU. At both these centers, Dr. Todd coordinated research in microbiology, toxicology, epidemiology, risk assessment, social science, and policy in the area of food safety, distance education programs, and outreach in the community. Previously, he was in the Bureau of Microbial Hazards, Health Products and Food Branch, Health Canada, Ottawa where he was a research scientist for 33 years working on methods development for pathogens in foods, foodborne disease investigation and reporting, costs and surveillance of disease, illnesses caused by seafood toxins, and risk assessment of foodborne pathogens. He also helped develop risk management strategies for the Department including producing videos and pamphlets on food safety education. Some of his recent research has been working on *Listeria* and *E. coli* O157 transfer coefficient and modeling projects, hygiene in child care centers, schools, and elder care facilities. He has also collaborated with government agencies and academia in Spain, Kuwait, Saudi Arabia, Lebanon, Cambodia, Korea, Japan, and China on food safety issues, and is an expert witness in legal suits involving food safety. He has published extensively on many different aspects of food safety, including 11 recent papers on food workers and hand hygiene. He is active in the International Association for Food Protection (IAFP) and other organizations, and speaks and organizes symposia at national and international meetings. He is the associate editor for the Journal of Food Science and is a frequent reviewer of manuscripts submitted to several different scientific journals.

He has received the Government of Canada Distinctive Service Award for extraordinary teamwork and support to the Science and Technology Community; Recipient of the Excellence in Science Award for 1998 by Health Canada; Deputy Minister's Award of Team Excellence for the work done in promoting the Fight BAC! Campaign in Canada; the Professional Institute of the Public Service of Canada Gold Medal for Pure and Applied Science; and he is Fellow of the American Association for the Advancement of Science, the IAFP, and the MSU University Outreach and Engagement. He is also an honorary life member of the IAFP. He is a graduate of Glasgow University with a BSc in Bacteriology and a PhD in bacterial systematics.

Environmental Contaminants

Toxic Metals

Foods, Materials and Risks

Safety of Food and Beverages

VOLUME 4 Food Safety Management

Food Safety Management

Public Health Measures

Food Safety Assurance Systems

Institutions Involved in Food Safety

HOW TO USE THE ENCYCLOPEDIA

The material in this encyclopedia is organized into five broad sections, presented in four volumes. The sections consist of:

1. **History, science, and methods**: this section includes papers which help in the understanding of basic sciences underpinning food safety and foodborne diseases and their historical development.
2. **Hazards and diseases**: this section addresses the features of major foodborne hazards be they chemical, microbial, parasitical or physical and their health consequence.
3. **Food technologies**: this section explains the various food technologies and aspects related to their safety, or risks in their application.
4. **Foods, materials, and risks**: similarly, in this section, various groups of food products are described in terms of their risks and measures needed to ensure their safety.
5. **Food safety management**: finally, in this part, the building blocks of food safety management in the private and public sector are explained. The role of major international organizations is also reported.

To help realize the full potential of the material in the Encyclopedia the authors have provided five features to help you find the topic of your choice: a preface giving an overview of the encyclopedia and its objectives, a contents list by subject; an alphabetical contents list; cross-references to other articles; and a full subject index.

1 Contents List by Subject

Your first point of reference will probably be the contents list by subject. This list appears at the front of each volume, and groups the entries under subject headings describing the broad themes of quaternary science. This will enable the reader to make quick connections between entries and to locate the entry of interest. Under each main section heading, you will find several subject areas and under each subject area is a list of those entries that covers aspects of that subject, together with the volume and page numbers on which these entries may be found.

2 Alphabetical Contents List

The alphabetical contents list, which also appears at the front of each volume, lists the entries in the alphabetical order. This list provides both the volume number and the page number of each entry. On the opening page of an entry a contents list is provided so that the full details of any articles within the entry are immediately available.

3 Cross-references

All of the entries in the Encyclopedia have been extensively cross-references. The cross-references, which appear at the end of the entry, serve three different functions:

i. To indicate if a topic is discussed in greater detail elsewhere.
ii. To draw the reader's attention to parallel discussions in other entries.
iii. To indicate the material that broadens the discussion.

Example

The following list of cross-references appear at the end of the entry Characteristics of Foodborne Hazard and Diseases | Drug Resistant Pathogens.

> *See also*: Bacteria: *Listeria monocytogenes*; *Salmonella* Non-Typhi; *Salmonella* Typhi and *Salmonella* Paratyphi; Shiga Toxin-Producing *Escherichia coli* and Other Pathogenic *Escherichia coli*; *Shigella*; *Yersinia enterocolitica* and *Yersinia pseudotuberculosis*. Characteristics of Foodborne Hazard and Diseases: Cost of Foodborne Diseases. Food Safety Assurance Systems: Cleaning and Disinfection. Public Health Measures: Food Safety in Hospitals and Other Healthcare Settings; Surveillance of Foodborne Diseases

Here you will find examples of all three functions of the cross-reference list: a topic discussed in greater detail elsewhere (e.g., *Listeria monocytogenes*; *Salmonella* Non-Typhi; *Salmonella* Typhi, and *Salmonella* Paratyphi; Shiga Toxin-Producing *Escherichia coli*), parallel discussion in other entries (e.g., Other Pathogenic *Escherichia coli*), and reference to entries that broaden the discussion (e.g., Food Safety Assurance Systems: Cleaning and Disinfection. Public Health Measures: Food Safety in Hospitals and Other Healthcare Settings).

4 Index

The index provides you with the page number where the material is located. The index entries differentiate between materials that is a whole entry, is part of an entry, or is data presented in a figure or a table. Detailed notes are provided on the opening page of the index.

5 Contributors

A full list of contributors is listed at the beginning of each volume.

GLOSSARY OF SELECTED TERMS

This Glossary of Selected Terms is a partial list of definitions for terms commonly used in the area of food safety. The terms selected are those that are important for communication among the various disciplines or are often subject to misunderstanding. Most of the definitions are taken from those recommended by international organizations or given by the authors contributing to this Encyclopedia. In cases where there are different definitions for a term, the Glossary presents the definition that is most consistent with usage by the majority of authors. Note that in some instances, slight differences between general definitions in this Glossary and those appearing in the individual articles may occur as the result of the specific context of the articles.

Acceptable daily intake The estimate of the amount of a substance in food or drinking water, expressed on a body weight basis, that can be ingested daily over a lifetime without appreciable health risk to the consumer.

Acute reference dose The estimate of the amount of a substance in food or drinking water, expressed on a body mass basis, that can be ingested in a period of 24 h or less without appreciable health risk to the consumer.

Adulteration (economic) A fraudulent action which is intended to omit a valuable constituent or substitute another substance, in whole or in part, for a valuable constituent; conceal damage or inferiority in any manner; or add any substance to increase its bulk or weight, reduce its quality or strength, or make it appear bigger or of greater value than it is (Note that in the US, adulterated food is generally defined as impure, unsafe, or unwholesome food.).

Antiseptic A substance that inhibits the growth and development of microorganisms. For practical purposes, antiseptics are routinely thought of as topical agents, for application to skin, mucous membranes, and inanimate objects, although a formal definition includes agents which are used internally, such as the urinary tract antiseptics.

As low as reasonably achievable A risk management approach that aims to keep exposure to a substance at the lowest level that is realistically achievable.

Asymptomatic shedder A person who does not exhibit the symptoms of an illness but excrete the pathogen (*see also* carrier).

Benchmark Reference point or standard against which performance or achievements can be assessed. A benchmark refers to the performance that has been achieved in the recent past by other comparable organizations, or what can be reasonably inferred to have been achieved in the circumstances.

Biomarkers Indicators of changes or events in human biological systems. Biomarkers of exposure refer to cellular, biochemical, or molecular measures that are obtained from biological media such as human tissues, cells or fluids, and are indicative of exposure to a substance. Biomarkers of effect refer to biological changes that represent an alteration in endogenous body constituents (e.g., depression of cholinesterase levels as an indicator of exposure to pesticides).

Carrier A person or animal that harbors a specific infectious agent without discernible clinical disease and serves as a potential source of infection. The carrier state may exist in an individual with an infection that is unapparent throughout its course (commonly known as healthy or asymptomatic carrier), or during the incubation period, convalescence and postconvalescence of an individual with a clinically recognizable disease (commonly known as an incubatory or convalescent carrier). Under either circumstance the carrier state may be of short or long duration (temporary or transient carrier, or chronic carrier) (*see also* asymptomatic shedder).

Case-fatality rate Usually expressed as the percentage of persons diagnosed as having a specified disease who die as a result of that illness within a given period. This term is most frequently applied to a specific outbreak of acute disease in which all patients have been followed for an adequate period of time to include all attributable deaths. The case-fatality rate must be clearly differentiated from the mortality rate (Compare with mortality rate).

Colony-forming unit A measure of viable bacterial or fungal cells in which a colony represents an aggregate of cells derived from a single progenitor cell.

Contaminant Any biological, chemical, or physical agent not intentionally added to food, which is present in food as a result of the production, manufacture, processing, preparation, transport, or holding of such food (Compare with hazard).

Control (noun) The state wherein correct procedures are being followed and critical criteria are being met.

Control (verb) To take all necessary actions to ensure and maintain compliance with criteria established in the Hazard analysis and critical control point system (HACCP) plan.

Control measure Any action and activity that can be used to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Corrective action Any action to be taken when the results of monitoring at the Critical Control Point (CCP) indicate a loss of control.

Crisis A predicted or unpredicted event which represents an immediate or future significant threat to an organization, its employees, consumers, and the public at large.

Critical control point A step at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Critical limit (CL) A criterion which separates acceptability from unacceptability.

Detergent A chemical used to remove grease, dirt and food, such as washing-up liquid.

Disability adjusted life year (DALY) A metric used to express a health gap that extends the concept of potential years of life lost due to premature death to include equivalent years of 'healthy' life lost by virtue of being in states of poor health or disability. The DALY combines in one measure the time lived with disability and the time lost due to premature mortality. One DALY can be thought of as one lost year of 'healthy' life and the burden of disease as a measurement of

the gap between current health status and an ideal situation where everyone lives into old age free of disease and disability.

Disinfectant A chemical agent or a process that destroys, neutralizes, or inhibits the growth of pathogenic microorganisms (*see also* sanitizer).

Dose–response assessment The determination of the relationship between the magnitude of exposure (dose) to a chemical, biological, or physical agent and the severity and/or frequency of associated adverse health effects (response) in the exposed organism, system, or (sub) population in reaction to the agent.

Endotoxin A toxin present in intact bacterial cells and released when bacteria die or the cells are disrupted. A notable endotoxin is lipopolysaccharide, which is a major constituent of the outer cell membrane of Gram-negative bacteria and can cause toxic effect on lysis of bacteria. The term 'endotoxin' is to be differentiated from 'exotoxin', which is a toxin secreted in the surrounding medium and environment of the bacterial cell.

Enterotoxin A cytotoxin produced by bacteria that is specific for the mucous membrane of the intestine and causes diarrhea and/or vomiting associated with foodborne disease. Many infectious microorganisms produce enterotoxins in the gut, but some are produced external to the host (*see also* exotoxin and endotoxin).

Exotoxin A toxin that is secreted by bacteria. There are many different types of exotoxins. They can be released into the susceptible host (after infection and growth) or into the environment, including food (after contamination and growth). Those released into the intestines are typically heat labile (but some *E. coli* strains can produce both heat labile (HL) and heat stable (HS) toxins). *Clostridium perfringens* produces a HL enterotoxin after completion of sporulation in the host's intestines. *Staphyloccocus aureus* and *Bacillus cereus* enterotoxins produced in food are HS and cause vomiting and diarrhea, whereas toxins of *Clostridium botulinum* toxin, also produced in food, are HL and cause systemic neurological symptoms (*see also* exotoxin and endotoxin).

Epidemic The occurrence in a community or region of a group of illnesses which are similar in nature and clearly in excess of normal expectancy, and derived from a common or from a propagated source (Compare with pandemic).

Equivalence The situation where the application of two different food safety management measures lead to the same, or equivalent, public health outcomes.

Equivalence of sanitary measures (import–export of food) Equivalence is the state wherein sanitary measures applied in an exporting country, though different from the measures applied in an importing country, achieve, as demonstrated by the exporting country, the importing country's appropriate level of sanitary protection.

Exposure assessment The qualitative and/or quantitative evaluation of the likely ingestion of a biological, chemical, or physical agent in food as well as exposures from other sources if relevant.

Fecal–oral route A means of spreading pathogenic microorganisms from feces produced by an infected host to another host, usually via the mouth; for example, contact between contaminated hands or objects and the mouth.

Flow diagram A systematic representation of the sequence of steps or operations used in the production or manufacture of a particular food item.

Food Any substance, whether processed, semiprocessed, or raw, which is intended for human consumption, and includes drink, chewing gum, and any substance which has been used in the manufacture, preparation or treatment of 'food' but does not include cosmetics or tobacco or substances used only as drugs.

Food additive Any substance not normally consumed as a food by itself and not normally used as a typical ingredient of the food, whether or not it has nutritive value, the intentional addition of which to food for a technological (including organoleptic) purpose in the manufacture, processing, preparation, treatment, packing, packaging, transport, or holding of such food results, or may be reasonably expected to result, (directly or indirectly) in it or its byproducts becoming a component of or otherwise affecting the characteristics of such foods.

Food allergy A form of food intolerance in which there is evidence of an abnormal immunological reaction to the food (Compare with food intolerance).

Food establishment Any building or area in which food is handled and the surroundings under the control of the same management.

Food handler Any person who handles, prepares, or serves food, be they domestic food handlers, such as preparing family food, or professional food handlers, such as those working in food service establishments (cooks and waiters), retail stores, supermarkets, etc. (*see also* food worker).

Food hygiene All conditions and measures necessary to ensure the safety and suitability of food at all stages of the food chain.

Food industry The term includes primary manufacturing and processing industry as well as some other establishments involved in the food chain.

Food intolerance A reproducible, unpleasant reaction to a food or food ingredient, including reactions due to immunological effects, biochemical factors, such as enzyme deficiencies and anaphylactic reactions that often include histamine release (Compare with food allergy).

Food poisoning (or acute foodborne intoxication) A disease caused by a toxin or a chemical in food with symptoms usually appearing within 24 h after ingesting the agent. This term is commonly misused as a synonym for foodborne disease, which covers both infections and intoxications.

Food safety Assurance that food will not cause harm to the consumer, when it is prepared and/or eaten according to its intended use (Compare with food suitability and food hygiene).

Food safety hazard A biological, chemical, or physical agent in, or condition* of, food with the potential to cause an adverse health effect (Compare with contaminant). *Refers also to property of a food.

Food safety objective (FSO) The maximum frequency and/or concentration of a hazard in a food at the time of consumption that provides or contributes to the appropriate level of protection (ALOP) (Compare with Performance objective).

Food suitability Assurance that food is acceptable for human consumption according to its intended use (Compare with food safety and food hygiene).
Food worker Individuals who harvest, process, prepare and serve food, i.e., across the whole food chain to retail/foodservice; it is broader than that of a food handler, who typically works in foodservice establishments typically foodservice; however, the two terms are used interchangeably in the literature (*see also* food handler).
Foodborne disease Any disease of an infectious or toxic nature caused by or thought to be caused by consumption of contaminated food, including drink.
Foodborne pathogens Disease-causing microorganisms that are transmitted to humans via foods.
Generally recognized as safe Status of a substance that is generally recognized, among qualified experts, as having been adequately shown to be safe under the conditions of its intended use (used mainly in the USA).
Genomics The study of an organism via decoding the entire genetic sequence of the organism.
Genetic modification A process of altering the genetic makeup of an organism by techniques of modern biotechnology.
Genetically modified organism (GMO) AGMO or genetically engineered organism is an organism whose genetic material has been altered using genetic engineering techniques.
Good animal husbandry practice A system of management controls that need to be adopted at the level of primary producers to ensure production of food of animal origin that is safe for human consumption and acceptable for trade in the world market.
Good hygienic practice A system of management controls that need to be adopted at production, processing, storage, distribution, and preparation to ensure safety and suitability of products of consumption.
Good laboratory practice A system of management controls for laboratories and research organizations to ensure the quality, integrity, consistency, and reliability of results.
HACCP plan A document prepared in accordance with the principles of HACCP to ensure control of hazards which are significant for food safety in the segment of the food chain under consideration (see also HACCP).
Hazard A biological, chemical, or physical agent in, or condition*; of, food with the potential to cause an adverse health effect (Compare with contaminant). *Refers also to a property of a food.
Hazard analysis The process of collecting and evaluating information on hazards and conditions leading to their presence to decide which are significant for food safety and therefore should be addressed in the HACCP plan.
Hazard analysis and critical control point system A preventive system which identifies, evaluates, and controls hazards which are significant for food safety.
Hazard characterization The qualitative and/or quantitative evaluation of the nature of the adverse health effects associated with a biological, chemical, or physical agent which may be present in food. For a chemical agent, a dose–response assessment should be performed. For a biological or physical agent, a dose–response assessment should be performed if the data are obtainable.
Hazard identification The identification of the type and nature of adverse effects that a biological, chemical, or physical agent in food is capable of causing in an exposed population.
Incidence rate The number of new cases of a condition arising in a defined group within a given period or the number of new infections per unit of person–time at risk (Compare with prevalence).
In vitro In an artificial environment outside the living organism.
In vivo Within a living organism.
Lethal dose 50% The dose of a substance that would be expected to kill half of a population of exposed organisms.
Margin of exposure Ratio of the no-observed-adverse-effect level or benchmark dose lower confidence limit for the critical effect to the theoretical, predicted, or estimated exposure dose or concentration.
Maximum residue limit The maximum concentration of residues resulting from the use of a pesticide or veterinary drug that is acceptable in or on a food.
Minimum infective dose The lowest number of microorganisms required to cause an infection in the host.
Monitoring (CCP) The act of conducting a planned sequence of observations or measurements of control parameters to assess whether a CCP is under control.
Monitoring (general) Continuous or repeated observation, measurement and evaluation of health, and/or environmental or technical data for defined purposes, according to prearranged schedules in space and time, using comparable methods for sensing and data collection.
Morbidity rate An expression of the number of illnesses in a population at risk over a given period of time (usually one year).
Mortality rate An expression of the number of deaths in a population at risk over a given period of time (usually one year).
Nanomaterials Materials engineered at the nanoscale to have novel functionality or properties. Such properties will typically, but not exclusively, be demonstrated in the size range 1–100 nm, but this size range should be considered approximate.
Nanoparticles Particles with one or more external dimensions in the range 1–100 nm, but this size range should be considered approximate.
Nanotechnology The manipulation or materials at the nano level.
Notifiable disease A disease that must, by law or by ministerial decree, be reported to a government authority.
Outbreak A group of at least two cases of a single illness that are demonstrated by epidemiological investigation to have a single common exposure or source.
Pandemic Epidemic occurring over a very wide area, crossing international boundaries (often more than one continent) and usually affecting a large number of people.
Pasteurization A process involving heat treatment at a prescribed time–temperature combination to kill vegetative forms of pathogens that may be present, while causing minimal changes in the composition, flavor, and nutritive value of food. However, with advances and the development

of new food technologies, the term is sometimes used for nonthermal technologies leading to the same effect.

Pathogen An organism capable of causing disease.

Pathogenesis The course of a disease from its origin to its manifestation; more specifically it refers to the cellular events and reactions, and other pathologic mechanisms occurring in the development of the disease.

Pathogenicity Ability of a microorganism to cause disease in a host (Compare with virulence).

Performance criterion The effect in frequency and/or concentration of a hazard in a food that must be achieved by the application of one or more control measures to provide or contribute to a performance objective (PO) or an FSO.

Performance objective The maximum frequency and/or concentration of a hazard in a food at a specified step in the food chain before the time of consumption that provides or contributes to an FSO or ALOP, as applicable (Compare with Food Safety Objective).

Pesticide Any substance intended for preventing, destroying, attracting, repelling, or controlling any pest including unwanted species of plants or animals during the production; storage; transport; and distribution and processing of food, agricultural commodities, or animal feeds or which may be administered to animals for the control of ectoparasites. The term includes insecticides, herbicides, fungicides, rodenticides and algicides as well as plant growth regulators, defoliants, desiccants, and agents for thinning fruit or preventing the premature fall of fruit.

Prerequisite program Practices and conditions needed prior to and during the implementation of HACCP and which are essential to food safety.

Prevalence The number of persons in a population who have a disease at a specified point in time or over a specified period of time (Compare with incidence rate).

Primary production Those initial steps in the food chain up to and including, for example, harvesting, slaughter, milking, and fishing.

Processing aid Any substance or material, not including apparatus or utensils, and not consumed as a food ingredient by itself, intentionally used in the processing of raw materials, foods, or its ingredients, to fulfill a certain technological purpose during treatment or processing and which may result in the nonintentional but unavoidable presence of residues or derivatives in the final product.

Processing contaminant Undesirable contaminants that are formed during the treatment of food as a result of the interaction of their natural components or their ingredients.

Provisional maximum tolerable daily intake (PMTDI) The health-based reference value used for contaminants with no cumulative properties. Its value represents permissible human exposure as a result of the natural occurrence of the substance in food and in drinking water. In the case of trace elements that are both essential nutrients and unavoidable constituents of food, a range is expressed, the lower value representing the level of essentiality and the upper value the PMTDI.

Provisional tolerable monthly intake The health-based reference value used for a food contaminant with cumulative properties that has a very long half-life in the human body. Its value represents permissible human monthly exposure to a contaminant unavoidably associated with otherwise wholesome and nutritious foods.

Provisional tolerable weekly intake The health-based reference value used for food contaminants such as heavy metals with cumulative properties. Its value represents permissible human weekly exposure to those contaminants unavoidably associated with the consumption of otherwise wholesome and nutritious foods.

Quality management Quality management includes all the activities that organization use to direct, control, and coordinate quality. These activities include formulating a quality policy and setting quality objectives. They also include quality planning, quality control, quality assurance, and quality improvements.

Recommended dietary allowance The average daily dietary nutrient intake level that is sufficient to meet the nutrient requirements of nearly all (97–98%) healthy subjects in a particular life stage and gender group.

Reservoir An animal species that specifically harbors an infectious agent over long periods, often without harm to the host.

Risk A function of the probability of an adverse health effect and the severity of that effect, consequential to a hazard(s) in food.

Risk analysis A process of decision making (usually government) for managing food safety, consisting of three components: risk assessment, risk management, and risk communication.

Risk assessment A scientifically based process for evaluating risks associated with foodborne hazards, consisting of the following steps: (i) hazard identification, (ii) hazard characterization, (iii) exposure assessment, and (iv) risk characterization.

Risk assessment policy Documented guidelines on the choice of options and associated judgments for their application at appropriate decision points in the risk assessment such that the scientific integrity of the process is maintained.

Risk characterization The qualitative and/or quantitative estimation, including attendant uncertainties, of the probability of occurrence and severity of known or potential adverse health effects in a given population based on hazard identification, hazard characterization, and exposure assessment.

Risk communication The interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors, and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community, and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Risk estimate The quantitative estimation of risk resulting from risk characterization.

Risk management The process, distinct from risk assessment, of weighing policy alternatives, in consultation with all interested parties, considering risk assessment and other factors relevant for the health protection of consumers and for the promotion of fair trade practices, and, if needed, selecting appropriate prevention and control options.

Risk manager A person or an organization (usually government) with the authority to decide on the acceptability of risk and, if necessary, measures needed for their management.

Risk profile The description of the food safety problem and its context.

Safe (food) A level of risk that is deemed to be acceptable by some standard. The question of safety always involves the question of to whom the risk is acceptable, and by what criteria that party judges it so.

Sanitizer Type of antimicrobial (disinfectant) that kills or irreversibly inactivates microorganisms present on a surface, especially designed for use on food-processing equipment. The US Environmental Protection Agency further defines a sanitizer as providing at least 99.9% reductions of all microorganisms on a surface (*see also* disinfectant).

Shelf-life The predicted time at which a product will change from acceptable to unacceptable quality. It is influenced by factors such as raw ingredient quality, processing conditions, packaging practices, and storage conditions. Typically, shelf-life is determined by a combination of microbial, sensory, and chemical methods. 'Shelf-life' can be expressed on food labels by a variety of dates, including 'expiry', 'use by', 'sell by', 'best before', and 'consume by', depending on the applicable legislation.

Step (HACCP) A point, procedure, operation, or stage in the food chain including raw materials, from primary production to final consumption.

Strain An isolate of the same type of microorganism possessing different properties.

Surveillance The systematic, ongoing collection, collation, and analysis of data on specific diseases in a defined population, to guide public health decisions.

Surveillance (active) Public health surveillance that regularly reaches out to diagnostic laboratories or to clinicians to actively collect reports of specific diagnoses of infections.

Surveillance (passive) Public health surveillance that collects reports of specific diagnoses from clinicians or diagnostic laboratories, which they are required or requested to submit because of notifiable diseases regulations.

Time–temperature abuse A situation where food has not been cooked for long enough or at a sufficient high temperature to reduce contaminants to safe levels, or food has been stored for a time or at a temperature that permits bacteria to proliferate.

Traceability/product tracing The ability to follow, forward as well as backward, the movement of a food through specified stage(s) of production, processing, and distribution.

Uncertainty In risk assessment, imperfect knowledge concerning the present or future state of an organism, system, or (sub) population under consideration.

Validation (analytical methods) Practice undertaken to substantiate or confirm methods or procedures perform as expected and in a reliable manner and consistently meet expectations.

Validation (control measures) Obtaining evidence that a control measure or combination of control measures, if properly implemented, is capable of controlling the hazard to a specified outcome.

Validation (HACCP) Obtaining evidence that the elements of the HACCP plan are effective.

Variability Heterogeneity of values over time, space, or different members of a population. Variability implies real differences among members of that population.

Verification (general) The application of methods, procedures, tests, and other evaluations, in addition to monitoring and to determine whether a control measure is or has been operating as intended.

Verification (HACCP) The application of methods, procedures, tests, and other evaluations, in addition to monitoring and to determine compliance with the HACCP plan.

Veterinary drug Any substance applied or administered to any food-producing animal, such as meat or milk producing animals, poultry, fish, or bees, whether used for therapeutic, prophylactic, or diagnostic purposes, or for modification of physiological functions or behavior.

Virulence The degree of pathogenicity of a microorganism as indicated by case-fatality rates and/or its ability to invade the tissues of the host; the competence of any infectious agent to produce pathologic effects. The virulence of a microorganism is a measure of the severity of the disease it causes (Compare with pathogenicity).

Waterborne disease A disease resulting from the contamination of water either by pathogenic viruses, bacteria or protozoa, or by chemical substances. These agents are directly transmitted to people when the water is used for drinking, preparing food, recreation, or other domestic purposes.

Withdrawal period (veterinary drugs) The interval between the time of the last administration of a veterinary drug and the time of the collection of edible tissue or products from a treated animal that ensures the concentration of residues in food comply with the maximum residue limit for the drug.

Zoonosis A disease that can be passed directly or indirectly from animals, whether wild or domesticated, to humans. Also called zoonotic disease.

ABBREVIATIONS OF TECHNICAL TERMS

This is a nonexhaustive list of commonly used abbreviations in the area of food safety.

ADI	Acceptable daily intake.
ADME	Absorption, distribution, metabolism, and excretion.
AI	Adequate intake.
ALARA	As low as reasonably achievable.
ALOP	Appropriate level of protection.
ARfD	Acute reference dose.
BMD	Benchmark dose.
BMDL	Benchmark dose at lower confidence limit.
CCP	Critical control point.
CFR	Case fatality rate.
CFU	Colony forming unit.
CIP	Cleaning in place.
DALY	Disability adjusted life year.
DGGE	Denaturing gradient gel electrophoresis.
DNA	Deoxyribonucleic acid.
EAR	Estimated average requirement.
ED_{50}	Effective dose 50%.
ELISA	Enzyme linked immunosorbent assay.
EMRL	Extraneous maximum residue limit.
FSO	Food safety objective.
GAHP	Good animal husbandry practice.
GAP	Good agricultural practice.
GHP	Good hygienic practice.
GAqP	Good aquacultural practice.
GC	Gas chromatography.
GC–MS	Gas chromatography–mass spectrometry.
GHP	Good hygienic practice.
GLP	Good laboratory practice.
GM	Genetically modified.
GMO	Genetically modified organism.
GMP	Good manufacturing practice.
GPVD	Good practice in the use of veterinary drugs.
GRAS	Generally recognized as safe.
HAB	Harmful algal bloom.
HACCP	Hazard analysis and critical control point.
HPLC	High performance liquid chromatography.
HPLC–MS	High performance liquid chromatography–mass spectrometry.
HPP	High pressure processing.
HTST	High temperature short time.
HUS	Hemolytic uremic syndrome.
IEDI	International estimated daily intake.
IESTI	International estimated short term Intake.
LD_{50}	Lethal dose 50%.
LOAEL	Lowest observed adverse effect level.
LOD	Limit of detection.
LOQ	Limit of quantitation.
MFFB	Moisture on a fat free bases.
ML	Maximum level.
MLST	Multilocus sequence typing.
MLVA	Multiple locus variable number tandem repeat analysis.
MOE	Margin of exposure.
MRL	Maximum residue limit.
mRNA	Messenger ribonucleic acid.
MS	Mass spectrometry.
NEDI	National estimated daily intake.
NOAEL	No observed adverse effect level.
NOEL	No observed effect level.
OPRP	Operational prerequisite programme.
PC	Performance criterion.
PCR	Polymerase chain reaction.
PDCA	Plan do check act.
PEF	Pulsed electric fields.
PFGE	Pulsed field gel electrophoresis.
PMTDI	Provisional maximum tolerable daily intake.
PO	Performance objective.
PRP	Prerequisite program.
PrP	Protease resistant protein.
PTMI	Provisional tolerable monthly intake.
PTWI	Provisional tolerable weekly intake.
QPS	Qualified presumption of safety.
RDA	Recommended dietary allowance.
RNA	Ribonucleic acid.
SMEs	Small- and medium-sized enterprises.
SOP	Standard operating procedure.
SPS Agreement	Agreement on the Application of Sanitary and Phytosanitary Measures.
TBT Agreement	Agreement on Technical Barriers to Trade.
TDI	Tolerable daily intake.
TDS	Total diet study.
TEF	Toxic equivalency factor.
TEQ	Toxic equivalence.
TMDI	Theoretical maximum daily intake.
TSE	Transmissible spongiform encephalopathy.
UHT	Ultra high temperature.
UL	Upper limit.
UV	Ultra violet.

PUBLIC HEALTH MEASURES

Modern Approach to Food Safety Management: An Overview

Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland

Glossary

As low as reasonably achievable (ALARA) A risk management approach that aims to keep exposure to a substance at the lowest level that is realistically achievable.

Food Any substance, whether processed, semi-processed, or raw, which is intended for human consumption; it includes drink, chewing gum, and any substance which has been used in the manufacture, preparation, or treatment of 'food', but does not include cosmetics, tobacco, or substances used only as drugs. (In the context of this topic, drinking water is considered as food).

Foodborne disease Any disease caused by infectious or toxic agent thought to be transmitted by consumption of food (including drinking water); often wrongly referred to as food poisoning.

Food hygiene All conditions and measures necessary to ensure the safety and suitability of food at all stages of the food chain.

Food industry The term includes primary, manufacturing, and processing industry as well as some other establishments involved in the food chain, for example, large-scale catering establishments and retailers.

Food safety Assurance that food will not cause harm to the consumer when it is prepared and/or eaten according to its intended use.

Food safety objective (FSO) The maximum frequency and/or concentration of a hazard in a food at the time of consumption that provides or contributes to the appropriate level of protection.

Food suitability Assurance that food is acceptable for human consumption according to its intended use.

Hazard analysis and critical control point system (HACCP) A system which identifies, evaluates, and controls hazards which are significant for food safety.

Performance criterion The effect in frequency and/or concentration of a hazard in a food that must be achieved by the application of one or more control measures to provide or contribute to a performance objective or an FSO.

Performance objective (PO) The maximum frequency and/or concentration of a hazard in a food at a specified

step in the food chain before the time of consumption that provides or contributes to an food safety objective or appropriate level of protection, as applicable (compare with food safety objective).

Precautionary principle A notion which supports taking protective action before there is complete scientific proof of a risk; that is, action should not be delayed simply because full scientific information is lacking.

Risk A function of the probability of an adverse health effect and the severity of that effect, consequential to (a) hazard(s) in food.

Risk analysis A process consisting of three components: risk assessment, risk management, and risk communication.

Risk assessment A scientifically based process consisting of the following steps: (1) hazard identification, (2) hazard characterization, (3) exposure assessment, and (4) risk characterization.

Risk communication The interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors, and risk perceptions among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Risk management The process, distinct from risk assessment, of weighing policy alternatives, in consultation with all interested parties, considering risk assessment and other factors relevant for the protection of consumers' health and for the promotion of fair trade practices, and, if needed, selecting appropriate prevention and control options.

Verification (general) The application of methods, procedures, tests and other evaluations, in addition to monitoring, to determine whether a control measure is or has been operating as intended.

Introduction – Historical Background

Although protecting food from spoilage and degradation has been a concern for mankind since the dawn of history, it is mainly in the past few decades that food safety management has received its due scientific attention.

The history of food safety goes back to the time of the earliest humans when the consumption of poisonous foods was a threat to their survival. Presumably, they used their sensory perceptions, i.e., taste and smell, together with memory to evaluate the safety of their food. In other words, consumers would directly taste the food and would learn through trial and error, avoiding those foods which presented an acute risk for health. The cold climate during the ice age period also contributed to the preservation of food and the prevention of microbial organisms. Later, the discovery of fire was a major milestone in the history of food safety, as cooking of food, particularly meat, over fire contributed to its nutritional quality and microbial safety. Today, we know that it may also have introduced some process contaminants such as polycyclic aromatic hydrocarbons, acrylamide, food safety concerns discovered in modern times.

As civilization progressed, religious beliefs in many cultures prescribed food handling practices, many with food safety implications. As societies grew to include specialized food-related groups, like the butcher, the baker, and wine maker, governments regulated certain practices and their enforcement set the basis for food safety management. For the most part, these regulatory requirements were focused on the prevention and control of fraud.

The work of several scientists has been instrumental to the progress in the microbial food safety. Among these, Anton von Leeuwenhoek (1632–1723) first reported seeing microbes under the microscope and called these as *animalcules*. Later in the nineteenth century, the work of scientists such as Louis Pasteur (1822–95) who developed the germ theory and Robert Koch known for the criteria which establish the causal relationship between a pathogen and an illness, set the basis of modern food microbiology and food hygiene.

However, until recent history, i.e., the 1970s, unsanitary practices such as the use of unsafe water were the main concern as many prevalent infectious diseases, for example, cholera, shigellosis, typhoid fever, were attributed to the use of unsafe water or poor sanitation. The management of food establishments was also heavily based on visual inspection, and sometimes on subjective judgments. As laboratory techniques developed, microbiological or chemical testing of food products came to complement the visual inspection and formed the basis for food safety management.

In the 1960s, awareness on the chemical aspects of food safety grew from the concern associated with the increasing use of food additives in the food manufacturing industry as well as the use of agrochemicals in the food production. Advocates such as Rachel Carlson, author of the famous book 'Silent Spring' drew the attention of the general public on the environmental risks associated with the use of dichlorodiphenyltrichloroethane, greatly contributed to this awareness.

On the microbiological side, it was only in the mid 1980s that the concern for food safety came to the focus of public health authorities and the decade of 1990s was a period of growing awareness about foodborne illnesses. In countries monitoring foodborne diseases and outbreaks, authorities noted an increase in a number of foodborne diseases such as salmonellosis, campylobacteriosis, and the occurrence of large-scale foodborne disease outbreaks. These, together with the emergence of new pathogenic agents such as enterohemorrhagic *Escherichia coli*, *Campylobacter* spp, *Listeria monocytogenes*, abnormal prions (agent of bovine spongiform encephalopathy (BSE)), and an array of food safety incidents, such as the case of feed contaminated with dioxin in Belgium in 1999, just to mention one as an example, increased consumers' concern and undermined their trust in the safety of the food supply and the capability of regulatory authorities in their governance role. With regard to the developing countries, the role of food

contamination in infant diarrhea and its association with malnutrition received increasing recognition at the international level; however, it was the cholera epidemic in Latin America and Africa in the 1990s, which really raised the awareness of the governments of the developing countries on the importance of food safety management as countries who were affected by cholera saw their food export embargoed for food safety reasons. Later, the European Union extended their food import embargo to all those countries that could not demonstrate capabilities in controlling the safety of their food supply.

Consequent to the increased awareness of the general public on the existence of gaps in food safety management, which were particularly notorious in the management of the BSE crisis in 1996 and 2000 and the dioxin crisis in 1999 in Belgium, a general atmosphere of mistrust developed in Europe. This also affected the acceptance of technologies in food production and processing, for example, the use of food additives, biotechnology, food irradiation, etc. On the other side of the Atlantic in North America and also in other countries like Japan, large scale outbreaks of foodborne diseases associated with foodborne pathogens such as Salmonella, enterohemorrghic *E.coli, Listeria monocytogenes*, alerted the general public on the importance of food safety and a number of programmes for its improvement were initiated (e.g., the Clinton Initiative).

Concomitantly with the increased public concern, the finalization of the Uruguay Round of Multilateral Negotiations in Marrakesh and the establishment of the World Trade Organization (WTO) in 1995 paved the way for increased trade in food and feed, and thus for concern about the import of contaminated food and feed. To provide countries with the right for protection without establishing unnecessary discriminatory regulations, 2 WTO agreements, 'Agreement on the Application of Sanitary and Phytosanitary Measures (SPS)' and the 'Agreement on Technical Barrier to Trade,'" came into force when WTO was established. These agreements also included concepts such as appropriate level of health protection, risk assessment, equivalence, etc, which would require further clarification.

It was in this climate of food safety problems, increased trade in food and feed and increased consciousness about the role of food safety in public health, that a number of fundamental questions were raised among stakeholders:

- How safe should food be?
- What should the Appropriate Level of Protection be?
- To what level should hazards in food be controlled?
- Who decides and what data should be considered in the decision-making process?
- How are consistency, objectivity, acceptability, and efficiency ensured?
- How efficient and cost-effective is a control measure and at what point of the food chain should a hazard be controlled and at what cost?
- How are feasibilities and other risks or factors considered in the decisions?
- How will food safety be controlled in the global market?

Meanwhile, consumers raised a number of questions from their perspective:

- Who is deciding? On what basis?
- How is the uncertainty considered in the decision-making processes?
- How are stakeholders' views taken into account?
- How are the societal values considered?

These questions give rise to principles and concepts such as transparency, precautionary principles, involvement of stakeholders in the decision-making process, and the balance between scientific and social values.

The food safety incidents such as BSE and dioxin mentioned above also raised the importance of:

- The 'Farm to Fork' approach,
- The consideration of science and uncertainty in science in the process,
- Transparency in decision-making,
- The impact of perception on the food supply,
- Defining responsibilities.

The WTO/SPS Agreements already answered a number of questions and contributed to the development of the modern approach to food safety management; required that regulations follow a certain number of principles, namely:

- Be based on sound scientific assessment of the risk,
- Be non-discriminatory,
- Be transparent, and
- Accept equivalent approaches to achieve the same level of health protection.

Additionally, WTO referred to the standards, practices and other recommendations of the Codex Alimentarius Commission (CAC) as the representing international consensus regarding health and safety requirements for food. In other words, the SPS Agreement recognized CAC as a reference for international requirements for food safety. This meant that countries that rejected food which complied with the Codex food safety standards had to provide scientific evidence that the food in question posed a specific risk for their population. Indirectly, this article also encouraged countries to align their legislation with the standards of Codex Alimentarius. Short of this, they could be challenged by an exporting country to provide scientific evidence, i.e., risk assessment, for having a legislation that is more stringent than the standards and recommendations of Codex. A illustrative example of the application of this article was the case of hormones in beef for which European countries had to provide evidence of risk before a WTO Dispute Settlement Panel. Eventually they lost the case based on the risk assessment evidence provided in part by experts serving on the Joint FAO/WHO Expert Committee on Food Additives (JECFA). In this regard, note that Codex bases all of its health standards on the recommendations of JECFA and other FAO/WHO expert bodies.

These developments at the international level and the increased awareness of the general public led to numerous changes in the management of food safety. In the food industry, the application of hazard analysis and critical control point (HACCP) system and traceability received heightened attention and in some countries, it became mandatory. At the

governmental level, risk analysis emerged as a decision-making process. In some countries or regions, it led to the restructuring of governmental institutions. For instance, in Europe, the European Food Safety Authority was established in 2002 as a result.

Concept of Food Safety and its Definition

Today, the subject food safety has become a discipline in its own right and a formal definition was elaborated in 1997 by the CAC.

According to the CAC, 'food safety is the assurance that food will not cause harm to the consumer when it is prepared and/or eaten according to its intended use.'

This definition embodies several important notions:

1) The notion of harm which separates safety aspects of food from other quality aspects that make food unfit for human consumption without necessarily presenting a danger to health. The aspects of food which make it unfit for human consumption, even though it is safe, are referred to by CAC as food suitability.
2) The concept of assurance, i.e., food safety and its management should be based on measures that are in place to provide assurance that food is safe. In other words, food safety depends on the conditions in which food is produced and prepared, and not on the results of the end-product testing, which for many contaminants cannot be a reliable method for food safety assurance. The conditions for ensuring both safety and suitability are referred by the CAC as 'food hygiene.'
3) Preparation and/or use of a food product should be considered in the design of the safety, and *vice versa*. A food product is considered safe if it is prepared and/or used according to its intended use. Subsequently, the intended use should be considered by the producer, manufacturer or, those selling the product in the design of the product as well as in their information to their customers, if necessary. Customers must also follow the instruction of manufacturers. In this way, the definition promotes interaction between the stakeholders of the food chain.

The definition also stipulates that food will not cause harm. However, it is also generally recognized that 100% safety does not exist as, realistically, foods cannot be totally void of the presence of the multitude of hazards in the environment. Even for agrochemical and food additives that undergo extensive testing before they are permitted in food, there is always a chance that toxic effects can occur. This brings in the notion of risk that is also defined by CAC as a function of (a) the probability of an adverse health effect and (b) the severity of that effect, consequential to a hazard(s) in food. Over and above the exposure, the risk depends also on three factors: the susceptibility of the individual, the nature of the agent, i.e., the degree of pathogenicity and virulence (e.g., the dose-response relation, bioavailability of an agent), and also the food matrix. The dose-response relationship for certain pathogens may be different according to the food matrix. For instance, it has been experienced that in a fatty matrix such as chocolate, a lower number of pathogens can trigger illness than in some other foods.

As one tries to analyze the notion of safety, one can see that safety is a complex subject, and often very difficult to communicate. A frequent misconception and error by the general public is not realizing the difference between hazard and risk, i.e., the mere presence of a hazard at a certain low level does not necessarily mean that food is unsafe. It is the quantity of the hazard in the food and the amount of food ingested, in other words the likely dose of exposure, which determines the risk posed by a product.

On a scientific basis, risk assessors can qualitatively and quantitatively evaluate the risks associated with the presence of a given hazard in foods. However, the question remains as to when a food is considered as safe. Today, it is generally accepted that a food is safe when it does not present an unacceptable risk for the population. At the same time, it is recognized that what is considered as an unacceptable risk in a society depends on the perception of the risk by the population, and on a number of other factors such as the cultural and societal values (e.g., animal welfare, religion, and ethics), other health risks such as (nutritional, microbial, or chemical), other societal risks (e.g., environment, reputation), feasibility and costs (which itself impacts on the price of food), consumer preferences (organoleptic quality of food).

Risk communication experts have identified a number of factors that can influence the acceptability of risk. These are:

- The prospects of significant benefit for 'me',
- Whether the risk is voluntary (i.e., if there is consent) or involuntary,
- If the risk is familiar,
- The 'dread' factor
- If the risk and benefit are 'fairly' distributed,
- If the risk is part of an unethical activity,
- If the risk assessor and risk manager are trustworthy,
- Unnatural versus natural risk.

The consideration of these factors is essential in risk management: i.e.,

- Who is assessing the risk,
- How it is carried out,
- Who, how, and what is communicated,
- Which factors are considered in the decision-making process.

These considerations led to a change in the process of decision-making and the introduction of the risk analysis process in food safety management.

Food Safety Management: Shared Responsibility

One of the key functions in the management of any subject is the determination of responsibilities. For the management of food safety at the societal level, in the 1990s the WHO coined the concept of shared responsibility (Figure 1), according to which a concerted effort of the different sectors, i.e., government, industry, consumer, and academia, was needed to ensure that food up to the point of consumption is safe, wholesome, and benefits consumers nutritiously. The concept was represented as a building (temple) where each sector formed a supporting

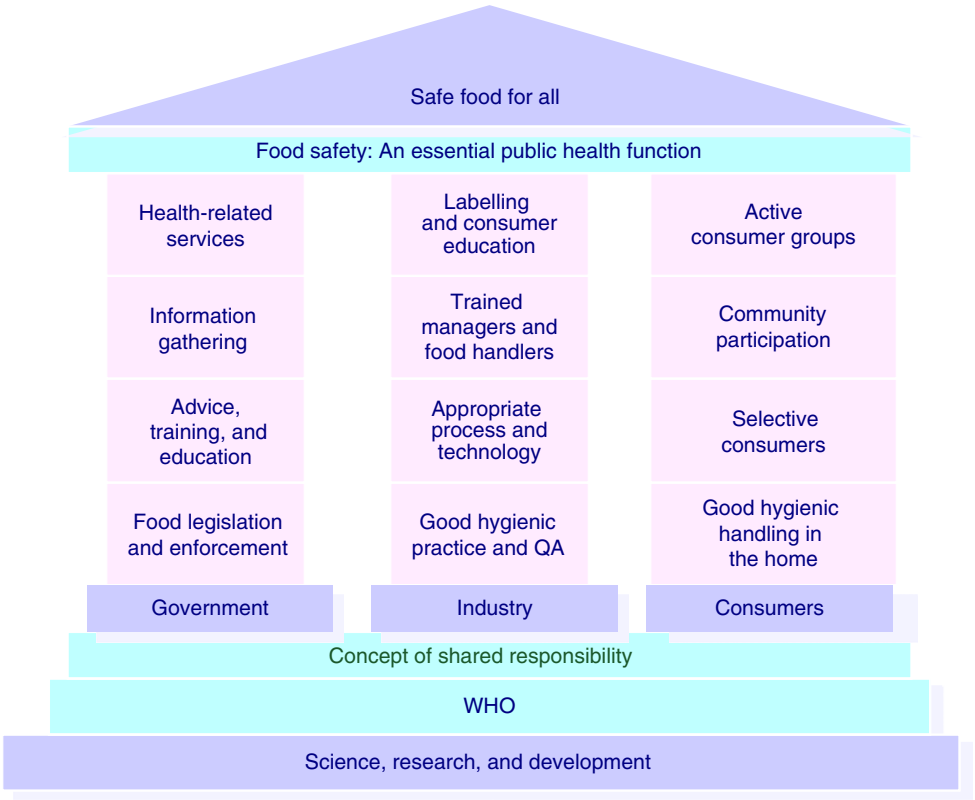

Figure 1 Concept of shared responsibility as proposed by the World Health Organization (WHO). Reproduced from WHO (2000) *Foodborne Diseases: A Focus on Health Education*. Geneva: World Health Organization.

pillar. The building blocks of the pillars describe the roles and functions of each sector. While the building block of the temple has greatly evolved subsequently, the concept as such is still valid.

Principles of Food Safety Management

The developments and events of the 1990s led to a rethink of the principles and procedures of food safety management, both at the national and international level.

The fundamental principle in the new approach to food safety management was the recognition that protection of human health should be the primary objective in food safety management.

Additionally, the following key principles gained prominence:

1. Integrated approach, i.e., consideration of the risks and control measures along the entire food chain up to the point of consumption.
2. Shared responsibility, which as mentioned above, is the recognition that all sectors, including consumers, have a responsibility in ensuring food safety.
3. Multi-disciplinary approach, which comes from the understanding that ensuring food safety requires different types of scientific and operational expertise.
4. Evidence-based and risk-based decision-making to ensure objectivity and the most efficient use of resources in food safety management. This principle is important to assure stakeholders or trading partners that measures are based on scientific and technical evidence, are effective and commensurate to the degree of risk. The principle also facilitates the implementation of the WTO/SPS article on equivalence mentioned below.
5. Equivalence: This principle allows countries to deviate from the requirements of importing countries, if they can demonstrate the equivalence of measures on a scientific basis. This principle was an additional impetus for the concept of validation of control measures.
6. Transparency, uncertainty, and precautionary principles: Transparency is an obvious consequence of the above-mentioned principles on the evidence-based decision-making process. However, it gains particular importance when there is uncertainty in data or when data are lacking. The value of transparency is that, in absence of full scientific information or variation in the degree of risk, the uncertainty and variability are declared; evidence of the adequacy of protective measures is provided. Transparency also increases trust in stakeholders and trading partners. The precautionary principle stipulates the need for taking protective action before there is complete scientific proof a risk that is action should not be delayed simply because full scientific information is lacking.
7. Structured approach: i.e., while risk managers and risk assessors should maintain an active interaction, there should be a functional separation between risk assessment and risk management to ensure objective and unbiased

decision-making, balancing scientific consideration with societal values and economic interests, as well as considering the risk perception of consumers.

8. Harmonization of food standards, although a goal of the CAC, de facto has become a consequence of the WTO/SPS agreement.
9. Continuous improvement: As in any quality management system, a plan, act, and review process should be applied in food safety management in order to incrementally but continuously improve the safety of foods to reduce risks to as low as technically achievable. This principle does not apply to foods which present an immediate and/or an unacceptable risk to consumers' health and where a crisis management procedure should be implemented. The principle applies both in governmental functions that should progressively drive the contamination of food supply and the incidence of illnesses to as low a level as technically and reasonably achievable (as low as reasonably achievable principle), as well as to industry where it is expected to have a yearly objective for improving the food safety assurance system.

Most importantly, there was the recognition that food safety cannot be solely measured by the number of incidents or the end-product testing but should be evaluated in terms of measures put in place to prevent contamination. With regard to the former it should be remembered that a past record of safety is not a guarantee for the future. As to end-product testing this presents several limitations in providing food safety assurance with regard to microbiological hazards:

- End-product testing is of limited value for assessing and verifying safety due to the large number of samples that would be required to be tested to have a reliable evaluation.
- As alluded before, to have a reliable information, a great number of samples need to be tested and this will be costly and thus often not feasible.
- Even if the agent is detected, the approach leads to loss of time and product. In some conditions, for example, in the airline catering business, the food may even be consumed by the time the result becomes available.
- Finally the method leads to the detection of the problem without any information as to its cause.
- With this principle, the limitation of end-product testing as a control measure, in particular for certain hazards such as microbial hazards or mycotoxins, was recognized.

With the trend to move away from end-product testing and statistics on incidence as evidence of safety, emphasis is put on preventive measures and a clear differentiation is made between preventive and control measures versus measures for verification purposes.

Elements of Food Safety Management

Management of food safety in today's world has become a very complex and intricate task. On the one hand, a mind-boggling number of chemical, microbiological, and physical hazards may find their way into the food supply, and this at any stage of the food chain. The control of these *per se* is a major challenge, as each presents a different set of characteristics. On the other hand, measures necessary for ensuring food safety are often intertwined with a number of other considerations of social, environmental, cultural, and economical nature. Awareness of this complexity combined with a number of major food safety crises which hit the society in the past few decades have been an impetus for major changes in the management of food safety and the development of procedures and infrastructure. Parallel to the development of food safety management systems, the food defense system has also been strengthened. The food defense system has been developed with the specific objective to protect food safety from bioterrorism and other types of sabotage.

Figure 2(a) and **(b)** illustrate the functions of different sectors as described below.

Government

Public health and food control authorities have the leading role in managing food safety and have the responsibility of overseeing that food supply is safe up to the point of consumption. With this responsibility, they have to do the following:

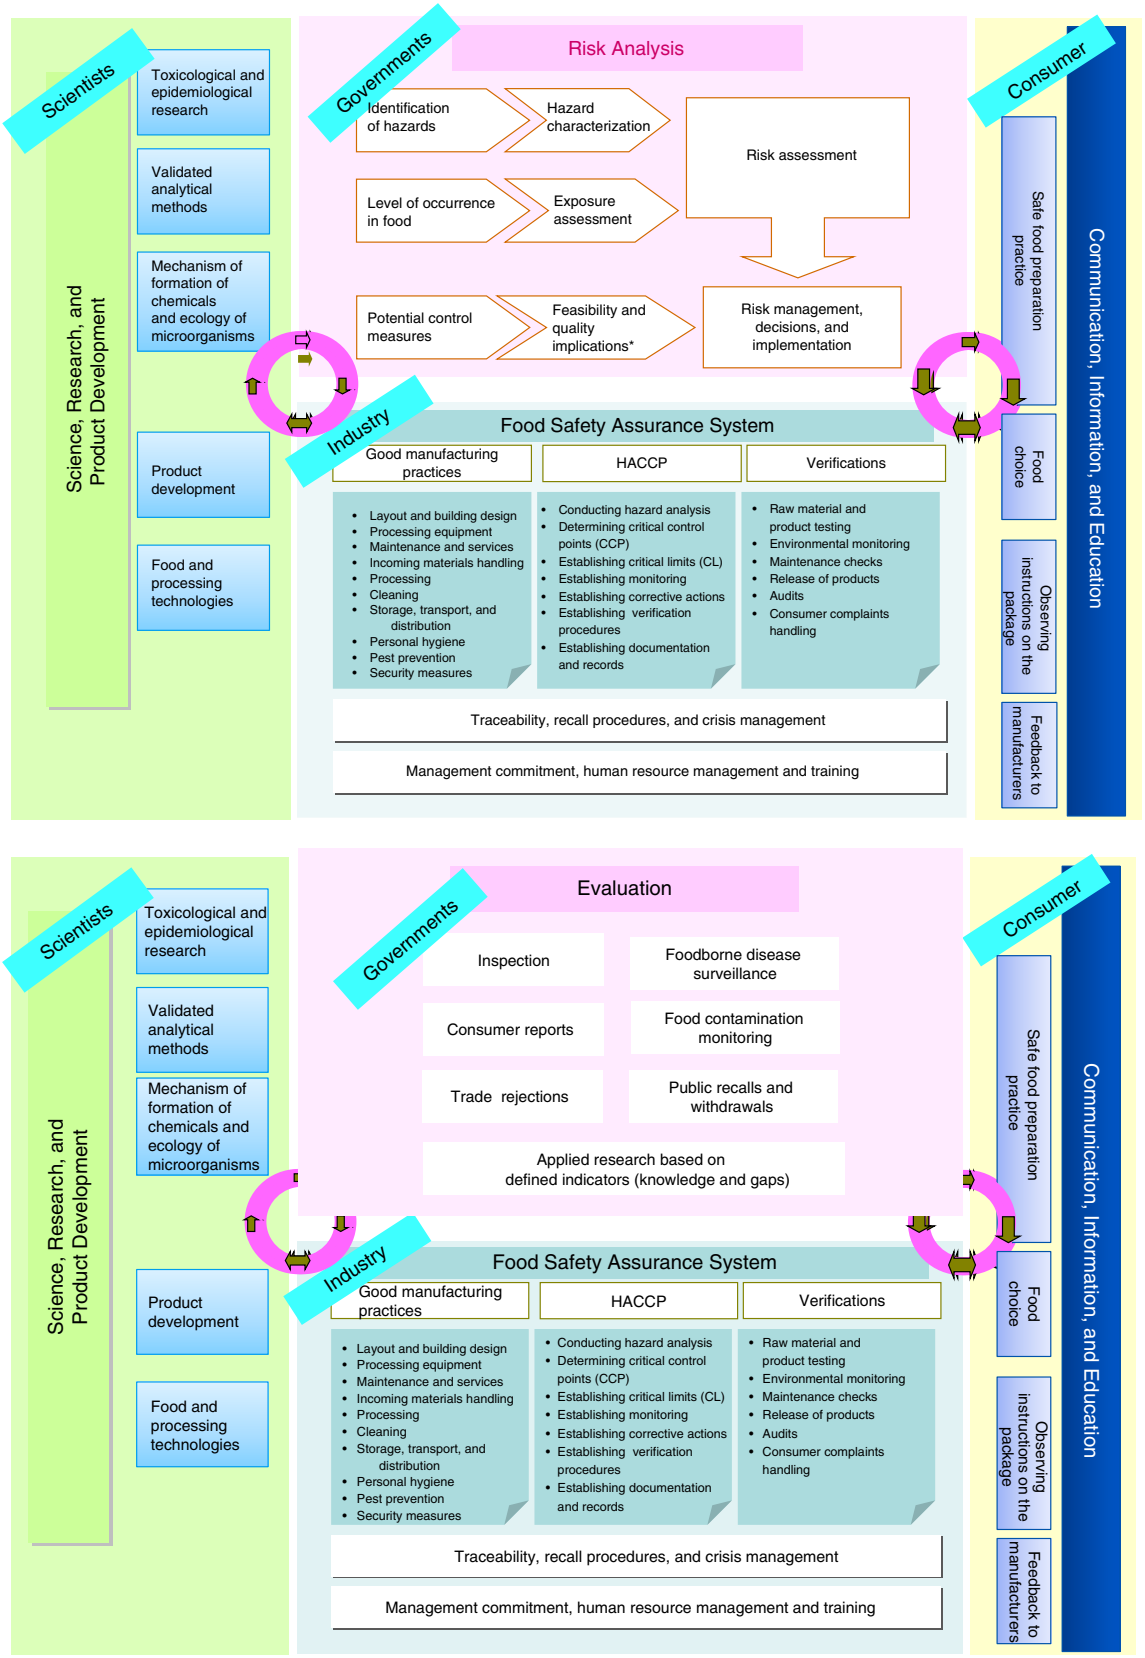
a) Foresee all infrastructures and public health services that are necessary for a good food safety management, such as public health laboratories, water supply and sanitation, etc.,
b) Promulgate laws and regulations, which give priority to public health but which can also meet other societal and environmental requirements,
c) Enforce legislation through inspection, monitoring food supply as well as the provision of advice to the trade and commercial sector, and
d) Provide education to care givers, consumers, travelers, health professionals, and the public at large.

Decisions on measures required to manage risks today are taken in the context of the risk analysis process. There are different types of models for describing the risk analysis process. **Figure 3** depicts the process according to Codex Alimentarius. The process includes: risk assessment, risk management, and risk communication.

As risk managers, regulatory authorities are, among others, responsible for (1) driving the risk analysis process, (2) setting public health goals, and (3) deciding on risk management priorities.

The risk management process itself comprises a number of steps which are briefly discussed here. For more in-depth review, the reader is referred to specific articles in this encyclopedia.

The first step is referred to as preliminary activities. As part of this, governmental risk managers will commission a risk profile for a given hazard or hazard/food. Based on the outcome and in the light of existing data, they will decide if a risk assessment is required, or if it is possible to evaluate various control options. Should risk managers find that a risk assessment is justified, bearing in mind the resource and time investment, they may decide to commission a qualitative or a quantitative risk assessment. In this case, they are responsible



* Include nutritional, microbiological, chemical safety as well as cost and consumer acceptance

Figure 2 (a) Overview of food safety management and the role of different sectors – illustrating the risk analysis process by governmental authorities. (b) Overview of food safety management and the role of different sectors – illustrating the various evaluation activities by the governmental authorities.

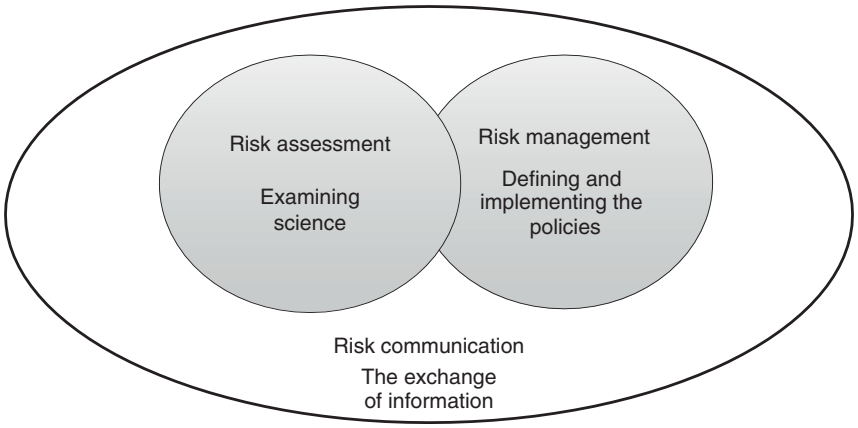


Figure 3 Risk analysis process.

for elaborating a risk policy assessment in consultation with risk assessors and other interested parties. A risk assessment policy is a guidance to risk assessors, outlining information such as:

a) The purpose and scope of risk assessment, for example, sector of the food-chain, types of food, and products to consider.
b) Target populations or subpopulations.
c) Key scientific judgments, particularly when a high degree of uncertainty in existing data or in data gaps exists.
d) The type and sources of data to be considered.
e) How the data should be presented, in particular the types of assumptions and uncertainties.

The process of risk assessment and risk management follows an iterative interaction between risk assessors and risk managers, during which these need to foster mutual understanding and refine the risk assessment so that it responds as closely as possible to the questions posed by risk managers. In deciding on the appropriate control measures, risk managers need to take into consideration a number of other factors, sometimes also referred to as 'other legitimate factors.' These factors vary according to the nature of the hazard under consideration, and can include costs, feasibility, benefits, other risks (e.g., environmental or nutritional), consumer preferences and societal values, such as animal welfare. At times, risk assessment may be required to advise the efficiency of control measures, to develop an understanding of the public health outcome according to different levels of contamination, to have an estimation of the risk of various food/hazards combination, etc.

In managing a risk, depending on the nature and degree, and on other factors mentioned above, risk managers have different options at hand. These range from taking a regulatory action such as those listed below to taking no action.

- Compliance with certain standards (e.g., setting a norm for a chemical hazard or a food safety objective (FSO) or microbiological criteria for a microbiological hazard),
- Labeling,
- Testing and/or certification of foods,
- A specific processing of foods to inactivate pathogens,
- Application of a code,
- Recalling a product in case of an incident.

Alternatively, they may decide to manage the risk by providing education to consumers or requiring the training of food handlers in food service establishments. It can also happen that they decide not to take any action (e.g., if the risk is low or negligible). In any event, the food safety authorities have the responsibility to communicate and explain their decision to the stakeholders.

To identify possible food safety problems and to review the implementation of the risk management decisions and to evaluate the need for any revision in decisions or implementation, the collection of various types of data could be considered. Examples are:

- Inspection reports and evaluation of implementation of risk management decisions by the food industry,
- Monitoring of chemical contaminants,
- Surveillance of foodborne diseases (data from different types of surveillance methods need to be considered),
- Consumer complaints,
- Trade rejections,
- Public recalls, withdrawals and/or incidents, and
- Applied research based on defined indicators (knowledge and gaps).

Other types of information may also be required for planning, improvement, or preventive actions. Examples are trends in incidents and alerts, whether occurring in a country or outside the national boundaries, adequacy of resources, as well as various changes in the society, for example, changes in climate, demography, international trade and travel, or the emergence of new agents.

Industry

The industry is responsible for ensuring that the food that it puts on the market or served in food service establishments is safe, fit for human consumption, and meets the regulatory requirements of the country where it is marketed. They have to consider the regulatory norms for hazards as food safety

standards and ensure that their products are not violating these limits. To meet these responsibilities, the food industry is required to have an integrated food safety assurance system.

A model for this system consists of combining three sets of measures according to three lines of defense (Figure 2):

The first line of defense is the implementation of codes of good practices. These are a set of general measures and principles that have been identified through past experience as necessary to ensure safety and wholesomeness of produced foods; with some adaptation, they are generally applicable to all categories of foods and products and/or establishments regardless of location, specific conditions, and type of business. Depending on the sector, they are referred to as Codes of Good Agriculture Practice, Codes of Animal Husbandry, Codes of Good Manufacturing Practice, Codes of Good Transport or Storage Practice, etc. Very often, such codes are voluntary, but at times they are legally established by regulatory authorities. However, where they do not exist or are not stringent enough, the industry may also develop such codes. The Codex Alimentarius Commission has developed a large number of codes of practices. The recommended International Code of Practice – General Principles of Food Hygiene is one of the 'horizontal' codes with wide application in the food industry.

The second line of defense is the application of the HACCP system. During this process, hazards specific to a food and/or process are proactively analyzed and control measures specific to the identified hazards are identified. For steps that are considered critical for ensuring the safety of the food product, monitoring parameters and critical limits are established and the steps are monitored to ensure that the critical limits are respected at all times. As for codes of practices or any other regulatory requirement where governments have provided limits for a hazard (norms or FSOs) or performance criteria intermediary processes, these need to be considered during product/process design or respected during operations. Needless to say that during the development of a HACCP plan, measures identified for controlling the hazards and the parameters and limits to be respected have to be validated, short of which the HACCP study will become a simple paper exercise. HACCP also has other elements such as corrective actions in case the process is going out of control, and as explained below, verification and documentation.

A strategy that has been used by some governments to assist small or less developed businesses in applying the HACCP system is to develop HACCP-based codes of practices for specific categories of food products. Such an approach is important for small or less developed businesses as they often lack expertise in food safety, and unless assisted by a trade organization, they may not be in a position to carry a HACCP study by themselves. A HACCP-based code of practice for a specific sector combines both the general principles of food hygiene, and the considerations and requirements specific to a given sector.

Frequently, the question is raised about the difference between the code approach to food safety assurance versus the HACCP system and their respective benefits. Originally, a code approach was viewed as a general and prescriptive system of management of food safety in a business. Subsequently, HACCP was recommended by public health authorities to promote a proactive approach based on the analysis of hazards in foods or processes, before these lead to an incident. When applying the HACCP system, hazards specific to a particular food product, process, and to the conditions in which the food is prepared, are identified and control measures specific to the hazard in question are devised. In this way, as opposed to codes which are for general guidance, through the HACCP system, control measures are targeted at hazards specific to the product (raw material or conditions of production). However, with experience, it became evident that both approaches have their respective values, and that HACCP would be more efficient if some basic hygienic conditions and preventive measures were in place. Today, in food safety assurance systems of the food industry, these are referred to as prerequisites, and it is recognized that it is by combining both approaches that the optimum conditions of food safety management are attained.

Very often, the documentation required as part of HACCP has given the system a negative image of being burdened by paper work. However, records and documentation are essential as support material for communication between members of the HACCP team and/or with time, for the maintenance of the plan, i.e., for the HACCP team to be able to consider the need for any change in the plan and thus ensure that the system remains valid and up-to-date. Also, records are required to provide evidence to customers and/or inspectors on the adequacy of measures.

The third and last line of defense is verification activities. These are also part of the HACCP application, but to delineate between measures implemented for prevention and those required for verifying that preventive measures are effective and performing correctly they are presented separately.

As for the governmental evaluation process, verification activities include all tests and other data collected to verify that preventive measures are implemented and achieve the objectives set. Verification should not be mistaken for validation, which is a process to ensure that control measures are effective to achieve the objectives desired. The validation process is usually implemented during the product and process design stages, or when a change has been made in product design during its manufacturing. If verification data indicate that a product is not meeting a set standard, even though the plan has been implemented, validation of control measures may be put in question.

In principle, where codes of good practices and the HACCP system are optimally implemented, a high degree of safety can be assured. Nevertheless, verification measures are important to detect any dysfunctionality in the system. They also provide evidence of compliance with the food safety standard and should not be stopped on the grounds that data on contamination are negative, as data are needed for proving the performance of the food safety assurance system, at all times. Examples of verification measures are:

- Raw material and end-product testing
- Environmental monitoring
- Calibrations and other maintenance checks
- Release of products
- Audits
- Consumer complaints handling

Should verification data indicate non-compliance, the adequacy of the implementation of the HACCP system and the prerequisites must be examined in the first place. In absence of any non-compliance, the validation of elements of the HACCP study can then be questioned.

At times, in spite of all measures, it can happen that a raw material used in a product is contaminated or a product which is contaminated is marketed. Through a traceability system, i.e., information on the source of raw materials or the customers who have received the product, a contaminated product can be traced and recalled. Regulatory authorities in some countries require that the traceability system of an establishment ensure that information on the source of a raw material or the destination of a final product be available for one step up or one step down. With the globalization of food supply and the passing of food ingredients through various traders, it is sometimes difficult to ensure precise or valid information on the condition of the production of raw materials. Where information on traceability is lacking, the investigation of outbreaks and identification of implicated food becomes more difficult as observed in an outbreak of *Salmonella* in paprika in the US, originally attributed to tomatoes, and subsequently consumers may be more exposed to a contaminated product for a longer period of time. The weaker the traceability, the larger the scale of the outbreak. This was demonstrated in the dioxin incident in Ireland where a full product recall was conducted for pork meat, whereas for beef meat it was possible to limit the recall to the contaminated product because after the BSE crisis, a traceability system was established for beef products. Similarly, in the food manufacturing industry, the finer the traceability, for example, indicating the date and time the product was produced, the smaller the product waste in case of recall.

Finally, the entire food safety assurance system should be supported by a well-performing crisis management system to protect consumers from exposure to contaminated products.

Fundamental to all these systems are the training and education of the staff as well as the management commitment. Therefore, fostering a culture of food safety for people, from their training to their motivation and understanding of their perception and constraints, constitutes one of the most important pillars of food safety management in industry and in governmental functions. The importance of an organization culture cannot be emphasized enough. Reporting of any non-compliance or of a risk-prone situation at an early stage can contribute to preventing 'near misses' situations, and thus the likelihood that one of these resulting in an incident.

Consumers and Informal Sector

Consumers at large and domestic and professional food handlers in particular, also have an equally important role in food safety. These include, but are not limited to:

- Observation of good hygienic practice in the preparation of food.
- Reading information (e.g., use 'by date' of products, target consumer) on the labels of products and observing the instruction for the preparation and storage of products.
- Reporting defective (unsafe) products to the public health authorities and/or manufacturer.
- Be discriminatory in the selection of products and establishments to exclude those that may present a risk for health and do not respect food hygiene, do not meet regulatory requirements or have unethical practices.

To enable consumers to assume their responsibility in hygienic handling of food as well as to judge potential risks with certain products, practices or establishments, consumer information, and education is the key. This is best carried out by professionals who are both trusted by the general public and who also have contact with the pubic in the framework of their work. An example of such a professional group is health professionals, or teachers in the schools. Unfortunately, these professionals are not always aware of or attentive to the importance and magnitude of the problem; many perceive foodborne illnesses as benign self-limiting illnesses, or are misled by the poor statistics in this area or their erroneous interpretation.

Academia

Scientists in general, whether they work in academic institutions, in governments, or in industry, also have an important function. With the trend in evidence-based decision-making and taking science into consideration, be it life or social sciences, the role of this sector in the risk analysis process has increased during recent years. Their integrity, excellence, and relevance make them ideal communicators to managers (e.g., report of their results, articles) or to the general public (e.g., interviews in the mass media). As such, they play an important role in both the management of food safety (in particular risk assessment and risk communication) and the management of a crisis. However, they may also be the source of a crisis, should they fail in their risk assessment or have an inappropriate risk communication practice.

On the technical aspects, scientists contribute to food safety management by providing different types of scientific data and their assessment, which is necessary for decision-making. Examples are:

- Toxicological information, mechanisms of contamination of foods with chemicals, or their formation,
- Ecology of microorganisms and epidemiology of foodborne diseases,
- Validated analytical methods,
- Process and technologies to control hazards,
- Consumer perception, beliefs, and practices.

In industry, scientists can minimize risks associated with products and processes by designing them out during product development and defining necessary control measures to manage the operational risks during the production or manufacturing of foods.

Additionally, scientists can further contribute to the management of food safety by creating tools to make information on food safety easily accessible to all the actors in the society. The participation of several hundred scientists from different sectors in the preparation of the Encyclopedia on Food Safety is an example of such a concerted effort and of contribution of scientists to the management of food safety.

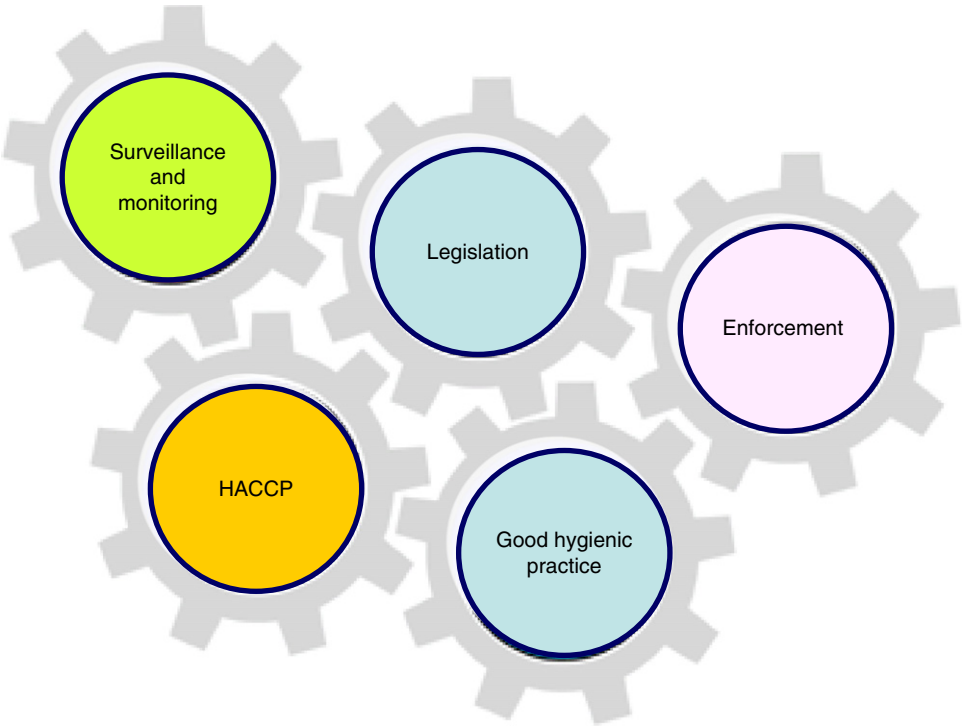

Figure 4 The need for an interconnected food safety management system.

Conclusion

In summary, the history of food safety can be considered in three major eras:

- A time where consumers were managing the safety of products directly,
- An era where governments were managing food safety by testing products and removing contaminated or non-compliant products from product; food was considered safe unless tests would indicate otherwise.
- An era where the food business has become responsible for providing evidence that they have taken necessary measures to prevent contamination of foods and ensure the safety of products. Since then, the role of governments has shifted from identifying potentially unsafe food or unsafe food practices to supervising and verifying the implementation of a food safety management system by industry.

In the contemporary world, due to the huge number of risks associated with food, the complexity of operations and the food chain, international trade in food, the diversity of food products as well as consumer practices and perception, the management of food safety has become very complicated. These have required the establishment of an objective and a transparent system of decision-making, taking into consideration both science and the views of stakeholders.

To manage food safety efficiently, a concerted effort is undoubtedly needed on the part of all sectors, i.e., governments, industry, consumer, and academia. Each sector has a specific role and responsibility; however, to have a well-functioning system at the national or international levels, it is important that different elements of food safety be interlocked, like the gears in a machine, that different sectors work in a concerted and coordinated effort (Figure 4). Today, there is adequate science and technical know-how to ensure the safety of the food supply, at least with regard to most hazards that are known to science. It is weakness or neglect in the implementation of the know-how, past experience, and policies that are often the source of major adverse events. However, while collaboration between sectors is needed, the independence in research, in the decision-making process at governmental level and in implementation is the corner stone of successful and sustainable food safety management. In doing so, consumers' health should be the first priority.

PUBLIC HEALTH MEASURES

Risk Governance

M Dreyer, DIALOGIK Non-Profit Institute for Communication and Cooperation Research, Stuttgart, Germany

Glossary

Concern assessment A systematic scientific process of gathering and analyzing data on social responses to food risks, insights on risk perception, and other impacts related to downstream consequences of food consumption.

Framing Relates to risk assessment policy (in the terminology adopted by Codex Alimentarius) and includes the initial analysis and scoping of a risk problem and the setting of terms of reference on which the assessment authority will base the assessment.

Risk assessment Primarily a scientifically driven process aimed at understanding risk and concluding what we know about risk. It comprises the task of identifying and exploring the types, severity, and likelihood of the (normally undesired) consequences related to a risk source.

Risk evaluation The process of determining the value-based components of making a judgment on risk. This includes risk–benefit balancing or incorporation of quality-of-life implications and may also involve looking at such issues as the potential for social mobilization or at prerisk issues such as choice of technology and the social need of the particular operation giving rise to the risk.

Risk management An intrinsically political process primarily aimed at deciding what to do about risk. It includes generation, selection, and implementation of management measures as well as monitoring of how these measures perform in practice.

Stakeholder Socially organized groups that are, or will be, affected by the outcome of the event or the activity from which the risk originates and by the risk management measures taken to address the risk.

Food Risks as a Contemporary Governance Challenge

Food safety is essential for people's health and well-being. In many parts of the world, mainly in the highly developed industrialized countries, it is regulated as part of the public health policy. People here, expect to be widely protected from the contamination of the food supply by the competent food safety authorities. This expectation is met with frustration when food-safety scares occur of the kind that afflicted Europe between the late 1980s and late 1990s, most notably mad cow disease with its most wide-ranging implications in the economic, political, and institutional arenas. Another more recent example of a food-safety scare that gained global attention is the Chinese milk powder incident disclosed in 2008, where milk and infant formula adulterated with the substance melamine resulted in a large number of sick children and several fatalities. These negative experiences do not necessarily – and presumably only in exceptional cases – result in a constant worry for consumers about the safety of their food. However, consumers have become more sensitized to externally imposed food risks because their trust in the competent authorities has been shattered.

By the late 1990s, the prevailing diagnosis in European policy circles was that the series of food-related scares and controversies, most notably dioxin contamination, bovine spongiform encephalopathy (BSE), beef hormones, and genetically modified organisms (GMOs), had seriously reduced the level of public trust in both food safety and the competence of the authorities formally entrusted with assessing and managing food risks. In Europe, this diagnosis was the main reason why policy-makers decided to give top priority to risk governance. The European Union (EU) and many of its Member States subjected the rules and routines of food safety regulation and the roles and responsibilities of public and private actors in food safety management to a thorough review. Restoration of trust has been one of the key objectives of the resulting institutional and procedural reforms.

The so-called BSE crisis also had international repercussions. In Japan, for instance, it gave impetus to the establishment of a new food safety commission. Food safety incidents in combination with enhanced public awareness of safe food have triggered reform in threshold countries such as China where the food safety regulation system has undergone substantial legal and institutional change since 2009. Clearly, in a comparative perspective, food safety governance has been given exceptionally high priority in contemporary Europe. However, for several reasons we can assume that in many more parts of the world, political and public attention to food safety governance may grow or continue to grow in the near future. These include: the significant increase in the diversity of the food supply including

entirely new or fundamentally modified products for which there exists no or only very little experience in safety matters; the progressing trade liberalization in an ever growing and increasingly competitive global food market and the heightened concerns of consumers faced with this development; and the intense and persistent transatlantic trade disputes over hormone-treated beef and GMOs which, subjected to the dispute settlement mechanism of the World Trade Organization (WTO), have been attracting global attention.

All this has made risk governance in the food safety area a particularly interesting field of empirical risk research. A number of studies dealing with the aspects of food risk governance have been carried out over the past decade in research fields such as science and technology policy, risk regulation politics, participatory governance, and risk/benefit perception and communication. This article, will focus on three themes that are dealt with prominently in recent publications. These are: (1) the demarcation and coordination between risk assessment and risk management; (2) the opportunities and challenges of enhancing stakeholder and public participation in risk governance; and (3) the particular challenge of value conflicts for the governance of food risks. In the face of the legitimacy and trust crisis in Europe and the fierce transatlantic trade disputes, these themes have shaped regulatory debates and policy at national, EU, and transnational levels over the past 15 years. Many scholars identify them as critical dimensions of an innovative risk governance regime, which can help to improve scientific and democratic legitimacy of food safety regulation. We will address these themes as major governance challenges that public authorities face in dealing with food risks, and use mainly the European situation and problems as examples. Before doing so, we shall first outline the concept of risk governance.

The Concept of Risk Governance

In the past decade, the term 'governance' has experienced tremendous popularity in various research fields. These include international relations, comparative political science, policy studies, sociology of environment and technology, and also risk research. Although there is no generally agreed definition of what constitutes 'risk governance', this concept is typically understood as involving the translation of the substance and core principles of the governance term to the context of risk and risk-related decision-making. This implies that the concept of risk governance pays special attention to collective decision-making on risk as a multiactor and multilevel process involving new modes of regulation and collaboration. Within a broad notion, risk governance refers to the complex web of actors (governmental and nongovernmental), rules, conventions, processes and mechanisms concerned with how the relevant food risk information is collected, analyzed, and communicated and how decisions on risk management are taken and implemented at different policy levels (national, transnational, global). Food risk governance (or the similar term 'food safety governance'), in this perspective, is not only understood to include but also to extend beyond the three conventionally recognized interrelated components of risk analysis. These are risk assessment (aimed at understanding risk), risk management (aimed at acting on risk), and risk communication (aimed at informing all relevant actors and exchanging messages about risk and meanwhile predominantly understood as an activity cross-cutting assessment and management). Food risk governance also involves the collaboration of and coordination between public authorities and the commercial and civil society actors and wider contextual factors such as institutional arrangements, regulatory styles, legislative procedure, and the political culture. In the food safety literature, the concept of risk governance implies not only a scientific dimension but also a political, institutional, and a cultural dimension.

The Relationship Between Risk Assessment and Risk Management

The way in which science and policy are interrelated in processes of collective decision-making around risk issues is an aspect to which the concept of risk governance pays special attention. A particular focus here is the way in which this interrelation could and should be accounted for in the organization of the relationship between risk assessment and risk management.

Since the mid-1990s, the question of how to demarcate and coordinate between food risk assessment and management activities has substantially gained in importance as a research aspect. This has mainly been due to the mad cow scare, which made this question a salient policy issue in wide parts of Europe. The BSE crisis was interpreted as a result, at least partly, of a regulatory regime marked by a nontransparent and inappropriate intermingling of the roles of assessment and management, and of scientific and nonscientific considerations. The Committee of Inquiry into BSE, set up by the European Parliament, in its report deemed a blurred relationship between science and policy to have been one of the major shortcoming of the European Communities policy – in the years before 1996 – as well as of the approach of the UK from where the BSE crisis originated. It concluded that the EU institutions had given precedence to national interests of agriculture and industry at the expense of public health protection. Suspected of abetting partiality and obscurity in dealing with food risks, the traditional approach of rather seamless scientific and political activities became a subject of intense debate, scrutiny, and reform. Up to the mid-1990s, both EU institutions and EU Member States were neither systematically differentiating between activities of risk assessment and risk management, nor did they structurally separate organizational or institutional responsibilities. It was normal for the responsibility of assessment and management to be handled by a single institution, for those responsible for risk management to be closely involved in preparing and deciding risk assessments, and for scientific advisors to be expected to provide specific advice on particular policy issues. With the BSE event, the appropriateness of this approach became heavily contested.

The use of mechanisms designed to assure a stricter separation of the risk assessment function from decision-making on management measures formed the core of the reform of existing food safety institutions in Europe. In terms of loss of public trust and social legitimacy, the remedy resorted to, in this approach is the supposed trust-generating power of what is represented as independent risk assessment. Safeguarding

scientific analysis against distortion by inappropriate policy influences and considerations is intended to re-establish and assure the credibility of risk assessment activities and results by which risk management decisions are to be made. This reform approach is especially pronounced at EU-level and in countries such as Germany and France where responsibility for the functions of risk assessment and risk management have been allocated to different institutions.

Food safety governance reform in Europe did not, however, settle all the disputes over the assessment–management relationship. Rather it has tended to accentuate them. This has been described and discussed in a number of recent empirical studies which deal with theoretical and practical aspects of this relationship. These studies indicate that there exists wide appreciation – within and beyond Europe – that the revised EU food safety system has its basis in the risk analysis framework outlined by the World Health Organization (WHO) and the Food and Agriculture Organization (FAO). Very broadly, this framework is comprised of the three interrelated but functionally separated components: risk assessment, risk management, and risk communication. Nowadays, this framework underlies and informs food safety regulation at the EU-level (and at national level in many European countries) as well as in the USA and also at the global level in the form of the standard-setting activities of the Codex Alimentarius Commission (a joint World Health Organization and Food and Agricultural Organization standard-setting body) whose standards have acquired legal authority with the creation of the WTO in 1995. The risk analysis framework advocates the functional separation of assessment and management on the basis of the conception that regulatory actions rest on two basic components: first, knowledge about the seriousness of risks; and second, legally prescribed procedures, norms, or standards of how to handle risks. Even if the same knowledge is processed by different regulatory agencies, the prescriptions may vary in many aspects concerning selection rules, interpretative frames, action plans for dealing with evidence and uncertainty, and so on. National culture, political traditions, and social norms influence the mechanisms and institutions for specifying the role of knowledge for policy formulation in the respective political arena. The separation of risk assessment and risk management is a reflection of this fundamental difference between the rather universal and intersubjectively testable knowledge claims about the seriousness of a given risk and the more idiosyncratic procedures to design policy options on how to handle risks once they are identified and assessed, most preferably in quantitative terms whereas qualitative terms are often a reasonable addition or the only possible option.

In the Western world and also in Japan, the functional separation of food risk assessment and food risk management appears to be largely beyond dispute. In contrast, the practice of institutional separation of the respective responsibilities has been critically discussed in both policy and academic circles. The growing food safety governance literature has, in particular, criticized the idea that often underlies the practice, that the envisioned performance of assessment and management tasks in strict separation and sequence could safeguard risk assessment as a purely scientific exercise. Recent studies in this field assert that the concept of strict segregation has never represented real practice anywhere in risk regulation, not even in the revised EU food safety system. It was exactly the institutional and geographical divide here that had made it increasingly clear to the risk professionals that there are interfaces between assessment and management at which exchange and coordination was vital. It is obviously more of a challenge to organize this interaction if this implies coordination across different institutions located in different parts of Europe. In this view, a certain extent of interaction between those responsible for risk assessment and those responsible for risk management is not merely admissible, it is even conducive to dealing effectively and legitimately with food risk problems.

This concept of a cooperative relationship is in accordance with the Working Principles for Risk Analysis of the Codex Alimentarius Commission. These Principles emphasize that food risk analysis is an iterative process and interaction between risk managers and risk assessors is essential for its practical application. Scholars of risk regulatory policy and science and technology policy have expressly supported this view. They have persuasively argued that there are inherent interlinkages between the scientifically orientated activity of assessing food risks and the politically orientated task of managing these risks. The specific approach to a particular assessment inevitably includes nonscientific considerations and value judgments (be they explicit or implicit), which cannot be derived from and determined on purely scientific grounds. Such considerations include, for instance, the selection of impacts to assess, the disciplinary perspectives to shed light on these impacts, the choice of more or less conservative safety factors, and the ways to deal with different sources and types of uncertainty. So far, the concept of a risk assessment performed in a political vacuum and based on pure science is misleading even in theory. This is a point that the National Research Council of the USA had already made in its famous 1983 book on dealing with environmentally induced health risks (*Risk Assessment in the Federal Government: Managing the Process*). While underlining the need to separate risk assessment from management, this seminal work in the field of risk research emphasizes, at the same time, that it was an erroneous belief that full separation at the organizational level would be a way to effectively separate science from policy. Both factual and normative judgments play a role in risk assessment. Therefore, mutual communication between assessors and managers would be desirable and should not be disrupted. In the USA, the organizational conditions are more conducive to this interaction than in the EU. The US Food and Drug Administration (FDA) is a full-blown regulatory agency which has the mandate to deal with both the scientific and policy aspects of risk appraisal and decision-making. There is no institutional divide between assessment and management in the US food safety system. However, within FDA there are different departments that deal with assessment and management separately.

At the EU-level, there exist clear tensions between efforts to rebuild trust by assertion that with the new two-institution solution, scientific assessment would be insulated from political judgment and the practical requirements of coordinating assessment and management activities. Recent studies putting forward this problem diagnosis have also discussed ways to

account for the interlinkage between the scientific and the political aspects of food safety governance without compromising the generally agreed functional differentiation between assessment and management.

One proposal is to organize those steps in risk governance in which knowledge and values are closely intertwined and which are, therefore, considered as lying at the interface between assessment and management as separate additional governance stages within specified procedures and structures, ideally performed jointly by assessors, managers, and also key stakeholders. Two of these interface tasks are identified. The first refers to activities carried out before the risk assessment starts. The main task here is the definition of the problem in question (in consideration of possible different perspectives of how to conceptualize the food issue) and, related to that, the determination of the significant context conditions, the assessment boundaries, and the selection of conventions (scientific, political, and legal) and procedural rules needed for the assessment. This task is variously referred to as framing, preliminary assessment, preassessment, definition of risk assessment policy, or similar terms. The second task refers to activities carried out after the risk assessment has been performed. They are oriented toward arriving at a judgment on the acceptability of the risk based on balancing pros and cons, testing potential impacts on the quality of life, discussing different development options for the economy and society, and weighing the competing arguments and evidence claims in a balanced manner. This task is typically referred to as evaluation. Under current regulatory arrangements, these two sets of activities are often exercised in a manner which lacks transparency, and the associated responsibilities are unclear and accountability is not given.

There is a clear need to clarify and render more explicit terms for cooperative interaction between managers and assessors (and also key stakeholders). Crucially, the formalization of preassessment and evaluation activities is considered a means to achieve greater transparency and accountability in the ways in which knowledge and value inputs are articulated in risk management decisions.

Stakeholder and Public Participation in Risk Governance

One of the defining features of the governance term is that it refers to the interaction between various actors in public problem-solving. Accordingly, food risk governance emphasizes that analysis and management of food risks cannot be confined to public food safety authorities. It denotes the involvement of a wider array of actors in pursuing risk governing purposes. This also includes policy-makers, economic actors, scientists, and other experts not directly affiliated to food safety authorities, and the affected and interested civil society actors, besides regulators and official expert advisors.

Although the multiactor perspective is generally understood as an inherent element of the governance concept, there is an emerging literature focusing specifically on promises and pitfalls of various actors in the processes of public food safety handling under the heading of 'participatory governance' or 'inclusive governance'. Several scholars have argued that the governance process as a whole should be rendered more sensitive and responsive to the relevant knowledge (systematic, practical, and experiential) and the preferences and values of affected and interested parties. They claim that mutual exchange around framing assumptions, knowledge claims, and acceptability judgments in relation to food risks and ways to manage them may be able to substantially improve the final decisions. In this view, purposive multiactor dialog is a tool to shed light on the different dimensions of a food safety problem as well as to stimulate reflection, mutual learning, and more balanced judgments. Such an inclusive approach is also meant to improve trust. More inclusive and cooperative forms of food risk policy-making and regulation are often part of theoretical and empirical analyses of the trust and legitimacy crisis in Europe and the reform efforts that followed.

Current approaches to food risk governance at EU-level and in a number of European countries indicate a greater role for the stakeholder and public involvement in achieving appropriate risk-handling solutions. At the EU-level, there have been growing efforts during the past couple of years to involve stakeholders in both the management and assessment of food risks. Declarations of the value and the need for connecting with citizens and stakeholders, open dialog, and understanding and addressing the concerns of the stakeholders and consumers now present a standard part of the official rhetoric of many European policy-makers, regulators, and expert advisors. Empirical research into practical implementation of the reform objectives has critically commented that reform in the participatory policy in Europe has been largely confined to a broadening of consultation activities using, also, new mechanisms such as internet-based tools. There is continuity in organizing public involvement in most part as the elicitation of responses to predesigned proposals. Some high-profile dialog-based participation procedures have been carried out in the past decade, including, for instance, the GM Nation-debate in the UK. However, such exercises are often stand-alone events, mainly intended to elicit citizens' attitudes toward a new technology or a specific issue, and only very loosely (if at all) coupled to the official policy-making and regulatory processes. In view of this, scholars of science and technology policy and risk policy have asserted that food safety governance activities should be communicated by symmetrical two-way exchanges with the potential to really empower different social actors to provide knowledge, evaluations, and policy advice. Such deliberative efforts are particularly helpful in situations in which the scientific uncertainty and social controversy around a food safety case make risk governance especially challenging.

Some studies have pointed to the complex relationship between participation and trust. They have stressed that increased participation may actually destroy the public trust if applied in inappropriate circumstances. One context variable that deserves special attention, in this view, is the level of trust in the food safety authorities. If a regulatory system wants to draw on this trust resource, too much openness and participation in the risk assessment and management processes may jeopardize this goal. Inputs by stakeholders may be seen as compromising scientific objectivity and independence and as challenging the claim that authorities act in the best interest of

all people. The resistance of the Swedish National Food Administration to extend participation in the food safety regulation when the BSE crisis shook Europe has been interpreted as a purposeful and reasonable way of acting in a situation of high-trust that continued during and after the crisis. However, empirical studies demonstrate that even highly trusted organizations need to document that they are open to public demands and be transparent about their assessment and evaluation procedures. Transparency may not always help to gain trust but being secretive and hiding information has most often contributed to destroying trust.

Other general challenges and pitfalls of participatory risk governance that have been discussed in relation to dealing with food risks are over- and under-representation of certain actor groups, cumbersome decision-making leading to undue delays in the regulatory processes, and an overkill of participatory procedures abusing the scarce resources of both the responsible institutions and those invited to become involved. Stakeholder fatigue has developed into a buzzword in the academic as well as stakeholder circles in the past few years. There seems to be general agreement among scholars that exhaustive levels of participation on every food safety issue are definitely not desirable. Recent studies have stressed that the level as well as the form of participation would need to be matched with the level and nature of intractability of the respective risk issue. This was essential for ensuring practicality, efficiency, and legitimacy of participatory risk governance.

The Neglected Challenge of Value Conflicts

Recently published research work has underlined the need to distinguish, generally more carefully, between different aspects and contexts in food safety governance. This work offers suggestions on how to achieve greater integration of science, precaution, and public involvement in the current arrangements for European food safety governance. The main argument is that strongly contrasting implications are presented by food risks that may be seen (respectively) as: routine in nature, definitely prohibitive in their consequences, or in some way intractable – either because their implications are scientifically uncertain or are evaluated very differently by political and societal actors. Each of these broad aspects and contexts of food safety, the argumentation goes, demands different kinds of attention and different modes of coordination between the specialists, political decision-makers, and the corporate and civil society actors. Each in turn, therefore, also requires at least partly distinct technical methodologies, deliberative processes, and institutional configurations.

To devote different kinds of attention to food risk problems includes a differentiated scoping of the assessment exercise. Although in most cases routine health risk assessment will be sufficient, in other cases an additional analysis of the environmental, social, economic, and ethical impacts might be required. Recent studies have emphasized that a broader assessment is required in relation to food safety-related issues which are associated with deeply held value-orientations. They have underlined that for most people, food safety is not merely about absence of hazardous substances or unsafe levels of substances in the food they buy. Instead, in many instances, individuals, social groups, and different cultures also link wider concerns and expectations to a risk issue. These may be cultural, religious, or philosophical beliefs, concerns regarding the welfare of animals used in food production, or the desire for less high-tech in food production and more natural foods. Currently, such concerns are part of discussions in relation to topics such as the use of animal cloning for food production and the application of nanotechnologies for food-production purposes. The persistent controversy over GM food is an often cited example in this respect. Several studies dealing with the GM debate have suggested that divergent interests concerning the material risks and benefits relating to food safety or nutritional quality and disputes on the relevance, quality, and sufficiency of knowledge have also fueled this conflict but may not have acted as the prime driver. In this perspective, the main motives of opposition and criticism are rather assumptions or convictions that GM food does not meet a social need, encourages human hubris to model everything as one sees fit, and is opposed to one's own idea of life or the world. In short, the prime motives are identified as normative or ethical in nature.

Earlier conceptual work in risk research has classified conflicts about worldviews and value systems as the third (most challenging) level of risk debates. The first level refers to the factual evidence, probabilities, and uncertainties; the second level to the institutional performance, expertise, and experience. Recent empirical research suggests that current regulatory regimes in the Western world – including the revised EU regime – usually address issues of levels 1 and 2. They might be likely, however, to fail to address the third level, i.e., the level of values and visions, because such orientations were usually not addressed in a proactive, systematic, and direct manner. Suggestions for how to put such an innovative approach into practice include the following procedural arrangements. First and foremost, food safety issues should be screened for value-based conflict potential at an early stage in the governance process (when the terms of reference for the assessment are set). If this potential is identified, the advice is to complement the assessment of the physical risk(s) with a concern assessment. Concern assessment is defined as a systematic process of gathering knowledge about the concerns, expectations, and perceptions that individuals, groups, or different cultures may link to a certain risk and about the associated potential of social controversy and conflict. This knowledge can be used to assess the likeliness of wider socioeconomic and sociopolitical impacts related to the source of a food risk or indeed risk management practices.

If the results of this appraisal confirm the potential or existence of a critical value-based conflict, a public participation procedure should be designed to provide more reliable information on the question of framing of the issue concerned and on the dimensions of the value conflict that need to be addressed in the decision-making process on management measures. These procedural devices are not presented as means to resolve conflicts based, for instance, on divergent notions of the nature and underlying worldviews. The idea is rather that they can guide risk managers in the choice of the management instruments. With labeling, these include a powerful (however, also trade sensitive) tool for letting citizens and consumers make their own value judgments about food issues and incorporating sociocultural

perceptions and preferences across lifestyles (and countries) into food safety regulation.

Whether there is a necessity to address the third level of risk debates and deal with value conflict depends on the broader cultural context in which a specific food issue is embedded. In the case of GMOs, the need has been much greater in the EU than, for instance, in the US where the issue has never been as controversial as in Europe. Scholars of the regulatory policy have traced the different degrees of public controversy and the different regulatory responses (in contrast to the EU, GMOs are not subjected to specific regulation in the US regulatory system) partly to the higher value that European consumers and regulators attach to traditional food practices than US consumers. In the EU, it is a widely held belief that food should be produced in the most natural way possible and the criterion of naturalness enjoys great popularity.

Outlook

Some scholars assume that attributes such as natural, authentic, and traditional will continue to gain in importance across Europe as motives of consumer choices. Under these conditions, the controversy over GM foods may establish a precedent on how Europe will debate and regulate novel food production, processing, and packaging technologies that are present in addition to challenging scientific issues complex normative and ethical questions. More culturally informed strategies to handle food risks could gain in importance in European food safety governance. These are, however, limited by an international framework for the setting, arbitrating, and harmonizing of the world food standards. This framework is made up of the WTO dispute procedures, the Agreement on Sanitary and Phytosanitary Measures (SPS) which is part of the Final Act of the General Agreement on Tariffs and Trade (GATT) and stipulates global harmonization of standards for which the Codex Alimentarius Commission plays a pivotal role, and the Technical Barriers to Trade agreement. The SPS Agreement requires members to justify the food safety regulations that they apply and demonstrate that any trade-distorting effects are proportionate. Justification may be done by the adoption of international standards or through risk assessments which must satisfy certain requirements. The global framework in which European food safety regulation is embedded essentially encourages the reliance on a standardized, international, and science-based approach to regulation. In this approach, risk assessment is a technical, nonpolitical, and value-free exercise. Accordingly, cultural factors may enter the stage of choosing risk management measures, but not the stage of determining whether there is a food safety risk.

Institutional responses to wider concerns, however, must not be restricted to legislative and regulatory reforms. As the GM food conflict shows, the corporate sector may be prepared to react to such concerns more easily than governmental or supranational authorities. GM food was first boycotted by British supermarket chains before retailers across Europe followed the example. The responsiveness of the food industry and the retail sector – for instance, by increasing differentiation of products, production methods, and channels of distribution – will depend, among others, on the extent of mobilization of consumer, environmental, and other civil society organizations affected by and interested in food safety related matters. At any rate, social analysis should not be restricted to how public actors deal with the multifaceted challenges of many food safety issues. Instead, it should give equal importance to the roles of the corporate sector and civil society and also partnerships between the public and private actors. All of these actors contribute to food safety governance. In Europe, decline in public trust in food safety authorities and increased public awareness about food-related incidents have given a significant impetus not only to regulatory reform but also to major changes in governance structures in the private sector. The enactment of public mandatory standards has been paralleled by a shift toward more so-called self-regulation mainly in terms of the development of private food safety and quality standards. The tightening of both the public and private standards has affected access of developing countries to export markets. This has been recognized as one of the major challenges for future food safety governance at both national and global levels.

Challenges of Developing Countries in Management of Food Safety

PO Lamuka, University of Nairobi, Nairobi, Kenya

Introduction

The past few decades have posed tremendous challenges to developing countries in ensuring adequate supply of safe and quality foods for the domestic and international markets. The major priority in management of food safety has been to ensure access to the international markets so as to generate valuable foreign exchange. Unfortunately, less attention has been paid to prevention of foodborne disease locally.

The structure of international trade in agricultural products has changed significantly over the past decades for developing countries. There has been a substantial increase in exports of fresh produce, compared with manufactured or processed products. In the current global food market, the protection of human, plant, and animal life and health is a challenge that must be addressed by developing countries through development of internationally recognized food safety systems. However, the developed countries, which are major markets, have been tightening their controls so as to provide a 'high level' of protection for their consumers.

Most food safety challenges facing developing countries can be attributed to the management system's inability to detect potential risks and gaps, share information, plan together, and identify appropriate strategies for collaborative management of food safety in the supply chain and protect the consumer. In developing countries, the prime responsibility of ensuring food safety in the food supply chain is regarded as a responsibility of government.

Prominent food scares, caused by bacterial (e.g., *Salmonella* and *Listeria monocytogenes*) and chemical (e.g., mycotoxins) contaminations and changes in the international trading environment have elevated food safety to the forefront of international agri-food policy and public health concerns. These concerns were exacerbated during the 1990s by 'mad cow disease' and the 'dioxin crisis' and forced regulators to rethink food safety strategies, integrating the various components of the value chain and introducing traceability requirements. In the new millennium, food production and distribution have become even more complex and market choices for consumers even wider. The media and consumers have developed a much greater interest in food safety issues following a number of food scares internationally.

The changes in the international trading environment include an increased emphasis on food safety regulations in trade, introduction of strict food safety standards, reorientation of food quality techniques toward preventive management, and a shift by regulatory agencies toward process-based standards and mandatory Hazard Analysis Critical Control Point (HACCP). These changing trends raise several important food safety management challenges and opportunities for developing countries. The most obvious concerns are the impact these have on the heavily relied on agricultural commodity export markets and domestic food sector.

Many developing countries are pursuing value addition strategies which are geared toward expanding their food export markets. The 1999 statistics shows that approximately 50% of agricultural imports in the USA were from developing countries, an increase of 38.37% from 1995. There is a growing public and scientific community perception that incidences of foodborne disease are on the rise. However, the high standards can only be effective when they are enforced through an efficient food control system. Therefore, developing countries need to establish food safety management systems that are responsive to recent changes in the international food safety system. The most important issues are how the export sector is coping with new international requirements and how the governments, producers, and consumers are coping with the evolving food safety challenges.

Food Production System

Food production, processing, and marketing systems in developing countries are complex. The food production systems are highly fragmented and dependent on a large number of small-scale producers. The current farm structure constrains farmer's capacity to meet domestic and international food safety standards. Although this may have socioeconomic benefits as large quantities of food pass through a multitude of food handlers and middlemen, the risk of exposing food to unhygienic environments, contamination, and adulteration increases. Literacy rate for most farmers and food handlers in developing countries is low; this limits the number of farmers capable of adopting more sophisticated modern agricultural practices, food hygiene, and good food handling practices necessary to meet more stringent food safety requirements.

However, innovative interventions such as organizing farmers into producer groups, establishing collection centers, contract farming arrangements, and creating public–private partnerships to assist farmers can overcome the farm size constraints. Contract farming and farmer groups' arrangement has been a success in meeting stringent food safety and quality standards in Kenya's fresh fruit and vegetable and India's

 doi:10.1016/B978-0-12-378612-8.00310-3

spices, gherkin, and fruit and vegetable export sectors. This arrangement can also assist farmers in obtaining the capital required to make on-farm improvements, improving farming skills through joint extension provision and assistance in acquiring the required certifications.

During the Green Revolution, use of high-yielding seeds together with chemical intensive agriculture that uses massive quantities of fertilizer and pesticides created diverse effects on soil and environmental contamination. This trend had serious implication on the current international food production system, which emphasizes on minimum use of chemical fertilizers and pesticides, thus posing serious challenges to management of food safety by developing countries. In the past decades, the structure of food production systems has radically changed with many small scale producers venturing into production of export crops with some successes and failures. Major food safety problems occur as a result of poor post harvest handling and storage of food and also due to inadequate facilities and infrastructure such as the absence or shortage of safe water supply, electricity, storage facilities including cold stores, transport networks, etc.

Food Processing Industry

In developing countries, food processing industries range from sophisticated state-of-the-art facilities to small artisanal operations producing food for the local community. The size of these processing units varies from a few large plants to a many small and cottage-scale units with very limited resources for effective technological inputs. In most scenarios, the premises are not equipped to deal with the maintenance of food safety and quality in a scientific and sustainable manner. The challenge for developing countries is how to provide incentives for the effective expansion of these small units so that they adapt better technologies to ensure food safety and quality. Governments often support these small units as they provide employment and generate income for their operators.

Food processors in developing countries also face problems with the reliability and timely delivery of safety and quality raw materials. Raw materials are produced by smallholder farmers who lack infrastructure for their conservation and preservation, resulting in variability in the quality and safety of the raw materials. This calls for greater vigilance by the food processing units and food control activity at all stages along the food supply chain. Food security and safety have synergic effects as technologies used for food preservation also promote food safety both at industrial and household level. Hence, food safety aspects should not be neglected from public health and agriculture policies in developing countries.

Recent Trends in International Food Safety Management

Recent trends in food safety management have had serious impact on management of food safety in developing countries. International food markets provide significant opportunities for these countries to develop their agricultural exports and domestic markets. However, agricultural food products in developing countries are likely to contain food safety risks and encounter sanitary and phytosanitary (SPS) measures as barriers to market access. In addition, extensive media attention and increased awareness on the consequences of food contamination on health have heightened consumer concerns. Food safety and agricultural health standards differ across countries due to differences in tastes, diets, income levels, and perceptions, which influence people's tolerance to these risks. Differences in climate and available technologies (refrigeration, irradiation, etc.) affect the incidence of food safety and agricultural health hazards.

To fully utilize gains from international food trade, developing countries need to overcome these barriers and develop capability to guarantee the safety of their food products. The implications of these trends mean that an effective food safety management system is a challenge but a prerequisite for enhancing food exports from developing countries. The adopted food safety management practices should not only improve their international competitiveness but also heighten domestic food safety awareness. A well-coordinated food safety management system that involves all stakeholders within the supply chain is necessary for prevention of potential risks as experienced in Kenya's fresh horticultural produce and fish sector.

Food Safety Standards and International Trade

The General Agreement on Tariffs and Trade (GATT) international trade rules to protect human, animal, or plant health were so vague that many countries used 'health requirements' as barriers to trade. Changes to the GATT rules embodied in the Uruguay Round of multilateral trade negotiations in 1994 that brought food and agricultural products into the fold of international trading rules addressed these concerns. This lead to the adoption of the Agreement on Application of SPS measures (laws, regulations, and procedures) and an updated Agreement on Technical Barriers to Trade (TBT) that provided an opportunity to ensure fair and efficient international trade based on considerations of equity and fair access to global food markets. These agreements were designed to lay out conditions for transparency, equivalence, regionalization, harmonization, and national sovereignty when countries establish their regulatory measures to ensure food safety, consumer protection, and plant and animal health. The use of unjustified health-related measures as barriers to trade was discouraged unless such measures have science-based evidence and risk assessment principles. Through the World Trade Organization (WTO), there is a scientifically based approach to negotiation and conflict resolution to keep food safety from being an intractable barrier to trade.

The management of SPS measures to reduce food-related health risks poses clear, specific challenges for developing countries which are handicapped by more limited access to scientific and technical expertise and information needed to meet these new requirements. Their difficulties do not appear to influence the international legislative process as most developing countries lack the necessary financial facilitation to participate in the activities of international organizations. The prevailing food production and marketing conditions are

highly fragmented and dependent on a large number of small scale producers. Thus, they are incompatible with SPS requirements such as traceability. Preliminary estimates show significant negative economic consequences of more stringent trade barriers, with millions of dollars lost in commodity trade. Henson *et al*. reported that the number of technical notifications for developing countries to the WTO and its predecessor, the GATT, doubled between 1990 and 1998.

Therefore, any collaborative and development cooperation should support developing countries in the management of food safety for domestic and export markets. With the assistance from international organizations measures to enhance food safety control systems have been implemented in many developing countries with some success, but greater efforts are still needed to allow these countries to effectively build their systems into a sustainable structure.

Strict International Standards

Food safety standards have become a more prominent issue for global trade in agricultural food products. International food trade in high-value food products from developing countries to high-income countries has diversified enormously over the past decades. Owing to increasing consumer concerns, regulators in developed countries have been raising the standards that exporters need to meet to sell on their markets. However, the proliferation and strengthening of food safety and agricultural health standards at international level and in individual supply chains have caused considerable concern among developing countries due to the effect they might cause on the magnitude of the expanded and diversified food exports. There is greater scrutiny of the production or processing techniques employed along the food supply chains.

However, this situation is creating a scenario for competitive repositioning and enhanced export performance of developing countries. Although recognizing that food safety standards (as barrier to trade) can act to impede food exports and prevent new entrants into the high-value food trade, there is a need to view them as catalysts toward improvement of food safety standards for international trade.

Private food safety standards, which fall outside of the WTO, are playing a more prominent role in governing food markets. The costs of compliance, multiplicity of different standards, increasing specificity of those standards, and lack of harmonization among them are major concerns for developing countries. However, evidence indicates that, in many instances, the costs of compliance are less than assumed, especially relative to the value of exports. The growing complexity and lack of harmonization between countries impedes the efforts of developing countries to gain access to potentially lucrative markets in industrialized countries. The World Bank report findings indicated that there is adequate capacity to meet emerging food safety requirements where substantial progress has been made in relation to quality assurance and logistics management. But many developing countries lack the administrative, technical, and scientific capacities to comply with dynamic and increasingly strict food safety standards, presenting potentially insurmountable barriers to the development of high-value food products market opportunities. Several international agencies have been exploring ways to assist developing exporting countries build the necessary national capacity to meet these international safety and quality standards.

The most serious challenges for developing countries have been the costs of failing to meet strict international food safety standards. Evidence of continuing trouble is clearly apparent from Import Refusal Reports issued by the EU and the US. These incidences reported on international alert systems causes drop in price, economic losses due to loss of business, and longer term reputation damage. In 1997, the detection of salmonella in fish and fishery product exports to the EU from India, Kenya, Uganda, and Tanzania were banned. This was attributable to noncompliance of hygiene standards in fish processing plants. However, these countries addressed the hygiene-related problems, and on re-inspection in 2002, approved facilities meeting the requirements of the EU hygiene legislation concerning structure, maintenance, and hygiene, and the countries were added to the list of 'approved' countries.

There are examples of well-organized and well-managed supply chains in developing countries that have maintained or even enhanced their competitiveness and market share during this period of more stringent standards. This is well demonstrated by the case of Thai and Kenyan horticulture (fruit and vegetable) sector, the Kenya Nile perch sector, Thai and Nicaraguan shrimp, and Indian spices. New or more stringent standards also provide a stimulus for investments in supply chain modernization; increased incentives for the adoption of better safety practices and help clarify the appropriate roles of government in food safety and agricultural health management. Significant changes have been introduced in food safety management systems by the leading export companies by adopting and refining HACCP systems.

Evolution in Food Quality Systems

The past decades have witnessed a revolution of food quality systems in food safety management. These include the Good Practices guidelines, HACCP principles, various guidelines for total quality management such as the ISO 9000-2000 set of standards and 'farm-to-fork' strategies. The lack of good agricultural, manufacturing, and hygiene practices in developing countries remain a major challenge for improving food safety both for the domestic and export market. However, in the recent past, there have been efforts to promote good practices inline with GlobalGap or EurepGap. Although the quality management systems remain voluntary, the usefulness of HACCP has been recognized and it is becoming a legislative requirement in many developing countries. A rise in mandatory HACCP for some agricultural sectors (fresh fruit and vegetable, meat, and fishery products) has become a license requirement to export these products. The fragmented and large number of small-scale producers, middlemen, and retailers in the food system poses a big challenge to the management of the 'farm to fork' aspect of food safety for both domestic and export market.

The industries and regulatory bodies in developing countries have also shifted away from the traditional largely reactive focus on end-product testing to process-based quality management (prevention of quality failures before they occur) and

involvement of all personnel in providing customer satisfaction. Process-based regulations shift the primary responsibility for safety from the government to the industry sector, with the government acting as the auditor of the industry's own programs, a move from a 'command and control' approach to one stressing responsibility of private industry actors.

Food Control Infrastructure and Resources

Food regulatory infrastructures in developing countries are inadequate due to limited resources and a multiplicity of agencies under different laws and government departments or ministries (Agriculture, Health, Commerce and Industry, and Fisheries). The multiplicity of agencies makes the management and coordination of control measures difficult. Each agency operates independently to fulfill the function for which it was established. Concerns have been raised that these agencies have no clear vision or precise strategy, and the overlapping of activities and divergences on priorities has a negative impact on the efficiency of the control system. Therefore, there is need for all the food safety activities to be integrated into a single independent and coordinated system. Collaborative planning and effective communication is, therefore, required in the whole food supply chain to efficiently respond to market requirements.

A lack of overall strategic direction means that limited resources are not properly utilized. Food control systems suffer from poorly or inadequately developed compliance policies. Most of the legislations are outdated and have regulatory vacuums in several fields for several products. The goal should be to introduce procedures into the legislation and regulatory texts for preventive control operations and administration. The human resource capacity is limited and not focused in their training. Upgrading of their knowledge and skills in current developments in food safety and quality, food and disease surveillance, HACCP, and risk analysis will enhance their understanding of food safety.

Food control laboratories do not cover the whole country and are limited in scope of testing, are understaffed, few in number, poorly equipped, and lack suitably trained staff. This is accentuated where multiple agencies are involved in food control. Most of the available laboratory equipment are outdated and cannot test to the same level of detection accuracy as in common in developed countries and unable to detect certain emerging sensitive chemicals hazards. Testing for safety of foods derived from biotechnology (genetically modified organisms (GMOs)) is of concern in developing countries. Modern food control systems call for science-based and transparent decision-making process. The preventive approach requires access to qualified and trained personnel in all disciplines. A few laboratories are in the process of modernizing the laboratories to improve their capacity and respond to the increasing demand for the services.

Poor Infrastructure and Services in the Marketing System

Poor infrastructure in developing countries challenges their abilities to meet either public or private standards. Reducing food safety risks from the farm to domestic and export markets is constrained by inadequate infrastructure and facilities, particularly at the farm level, distribution level, and wholesale markets. The infrastructure and facilities in these markets are limited and rudimentary. Waste management and pest control in the markets are very weak. Reducing food safety risks will require significant public and private investments to upgrade the markets infrastructure and services. For regulated markets, this will also require improving the operational and fiduciary in order to build consumer and customer trust.

Food Safety and Domestic Market

Consumers in developing countries face a higher level of exposure to contaminated foods than those in developed countries. The climate in most developing countries favors proliferation of pests, disease, and naturally occurring toxins; the water for cleaning equipments and utensils and processing food are frequently unsafe. There are no regulatory standards, whereas existing standards are poorly enforced. The control of food products on domestic market is essentially repressive and consists of checking that finished products for sale adhere to regulations and fair business practices are respected. This leaves a noticeable void at the level of the production and primary processing stages. Thus, this approach does not always guarantee quality and safety. The rural–urban migration, in past few decades, has contributed greatly to an increase in urban and periurban agriculture. This urban and periurban farming may led to microbial and chemical, especially heavy metal, contamination of food, thus posing a risk to public health.

Owing to poverty, the rural masses do not constitute an important domestic market and cannot stimulate profitable economic activity for the food industry. In most developing countries, increasing incomes, urbanization, literacy, improved infrastructure, and closer ties to global trends, especially during the past decade, have resulted in an expanding domestic consumer-based concerns about food quality and safety. Rapid urbanization and middle class with high income have complicated the situation by changing population's traditional ways of handling food with more people depending on food markets or food prepared outside of the home.

Increased vigilance by non-governmental organizations (NGOs), consumer groups, and local research institutes is also raising consumer awareness and advocacy and spurring action among consumers and policy makers to address food safety risks. These trends have brought increased attention to safety concerns in the handling, processing, and marketing of foods. There is also growing consumer preference for convenience shopping, increased exposure to the media (television, cable, and the Internet), and ownership of durables such as refrigerators, which demand greater efficiency and food quality and safety standards in the supply chain.

There is need to shift to the modern control system, which is characterized by reduction of analyses and their cost to the regulatory bodies. The industry takes on the responsibility of self-inspection and the government replaces inspection of the finished product with validation of industry self-inspection and self-evaluation systems. Some analyses can be carried out within the framework of voluntary self monitoring by the industry. The control system should set up permanent dialogue with industry representatives in order to inform them of

their obligations and changes in regulations. However, export products follow a codified methodology essentially dictated by the requirements of the export market.

Street Foods

The rural–urban migration in developing countries has contributed to an increase in street vended, ready-to-eat, and convenience foods. Studies in developing countries have shown that up to 20–25% of the household food expenditure is incurred outside the home and some segments of the population depend entirely on street foods. As one of the consequences of rapid urbanization, millions of populations largely depend on street foods for their daily sustenance. In most developing countries, street food vendors are an important component of the food supply chain. Being reasonably priced and conveniently available, street food satisfies a vital need of the urban population. These ready-to-eat foods and beverages are prepared and/or sold by vendors or hawkers mainly in streets or other convenient public places such as around places of work, schools, hospitals, railway stations, and bus terminals. Food safety is major concern within the street foods supply chain. These foods are handled, prepared, and sold under unhygienic conditions with limited access to safe water, sanitary services, or garbage disposal facilities. Hence, street foods pose a high risk of food poisoning due to microbial contamination, improper use of food additives, adulteration, and environmental contamination.

Foodborne Diseases and Surveillance Systems

Foodborne diseases are a problem in developing countries. Food is prepared under unhygienic conditions at household and food service establishment level. This results in foods frequently being contaminated with foodborne pathogens and thus major cause of diarrheal disease. In developing countries, infectious diarrhea is the second leading cause of death, especially in children less than age of 5 years, after respiratory diseases. The cause of diarrheal diseases has traditionally been attributable to untreated water supply and unhygienic sanitation. It is widely assumed that many pathogens associated with infectious diarrhea are transmitted through the fecal–oral route. Efforts to prevent these diseases have been focused on and sometimes limited to improving water supply and sanitation. However, data show that food, being a favorable medium for growth of microorganisms, is the most important factor in the transmission of diarrhea illnesses. In developing countries, the role of food as vehicle for acute infectious diarrhea and in the epidemiology of infectious diarrhea diseases are ignored and preventive measures do not adequately include food safety considerations. Many outbreaks associated with foods are sporadic cases and often go undetected. In developing countries, risks associated with food contamination and need for improving food safety are frequently not included among strategies for the prevention of diarrhea illnesses by public health authorities and other agencies. In majority of these countries, attention given to foodborne illnesses is more reactive rather than proactive.

Most of the developing countries lack or have weak surveillance system. Investigations into foodborne disease causative factors and magnitude of exposure are inadequate. This results in significant underreporting of foodborne illness. Available data are not well documented and analyzed during risk management. This often leads to wrong decision making and thus reoccurrence of foodborne illness with negative impact on public health and food trade. The management of infectious diarrhea in these countries is the responsibility of public health, whereas food safety is associated with food regulation and food control agencies under different ministries. This results in food safety receiving marginal attention from public health sector. In the past few decades, food safety has been recognized within the agriculture and trade sectors, instead of it being at the forefront to ensure that human health is adequately considered in food safety policies and standards.

Policy and Regulatory Environment

Because of low consumer awareness, the private sector engaged in food production, processing, distribution, and retailing in developing countries has not taken the necessary steps to improve the quality and safety of food products. The government is responsible for ensuring food safety through enacting and enforcing legislation and setting standards. Therefore, addressing food safety issues in developing countries requires the adoption and enforcement of more appropriate food safety policies, legislation, and standards suitable to local food risk conditions and preferences and consistent with international requirements.

Weak Extension Systems

The agricultural extension systems are very weak and have not effectively focused to the changing needs of food safety and agricultural health and market safety requirements. Food safety concerns have been partly addressed through the integrated pest management programs. Farmers primarily depended on personal observation or on other farmers for information about food production and post harvest practices and pesticide use. The weakly coordinated research at the national and international level further increases the difficulty of ensuring effective research–extension–farmer linkages at the national level. Private extension provision (fee for service) is emerging within farmers producing high-value export crops. There are an increasing number of input suppliers, traders, contract buyers, and exporters who provide extension services to farmers as an integral part of their trading arrangements.

Consumer Knowledge and Awareness

The level of knowledge and awareness on food safety issues among the domestic consumers is still very low and in fact their main concern is more on food security rather than food safety. Majority of people in developing countries have low incomes and are faced with a big challenge of limited choice, a situation worsened by the limited supplies of most essential food categories during seasons of limited supply.

Inadequate Food Safety Standards and Poor Enforcement

The domestic food safety standards need to be aligned with international standards. However, for some commodities, it may not be possible to align domestic standards with international standards as there are no established international standards. In these instances, conducting research is important to set appropriate standards for the domestic market. Some national bodies provide third party certification quality certification scheme as an assurance of quality and safety.

It has been recognized that the gains in improving food safety practices in the export sector should spillover into the domestic market. However, because majority of production is consumed in the low-priced domestic market, farmers do not see any advantages for altering their production practices. Until domestic consumer awareness and willingness to pay for improved food safety becomes more widespread, it is unlikely that addressing food safety concerns will become standard practice. International experience shows that modernization of the food retail sector is an important driver for change not only in the structure of production and wholesale marketing of produce but also in fostering adoption of improved food safety standards.

Lack of Proactivity in Addressing Food Safety Issues

Domestic food safety scares and problems in agro exports reveal absence of proactivity within developing countries in addressing food safety concerns. Several factors contribute to this. In the case of agro exports, the emerging SPS measures and international standards are widely viewed as not scientifically based and as representing unfair 'barriers to trade.' These measures are viewed as efforts to protect foreign farmers or processors from competition or are being fueled by unreasonable consumer fears in developed countries and improved technologies for detecting hazard. The approach of developing countries has been to try to negotiate away the problems with trading partners and failing to address the various measures in international standard setting. Insufficient attention has been devoted to monitoring the requirements of standards, interpreting their implications, and using current and anticipated requirements as catalysts to upgrade existing operations and strengthen supply chain management.

This absence of proactivity has meant that developing countries either have to adopt a 'defensive' strategy by avoiding markets with more stringent food safety and agricultural health standards or have to launch into a fire-fighting mode when faced with potential disruption or loss of trade due to noncompliance with standards. The absence of proactivity is well illustrated through examples of problems faced with exports of fish products to the EU from Kenya and India in the late nineties. In both cases, although there were signs of potential problems for a considerable period of time, the food safety problems were not given serious attention until these countries were faced with a ban crisis.

Collective Action

Cases of successful experiences in fruit and vegetables, fishery, and spices sectors using collective action have highlighted its importance within the food sector. It is aimed at promoting awareness of food safety matters, finding solutions to emerging challenges, providing a degree of self-regulation, and reducing government agencies enforcement roles. Joint and shared efforts by the government and private sector is needed in better risk management, promotion and adoption of good practices, greater collective action, and some targeted public investments. Although there are many critical regulatory, research, and management functions that are carried out by governments, the private sector also has an important role in the actual compliance with food safety requirements.

Technical Assistance and Role of International Agencies

The need for technical assistance in strengthening food control systems in developing countries is well recognized. Both the SPS Agreement (Article 9) and Technical Barrier to Trade (TBT) Agreement (Article 11) specifically refer to need to provide technical assistance to developing countries. Food and Agriculture Organization of the United Nations (FAO), United Nations Industrial Development Organization (UNIDO), and World Health Organization (WHO) are the main international agencies involved in food quality and safety technical cooperation programs with developing countries. Such assistance is in areas of processing technologies, research and infrastructure, establishment of national regulatory bodies, etc. In particular, developed countries are required on request to provide technical assistance to the exporting developing countries to enable them to meet their WTO/SPS/TBT obligations. This opportunity to access technical assistance under the WTO/SPS/TBT Agreements has not been fully utilized by developing countries. Technical assistance in the food control area may also be obtained through the World Bank and bilateral donor agencies. Access to such funds is dependent on the priority that developing countries attach to strengthening their food control systems as reflected in their national development plans.

Conclusion

The challenges for ensuring food safety in the domestic and export food market in developing countries still remain large. Improving domestic food safety in developing countries, for domestic market or export trade, is hampered by a number of structural, policies, institutional, technical, and cultural challenges. Addressing these food safety concerns will require adoption of appropriate legislation, strengthening capacity to enforce laws, promoting adoption of good agricultural, manufacturing, and hygiene practices, greater collective action, and some targeted investments. Implementing these actions will require joint efforts by the government and private sector. The challenge for the future should be to adopt a more strategic rather than crisis management approach. This will be essential to ensuring the sustainability and cost effectiveness of these efforts. Hence, there is a need for continued technical assistance and dissemination of relevant information to developing

countries to help them to meet the ever-increasing and more complex challenges posed by international markets.

PUBLIC HEALTH MEASURES

Challenges of Industrialized Countries in Food Safety Management

LM Crawford, USA

Glossary

Apertization French term for canning; preservation of food by sealing in cans or jars.
Organoleptic Inspection of food through the use of the five senses.
Robert von Ostertag German veterinarian who devised the organoleptic system of food inspection.
Salmonella A bacterium that is one of the leading causes of foodborne disease in humans and animals.

Introduction

Industrialized countries vary greatly in food safety system's organizational structure and effectiveness. This article is designed to provide some common ground on the essentials of a national food safety program. Inherent differences in the physical characteristics and the culture of different countries complicate a precise harmonization of food safety measures and requirements. Nonetheless, international trade in food requires that there be a core set of rules and procedures that trading partners hold in common. Moreover, scientific consensus on the importance of certain key requirements demands a certain degree of agreement between nations.

Modern food safety had its origins in international trade. The German approach to food safety was to establish rules. This grew out of the success of their Bier und Brot (beer and bread) law which was effectuated in the thirteenth century. That law forbade additives and demanded pure water to be used in food manufacture.

In the 1880s and 1890s, a brisk trade in pork was established between Germany and the US. This led to regulations from the US Department of Agriculture (USDA) requiring inspection of US meat consigned to international destinations. Ironically, there was no such law requiring inspection of meat destined for the US market.

The Germans were primarily concerned about *Trichinella spiralis,* the causative agent of trichinosis which was prevalent at that time in pork. And in 1900, Germany passed into law the Imperial Law Concerning the Inspection of Meat and Food Animals. This proscriptive law set the standard for similar laws in the Western world. Most notable among these was the US Wholesome Meat Act of 1906.

More important than the laws was the method of inspection that fulfilled the dictates of the Imperial Law. Robert Ostertag was a Renaissance man who was a veterinary parasitologist at the Berlin School of Veterinary Medicine. His 1904 book, *Handbook of Meat Inspection*, which described the organoleptic food inspection system, remained the standard throughout the world until comparatively recent times. In fact, this system which involved the use of the five senses in the systematic inspection of food remains the standard and the basis of food inspection in much of the world.

In the US and certain other developed nations, the food inspection system has embraced, to varying extents, the hazard analysis and critical control point system (HACCP). Critical control points are points in the food production process that can potentially contaminate food with pathogenic microorganisms. Many experts believe that HACCP is sufficient as a food control system without the addition of the organoleptic system. The US meat and poultry inspection system, however, includes elements of both systems.

This article then addresses the challenges inherent in a national food safety program in the industrialized world. The discussion of those challenges must perforce begin with the acknowledgment that there is no failsafe or perfect system. This acknowledgment recognizes the unpredictability and the biological difficulty of controlling, with precision, foodborne pathogens. Societal and political considerations will likewise be considered. Chief among these are public expectations of food safety programs.

Essentials of a National Food Safety Program

The first essential is a strong food safety law. Laws are enacted in different manners throughout the world. Some are dictated, others are the product of a more or less democratic process. Ideally such laws will have been the subject of serious debate and careful planning. The result of such a process results in a law that represents the national conscience as well as the expectations of the people. With a comprehensive and workable statute, the leadership of the national food safety program will have a blueprint for accomplishing his/her mission. Not only that, the political leadership of the respective country will have approved and ratified the law. Moreover, the law should have enforcement provisions describing the responsibilities of food

producers, consumers, and the government. Also, the law should provide legal authority to take punitive action along with penalties for violations of the law. The strength of the law reposes in its specificity and the appropriateness of the prescribed penalties.

The second essential of a national food safety program is the presence of a state-of-the-art scientific laboratory system. Food safety concerns can be reduced to two categories: microbiological contamination and chemical contamination. Control efforts are thwarted if detection methodology is inadequate. This frustrates monitoring and surveillance of the food supply and it can invalidate enforcement actions. It is difficult to police the food supply if you cannot detect what is in it. A modern food laboratory system is expensive and it requires expert personnel. The quality of these laboratories varies from country to country and this complicates communication between trading partners with the end result being factual disputes that could be avoided.

The third essential element is having a staff that is adequately trained and credentialed. Food safety is essentially an applied scientific endeavor. The scope of that endeavor is broad and the required knowledge base is demanding. The key to proper staffing lies in determining the required disciplines. This inevitably invites comparisons between food scientists, chemists, biologists, veterinarians, microbiologists, and physicians among others. Experience has shown that access to the expertise of all these is needed. Probably the most versatile discipline at the baccalaureate or bachelor's level is that of food scientist. The food science curriculum presents some exposure to chemistry, microbiology, statistics, and food manufacturing. It is currently popular to have the head of food safety be a physician or someone else with a doctoral degree. This is probably good if the incumbent has experience in the field of food safety. To put it differently, the training of a food safety staffer largely refers to their collegiate training and experience in the field of food safety. Credentials can be said to represent validation of expertise through graduate training in related fields, awards, honors, and the like. The presence of a thoroughly trained and experienced staff is mandatory in order to establish authority and to effectively carry out the responsibilities of national food control. Such a staff is difficult to maintain, expensive, and terribly hard to retain, but it must be done. Errors in judgment, mistakes in regulatory determinations, and unimpressive job performance will effectively invalidate the performance of a food safety agency. The agency does not have to be a university but it must, nonetheless, be competent.

The next essential of a national food safety system is to have an adequate number of personnel. The strongest law and the greatest commitment cannot make up for a deficiency of personnel. The level of food protection will dangerously decline if a country does not have enough people to get the job done. Proper staffing numbers should be determined using practical work efficiency models taking into consideration travel logistics and work product success rates. No two countries that have populations of 4 million will require the same number of personnel. Notwithstanding that, exchange of staffing information and discussion of staffing adequacy between nations can be a useful starting point in determining the optimal staff size. Most national food safety agencies pride themselves in having cordial and productive relationships with counterpart organizations in other countries. These relations not only can lead to useful models but also are important in regulating as well as encouraging international trade.

Fifth and finally, it is essential to have the optimum organizational structure. First and foremost, the person in charge of food safety in a national government must have the authority to make public health decisions. And that person should report to a scientist or physician if at all possible. Experience has shown that the best locus for a food safety agency is the department of health, not agriculture. Decisions made by the food safety chief are often matters of life and death. They must not be dealt with lightly. If the chief is not in a position of authority, then the leadership of the food safety agency can degenerate into a committee which is a situation incompatible with public health. Of course the minister of health or similar leader should and must have the prerogative to overrule the food safety official and to relieve him or her from office if necessary. Agriculture is an improper location for food safety not so much because agriculture departments must promote farmers, but because ministers and subministers often have no food safety or disease experience. The food safety agency must be organized economically in that the fewer leaders the better. Ideally, food safety agencies should be divided into inspection and enforcement branches. Therefore, the core administrators should be the Chief of Food Safety, the Deputy Chief for Food Inspection, and the Deputy Chief of Food Safety Enforcement. The names and the titles may of course be altered consistent with national usage in governments. A third tier of leadership can include assistant chiefs for finance or budget, outreach, political affairs, etc. The assistant chiefs should be staff officers and not line officers. Further branching of authority may be incorporated into the organization but should be kept to a minimum.

The Ideal Inspection System

HACCP is, at the present time, the state-of-the-art system for food safety management. This is because HACCP focuses on preventing contamination of the food supply with disease causing organisms. The Ostertag or organoleptic system focuses on detection of contamination after the fact. If the contamination has already occurred, it is too late to prevent foodborne disease. Even continuous inspection will overlook virtually all contamination. The organoleptic system was designed to look for the main food safety concern of that day–parasites. Today, the principal food safety concern is disease causing microorganisms that cannot be seen by the naked eye. The visible manifestations of bacterial and viral infection–pus, hemorrhage, swelling, and discoloration can sometimes be seen but usually are not. Thus, the organoleptic system is outdated and inadequate.

HACCP is a systematic approach to the identification, evaluation, and control of food safety hazards. The Pan American Health Organization (PAHO) describes HACCP, simply, as a preventive system for assuring food safety. The PAHO manual on HACCP further elaborates: (HACCP) is based on a common sense application of technical and

scientific principles to the food production process from field to table. The principles of HACCP are applicable to all phases of food production, including basic husbandry practices, food preparation and handling, food processing, food service, distribution systems, and consumer handling and use.

Scientists, the world over, always seek to improve public health and therefore the tools of public health including HACCP. The question is what is beyond HACCP. Future improvements may be marginal given the elegance of the HACCP system. Such improvements may or may not emanate from HACCP.

The hazards that HACCP is designed to prevent fall into two categories: microbiological and chemical. That is to say, HACCP only exists to aid in the control of these contaminants. And, admittedly, neither HACCP nor any other system is perfect. Therefore, future changes in HACCP or development of a new system will be dependent on scientific developments that point the way to a new system or improvements in HACCP. Because HACCP is, in fact, a system and not a scientific development, the basic structure of HACCP may not be improved on. What will change will be the science of contaminant detection and the means of reducing or destroying contaminants.

Elucidation of the genome of various pathogenic microorganisms could lead to better systems of detection and control. Transgenic microorganisms could be developed that target and destroy pathogens. Transgenic organisms likewise could be created that scavenge chemical contaminants and microbial toxins.

Decontaminants of both pathogens and chemicals could be developed that are more effective than today's armamentarium. Findings borne out of serendipity could vastly improve control of both categories of contaminants through mechanisms not yet discovered.

But in fine, all these imagined break-throughs would not force a change in the fundamental structure of HACCP. Thus, its status as the ideal food safety system may not change in the foreseeable future.

The Ideal Enforcement System

Ideally, the enforcement system must be grounded in a strong, enforceable national food safety law. Enforcement cannot be based on borrowed authority. The law must explicitly be designed to ensure the availability of safe food to the extent possible. Weak laws may be successfully challenged in court resulting in disarray in the food safety enforcement system. Also, it is important to design the law correctly the first time. Amending the law based on experience is time-consuming and difficult to accomplish.

Serious enforcement requires strict adherence to the national food law. This requires well-worded regulations (rules) and clearly written directives or guidances to the regulated industry. These likewise should be sensible, defensible, and enforceable. Public confusion over the requirements of the law and the resultant regulations leads to an untenable situation which can only lead to an erosion of authority and an inability to accomplish the objectives of the enforcement division.

Enforcement personnel must be well-trained. There likewise should be continuing training and refresher courses in their duties and responsibilities. The morale and enthusiasm of enforcement personnel is bolstered by strong administrative support and adequate resources to accomplish the mission.

In some countries, the effectiveness of enforcement is weakened by uncertain authority between national, state, and local authorities. Optimally, the national food safety agency should have clear authority over state and local authorities. If a regulated product is not traded nationally, authority may devolve to subsidiary authorities. In order for effective communication to occur between state and national authorities, comprehensive written agreements should be constituted. These, commonly known as memoranda of agreement, declare the articles of delegated authority as well as the expectations of the specific parties.

Facing Unexpected Food Safety Challenges

The Centers for Disease Control and Prevention in the US estimates that there are 5000 deaths, 76 million illnesses, and 325 000 hospitalizations from foodborne disease each year in a country with 300 million people. This means that foodborne disease is not rare and is a major problem in a country that is considered highly developed. This, then, is the expected food safety challenge – a high level of debilitating disease that materially affects US citizens. The unexpected challenge comes in the form of major outbreaks that often have no clear source and which result in some serious illnesses, deaths, and even permanent injury. And the US is not alone among developed nations that continue to have unacceptable levels of foodborne disease.

The major outbreaks of food related disease affect public opinion and often bring about changes in food safety procedures. Outbreaks are generally a small fraction of the actual number of illnesses in a given country and the outbreak itself can be surprisingly small. Nonetheless, major outbreaks receive enormous publicity and political interest. A cursory review of some of the major outbreaks in recent US history follows.

The year 1985 was the year of perhaps the two most important food disease outbreaks. First came the Jalisco cheese outbreak in Southern California. The causative agent was *Listeria monocytogenes*. There were 142 cases and 47 deaths. Business at the cheese plant had increased dramatically. To meet the demand, the company overwhelmed the Pasteurization equipment with raw milk and thereby the cheese became contaminated with *Listeria*. Next came the great Chicago milk outbreak. The Centers for Disease Control and Prevention (CDC) estimated the total number of illnesses in six Midwestern states from 16 000 to 200 000. The numbers of deaths were estimated from 2 to 7. The milk was placed in large cooling vats one of which had a small tear in the inner lining. Milk leaked into the space between the inner and outer lining where it remained for an extended amount of time contaminating each new batch of milk with the *Salmonella typhimurium* that was proliferating in the tank.

In 1993, a fast food company in the Pacific Northwest introduced a large new hamburger named the Monster Burger.

Although never conclusively proved, some of the Monster Burgers may not have been thoroughly cooked. *E. coli* 0157:H7 caused the deaths of four children and sickened hundreds of others.

1994 was the year 3000 fell ill in 41 states subsequent to eating a particular brand of ice cream. A tanker truck was used to convey liquid, raw eggs on one leg and pasteurized ice cream on the return trip without cleaning and disinfecting the truck. The eggs were contaminated with *Salmonella* which contaminated the final product – ice cream.

Salmonella contaminated irrigation water in Mexico was found to have contaminated serrano peppers that were used as ingredients in various US foodstuffs. This caused at least 1017 illnesses, 203 hospitalizations, and at least one death in the US in 2008.

Salmonella newport contaminated peanuts were sold as an ingredient in numerous other foods in 2009. Nine people died and an estimated 22 500 were sickened. The vector of the pathogen was thought to be rodents that had easy access to the stored peanuts.

In all these devastating outbreaks, there was a simple cause that common sense and vigilance would have prevented. As a result of obvious disregard for public health, thousands were made seriously ill and many died or were hospitalized. Public confidence in the food supply has eroded, and millions of dollars have been spent on food safety by government, industry, and the public.

Some years ago, the Food Safety and Inspection Service of the US Department of Agriculture produced a film titled, The Anatomy of a Recall.

The essence of the script was that it is much better to prevent a recall than it is to go through one. If large amounts of food have to be recalled and consumers must be subjected to the publicity of doubt, fear, and accusation centered on something so basic to the diet as legumes, meats, nuts, eggs, etc., the system has failed and much harm will ensue. Each food manufacturer, each consumer, and each government regulator must be sharply focused on food safety on a continuing basis. This must start with the leadership of all affected organizations. Today, the officers of most food companies in the industrialized world receive regular media training. They also should have regular food safety training. The previous narrative on historically significant food safety outbreaks does not mention that many of the companies affected by these outbreaks no longer exist or that their demise was directly due to the outbreak. Sadly, many of these experienced in their existence, only one food safety outbreak and it was the one that put them out of business.

If a recall is required, it means that the system has failed and that the consequences will be great. The company has failed to produce safe food, the government has failed to detect or prevent unsafe food from reaching the market, and the public has an obligation to return the unsafe food.

Public and Political Considerations

There can be little doubt that food safety is an international movement. In the twentieth century, citizens found out about food safety problems from newspapers, television/radio, and books. The twenty-first century is the century of the internet. Food safety information reaches the public instantaneously. Major foodborne disease issues have convicted the public to demand an absolutely safe food supply. The fact that this is not practically possible has not dissuaded the people. Unexpected, new food safety problems have been mainly responsible for the current profound concerns.

All principal paradigmatic developments developed in the latter part of the twentieth century. Cardinal among these is bovine spongiform encephalopathy (BSE). No foodborne disease has ever struck such a fear and it was such a startling development. Second has been genetic engineering of food and food animals together with cloning and bovine somatotropin. Although it is obvious that the manipulation of genes is not a foodborne disease and that these technologies are safe, the newness and the novelty have caused concerns about the food supply that may exceed those of BSE. Likewise, the spate of a group of pathogens not generally familiar has wreaked havoc with public confidence in the food supply. *E. coli* 0157:H7 is obviously a mutant of *Escherichia coli* that causes a potentially fatal form of hemorrhagic enteritis in man. Particularly alarming to the public is the fact that this organism appears not to cause disease in the carrier species, cattle. *Salmonella enteritidis* which was found in the 1970s and 1980s to have adapted to the oviduct of laying chickens again causing no disease in the layer but causing serious enteritis and sequelae has further concerned the public. *Campylobacter spp.* likewise was found in the 1980s to be a serious pathogen of man and to be present in a significant percentage of chickens and to be a factor in the development of Guillain–Barre disease in humans. These developments, all occurring in the space of a quarter of a century, have been one of the reasons for the increasing interest in food safety in industrialized nations.

Beleaguered officials in government and industry have generally tried to explain the aforementioned developments by apologizing for their own missteps. Certainly legislators have blamed government and industry for most of the present day food safety problems. The language of food safety should not be so much tinged with recrimination. Although there are miscreants in food manufacturing and production, the vast majority will do everything possible to prevent food safety outbreaks. The answers no doubt lie in science. As surely as mathematics is the language of science, then science must be the language of food safety. For example, a Canadian vaccine company has developed an *E. coli* 0157:H7 vaccine for cattle that may prevent bovines from being the carrier of this organism thus preventing infection in humans. Thus, a new scientific development may accomplish what disinfectants and antibiotics and inspection and enforcement, and not even HACCP could accomplish. Research should and must be the future of foodborne disease and therefore food safety itself.

The Food Safety Imperative

Food safety is located in various different departments of government throughout the industrialized world. But food safety is special. It should be placed among agencies that deal with public health and the emphasis should be on the human health consequences of food safety that is to say on foodborne disease.

This is because the department that houses food safety must perforce ascribe to the food safety imperative. This dictum embraces the following principle: Food safety is a public health undertaking and all its efforts are dedicated to preventing disease in human beings. It is important that the food safety imperative be the working credo of food safety agencies. This is because its employees and the public it serves must know what the agency's mission is and where its priorities lay. Nonpublic health functions should be looked on as distractions. Therefore, the first great challenge is to have the food safety agency located in the national health department.

The second great challenge is foodborne disease itself. Food safety agencies, with guidance and input from the public it serves, must rank the foodborne diseases in order of priority. This must be done analytically using the science of risk assessment. If the greatest risk to the population is *Listeria*, then the most effort should be expended in counteracting *Listeria*. Such a ranking should place the organism at the forefront of inspection, research, and outreach priorities. Also, the citizens should be aware that the food safety agency had targeted *Listeria* as its lead priority and that *Listeria*, in the view of the agency, represents the greatest risk to the population as a whole.

The third challenge is chemical contamination. As late as the 1980s, concerns about chemical contaminants were greater than for microbiological concerns. But the era of pesticide and antibiotic residues in food has diminished and in the current era, industrialized countries are more concerned about microbiological hazards. This concern must not be allowed to overwhelm concerns about chemical hazards. Many of the same historical concerns about chemicals still are troublesome. To be sure, mercury levels in fish remain a potential public health threat in most countries. Heavy metals can be found in much of the food supply at various levels. Newer chemicals are being introduced to the environment on a regular basis with little concern for food safety implications. Moreover, older chemicals become of great concern because of new toxicological findings. A case in point is the plasticizer Bisphenol A or BPA. Although it has been known to have estrogenic properties for decades, it is now suspected of being a fetal toxicant and more. Acrylamide, a compound produced by some cooking procedures now appears to be more toxic than originally believed. Diacetyl, used in the manufacture of popcorn and certain other foods has been shown to cause serious lung disease under some circumstances. Because diacetyl, BPA, and acrylamide are of human health concern, efforts should be underway to determine the threat that food contamination might play, but there appears to be little research in this particular area.

Fourth in this cascade of challenges is environmental contamination. Degradation of the environment can affect the food supply both directly and indirectly. The greatest concern now is, and always has been, sewage. Fecal contamination from both man and animals can introduce pathogenic microorganisms and parasites to the food supply. Population increases, water shortages, floods, and many other factors affect the presence and location of this pernicious contamination. Population increases and the source of the food are major contributing factors. Other forms of environmental contamination such as industrial run-off remain of concern.

The fifth great challenge is international trade. Increased food trade is a good thing that it inevitably results in better nutrition over the seasons for most countries and it is a useful source of revenue for individual countries. Some countries, such as South Korea, import most of their food supply, so food trade is essential. Unchecked international food trade can nonetheless lead to adverse effects. Apart from the obvious and omnipresent threat from bioterrorism, travel time and conditions aboard vessels of conveyance pose the risk of spoilage and microbe proliferation. Rejection of food shipments at ports of entry can lead to port shopping and reentry to the country that rejected the shipment as well as to other countries. In these instances, adulteration of the food with toxic substances that are used in an attempt to prevent spoilage or to mask the odor of decomposition can occur and sometimes creates a hazard greater than the initial concern. Trans-shipment of unfit food through one or more countries sometimes results in confusion about the country of origin. These examples bespeak the need for regulation of international food commerce. It is the dual responsibility of the country of origin and the recipient country to ensure that foodstuffs from other countries are safe.

Challenge number six is the further development of food safety science. In industrialized countries, there is often a more or less well-developed scientific body of knowledge in food manufacturing, sensory physiology, food preservation, and the like. But institutes of food safety medicine and food public health are rare and if they exist, they are often underfunded. Among the many reasons for this is the constellation of disciplines that are requisite in understanding and preventing foodborne disease. Cardinal among the required disciplines is medicine, including veterinary medicine. Food science, microbiology, virology, toxicology, parasitology, and others all constitute the necessary body of knowledge and experience in addition to medicine. The CDC in the US is well known and respected for its epidemiological expertise and diligence. But, CDC is not a basic research institution. Other federal and private research programs are limited in food safety basic research programs. Notwithstanding, the microorganisms continue to evolve and to develop new and different means of circumventing natural defense mechanisms and external control programs. Each industrial nation must have a well-funded and well-planned program in basic food safety research. It is well to remember that before the 1970s, *E. coli* 0157:H7 was not known to exist. *S. enteritidis* had not been found in chicken eggs. The role of *Campylobacter spp.* in foodborne disease and in Guillain–Barre syndrome was poorly understood. HACCP was unfamiliar to the food industry. Control programs for *Listeria* and most of the zoonotic foodborne organisms were inadequate. And virtually every control scheme for pathogenic foodborne organisms was developed after outbreaks in humans. That is to say many food control systems are retrospective and the ability to predict the next serious pathogens in the food supply is elusive. The means of dealing with foodborne disease lies in research. Research that is targeted toward existing disease and the pathogens to come.

Conclusion

The current annual CDC estimates of the incidence of foodborne disease is 5000 deaths, 325 000 hospitalizations, and

76 million illnesses in the US. If these estimates are correct and if they are true in similar countries, foodborne disease is uncontrolled and a leading cause of sickness in the industrialized world. Moreover, current control programs, including HACCP, should be regarded with suspicion.

It is generally accepted that HACCP is the most practical and efficient food control system extant. In point of fact, practical and efficient imply a certain compromise. HACCP is neither absolute nor failsafe. All food processed under HACCP is reasonably safe but calamities do happen.

What is beyond HACCP? No one knows at this point and practically no research is undergoing on systems that would potentially be superior to HACCP. Few public health programs are conducted with such disregard to the possibility of progress. In cancer research and in neurological research as well as in genetic disease of all sorts, the understanding is that control programs are but a first step on the steady pathway to eradication. HACCP experts should be impatiently looking to replace HACCP with a system that is more effective.

Often, great progress in public health programs has been preceded by technological break-throughs such as was the case with Pasteurization and with water purification. But two of the greatest triumphs in foodborne disease prevention occurred as a result of national competitions. When Napoleon needed a method for preserving food for his troops, he heavily funded a prize to the first person to come forward with an effective method. History was made when a baker, Nicholas Apert, presented the Emperor with apertization (canning). When the National Aeronautics and Space Administration (NASA) of the US wanted a food safety system for space travel, they invited applications for a major grant designed to stimulate the development of such a system. The Pillsbury Company under the leadership of Howard Bauman got the grant and developed HACCP. Perhaps it is time to fund a grant for the development of the next generation of food safety systems.

In closing, it must be said that the control of foodborne disease is a public health undertaking that affects every man, woman, and child on this planet. The food safety imperative is guided and energized by the simple truth that it should be the right of all people to expect and depend on a safe and nutritious food supply. Let no one believe that the food safety imperative has been accomplished. There is much work to be done.

PUBLIC HEALTH MEASURES

Fundamentals of Food Legislation

D Jukes, University of Reading, Reading, UK

Key Objectives

When a society believes that it needs protection, it is usual for the national government to respond by passing legislation, which provides that protection. Early laws on food control can be traced back many centuries, but the modern concepts of food law are mainly based on ideas developed in the mid-nineteenth century. With industrialization and urbanization, the food producers and consumers had become separated not only in distance but also in personal contact. This led to widespread abuses that even affected all urban dwellers, including the elite. At the same time, advances in science, including microbiology and chemical toxicology and analysis, made it clear that the food supply was frequently contaminated and often harmful. Action followed and led to the adoption of general food laws – for example, the UK Act of 1860 is claimed to have been the first general pure food law in the English-speaking world.

Today with continuing advances in food science and technology and the rapidly growing urbanization of much of the world's population, the food supply chain has become increasingly complex and globalized. Although the advances have enabled most people to enjoy a regular and varied food diet, many consumers however are still reluctant to accept certain aspects of modern science and technology in the food supply. The rejection in some parts of the world of irradiated and genetically modified foods are clear examples where the advances have not only met consumer resistance and the legislators attempt to adopt controls which assure safe food but also allow clear consumer choice.

Food legislation is only one part of the system used to try and provide consumer protection. While the scientist or technologist may be focussed on the content of the legislation – what level of additive is permitted, for example – the effective implementation of a national food control system depends on the smooth and efficient operation of various elements. A modern and well-drafted set of legal documents may appear to be sufficient but in practice, without an effective administrative team within government, without a committed and professional enforcement team, and without the support of a well-resourced laboratory service, the legislation is likely to be ineffective.

Food law can usually be identified as belonging to one of two key objectives of protection – food safety and food quality. A third objective, the use of legislation to enhance the nutritional quality of the diet is a more recent development. These are indicated in Figure 1.

Food Safety

To protect consumers from adverse health effects, legislation usually places responsibility on the food suppliers to ensure that the food is safe. To provide for ease of enforcement, detailed legislation has been developed to provide clear statements of what constitutes safe and unsafe food. Examples of these include controls on the hygiene of production and distribution, limits on the levels of chemicals in the food (whether added on purpose or found as contaminants), approval systems for the control of new processes (e.g., food irradiation or genetically modified foods), and specifications for food-contact materials, including packaging.

Food Quality

Food can be perfectly safe but may not be satisfactory. As an example to illustrate the difference, consider a container of milk. The milk may have been subject to detailed hygiene controls and may be entirely safe for consumption. However, if during the collection and/or distribution of the milk, some water had been added, but the milk was still being sold as pure milk, the consumer buying the milk would in fact be paying for a mixture of milk and water. If the product was sold as milk, then the consumer is not only being defrauded but also deprived of nutrients. Food law is therefore developed to provide consumers with protection in the compositional quality of the food they are buying. The manner of these controls varies and different approaches are possible.

- At one extreme, it is possible to provide detailed specifications for a wide range of food products. Manufacturers are then required to only produce products meeting these legal specifications. This method, sometimes termed as 'recipe law' ensures that consumers can be confident that the foods they buy will meet nationally approved standards. However, this approach limits the manufacturers, stifles product development, and restricts consumer choice.
- At the other extreme, it is possible to allow manufactures total freedom to manufacture any food product (a *'laissez faire'* approach), but for the legislation to require fully informative labeling so that the consumer can then decide whether or not to buy the food based on the information on the label.

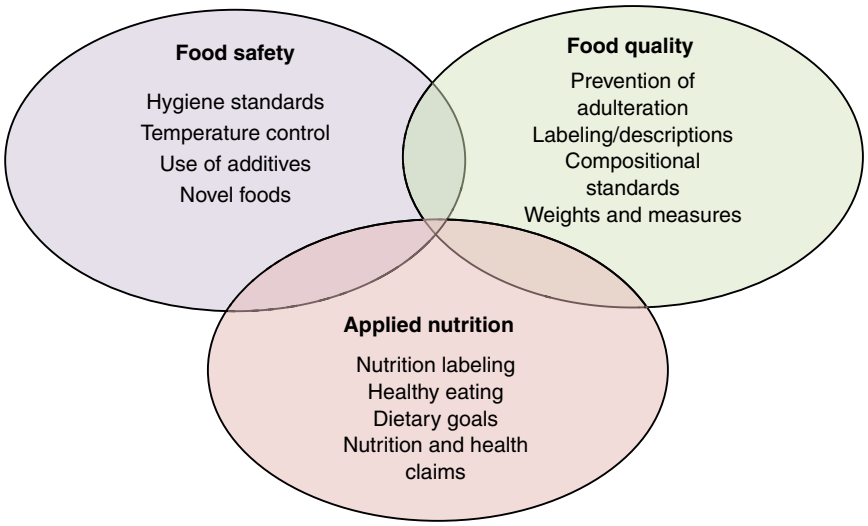

Figure 1 Areas of protection by food legislation.

In practice many countries have adopted a combination of these two approaches. It is common to provide a number of controls based on the product standards for products which are considered of importance to the national diet – for example, bread and milk. When manufacturing other products, manufacturers have much more freedom, but must comply with the labeling rules. The balance between these two approaches does vary. In developing countries with low literacy rates or a lack of consumer awareness, reliance on labeling may not provide sufficient consumer protection. In these countries there tends to be a greater reliance on product standards. In many economically developed countries or regions, the approach to recipe law, which was prevalent during the mid-twentieth century, has largely been replaced by the use of informative labeling controls.

Applied Nutrition

Limited attempts to protect or improve health by food law have been adopted for some time. The main control has been the requirement for fortification of certain foods so as to restore or enhance the consumption of key micronutrients. Examples include the addition of vitamins and minerals to margarine, milk, flour and bread, and the iodization of salt. These targeted dietary interventions have usually been successful in achieving their limited objectives.

On a larger scale though, many countries are now facing a significant public health problem due to changes in diet and lifestyle. Examples of these are the increasing levels of obesity, diabetes, and of cardiovascular disease. The issue though is how to tackle the causes. Encouraging people to adopt a healthier lifestyle may be possible, but adopting policies which can lead to a healthier diet are also being considered and adopted. Possible options include a return to some vertical controls, but an alternative is the use of more detailed labeling and advertising controls including enhanced nutritional guidance and tighter controls on nutrition and health claims.

Other Objectives

These three different objectives cover most issues which are normally regarded as food law. However, as food can have a great significance within a country's culture and economy, often laws are passed which have an impact on the food supply situation, but which have their origins outside the objectives described above. For example, countries with a large agricultural economy may seek to protect their farmers or rural industries by adopting certain protective measures, whereas some countries use food law to ensure compliance with religious rules. Often general controls applied to protect the society from a wide range of risks will also impact businesses in the food chain – for example, weights and measures, health and safety, customs and taxes, plant and animal health, animal welfare, or environmental controls. These wider controls are not normally considered as 'food law' but food businesses need to comply with all relevant legislation.

Written Food Legislation

This article relates to 'food legislation.' An alternative phrase is 'food law.' However, there can be a confusion as the terminology can vary between countries. The following definitions have been provided by the FAO (2006, p. 39) (Strengthening National Food Control Systems – Guidelines to Assess Capacity Building Needs):

> **Food legislation** (or food law) is the complete body of legal texts (laws, regulations and standards) that establish broad principles for food control in a country, and that governs all aspects of the productions, handling and trade of food as a means to protect consumers against unsafe food and fraudulent practices.
>
> **Food regulations** are subsidiary legal instruments (usually issued by a minister rather than by parliaments) which prescribe mandatory requirements that apply to various aspects of food production, handling, marketing and trade, and provide supplementary details that are left open in the main parliamentary-level legislation.

Food standards are nationally or internationally accepted procedures and guidelines (voluntary or mandatory) that apply to various aspects of food production, handling, marketing and trade to enhance and/or guarantee the safety and quality of food.

Even the above definitions are not fully satisfactory and, in particular, leave the boundaries to some of the terms rather vague. One main difficulty is the use of the term 'standards' in different situations. The International Organization for Standardization adopts and recommends standards. However, in most countries these are only considered advisory unless made mandatory by a legal provision (such as a regulation). Care is therefore needed when discussing national legal structures.

It can also be mentioned that the written legal documents are subject to interpretation. Although those drafting the legislation may have attempted to ensure clarity and precision in the text, those attempting to comply with the provisions may not be certain how to interpret the requirements. When first written, a general concept may sound sensible, but its application may cause difficulties. Words such as 'misleading,' 'legible,' 'misbranded,' or 'hygienic' are often used, but need interpretation. This may happen by additional guidance being issued by the authorities or the adoption of detailed codes of practice (which may, like standards, be either voluntary or mandatory). Alternatively, a complex issue may result in a case being taken to court resulting in a judgment or adjudication which can be applied more generally. Over time these judgments ('case law') can become an important component of the food legislation framework.

The creation of a legal basis for food control is vital if it is to be effective in protecting consumers. It is to be expected and hoped that the vast majority of food suppliers will wish to ensure that the food they supply is safe and meets consumers' requirements. However, there will be others who are prepared, either through negligence or a desire for personal gain, to put consumers at risk or to defraud them. Legislation is, therefore, necessary to provide a deterrent to minimize the numbers who are prepared to take this risk.

The written legal documents need to provide a comprehensive structure for food control. Key elements which are usually found in the main food legislation are:

- *Introductory provisions*: Legislation works best if there are clear definitions and it is common to find key terms defined in the law. Common definitions are for 'food,' 'food business,' 'safe food,' 'food adulteration,' and 'hazard.'
- *Enabling and administrative provisions*: This will identify which public authorities have responsibility under the law and may establish an agency or board to act on behalf of government. The law will also specify the enforcement authority and the powers of the inspectors to enter the premises and to take samples.
- *Offenses and penalties*: Key offenses are usually created which provide general protection from unsafe food or food which is labeled in a misleading manner. The penalties have to be sufficient to deter potential offenders.
- *Specific provisions on food*: Depending on the priorities in a country, the law is likely to contain a number of specific controls. These could relate to import and export conditions or to the requirements relating to the registration of a product or licensing of the premises. More generally, the law is likely to provide the authority for the adoption of secondary legislation in the form of food regulations.

Although the fundamental components of the main food law may not need to be changed very often, it is necessary to ensure that it remains an effective legal document. This requires a regular review of its provisions.

The secondary legislation in the form of food regulations will contain the main details required for effective food control. The more technical requirements contained in the food regulations are likely to be more regularly updated as new information becomes available on potential hazards or as technological advances introduce new substances or processes into the food supply chain.

These food regulations can be categorized into three main types:

Regulations Affecting Specific Food Products

To protect consumers from adulteration, legislation frequently sets out to define the acceptable components of food products and to establish acceptable processing procedures for them. Example of these can be bread, chocolate, coffee, and baby foods. This type of control, referred to above not only as 'recipe law' but also frequently termed as 'vertical' legislation, provides a high level of protection for consumers because manufacturers are forced to manufacture only to recipes which meet the legal requirements. The disadvantage is that the consumer is provided with a limited range of foods and choice is restricted.

Regulations Affecting Food Products in General

An alternative approach to control is to concentrate on more general issues and to establish criteria which can be applied to any type of food. For example, controls on food hygiene or food labeling can be adopted, which require all foods to be manufactured under specified hygienic conditions and to be packed with labels which provide a detailed list of ingredients. To distinguish these controls from the product-specific regulations, these are often termed 'horizontal' controls and allow much greater flexibility for the food manufacturer to be creative in their product development giving consumers a much wider choice of products on the market. However, consumers have to be aware that the composition of the products may not be regulated and hence will need to consider the information provided on the label while making a purchase decision. Additional areas covered by these more general regulations can be food additives (although specific requirements for food additives may also be found in the product-specific regulations), food contaminants (including environmental contaminants and pesticide, and veterinary drug residues), and controls on food-contact materials (whether packaging, food processing equipment or tableware and utensils).

Regulations for Organizational or Coordinating Purposes

The third type of regulation covers a broad range of supporting controls which give more detail as to the manner in which the legal controls operate. Example might include, the procedure for the issuing of licenses or of the taking of samples. There may need to be minimum standards of training for the food inspectors or the analysts working in laboratories. Specific controls may be applied to imported or exported foods to ensure compliance with national legislation or international obligations. These administrative controls may be considered routine, but can be just as necessary for the effective application of the food legislation.

The Application of Food Legislation

The effectiveness of food legislation is only confirmed by inspection and monitoring.

Inspection

A definition of 'food inspection' has been provided by the FAO (2006, p. 66) (Strengthening National Food Control Systems – Guidelines to Assess Capacity Building Needs):

> **Food inspection** is the examination of food or systems for the control of food, raw materials, processing and distribution, including in-process and finished product testing, in order to verify that they conform to requirements. Food inspection can be operated by government agencies, as well as independent organizations that have been officially recognized by national authorities.

Inspection at all stages in the food supply by official enforcement officers is necessary to provide the public with an assurance that those who fail to meet the legal requirements are detected and prevented from continuing in such a manner. It is also helpful to the food businesses who are complying with the law to know that competitors who fail to meet the same standards will not be permitted to continue.

Modern inspection systems use a professional and systematic approach built on a risk-based program of inspections. Examples of key components of the food inspection system are:

- Documented policies and procedures for risk-based inspection.
- Database of food premises categorized by risk.
- Adequate professional food officers with appropriate training, qualifications, and experience.
- Access to resources including facilities, equipment, transport, and communications.
- Procedures for the collection and handling of food samples.
- Procedures for handling food emergencies, outbreaks of foodborne disease and consumer complaints.

Monitoring

Once the enforcement officers have taken a sample, it is essential that it is subject to the appropriate testing. This requires an official laboratory to be available which can provide the officer with a clear and accurate statement of the physical, chemical, or microbiological status of the food sample. The result of the analysis should be capable of being used as evidence in any subsequent court proceedings. As such, the analysis needs to be conducted to a high level of integrity ensuring that the methodology is appropriate and it meets national or international standards. Beside enforcement samples taken in cases of suspected violation, random sampling is essential for providing an overall assurance that the food supply is safe, particularly from chemical hazards.

To help ensure that the laboratories are appropriately staffed and using appropriate techniques, it is common for them to participate in proficiency schemes in which their performance is independently judged in comparison with other official laboratories. The maintenance of high standards of analytical procedures linked to the use of standardized methods aids the accuracy of the results.

Although many routine analyses can be conducted with a fairly limited range of analytical equipment, advances in technology and the need to detect low levels of contaminants (e.g., pesticide residues or aflatoxins) have increased the range and sophistication of the equipment needed for official laboratories.

The Regionalization of Food Legislation

As described in section Key Objectives, governments of individual countries have responsibilities to their citizens to provide adequate protection. However, they also have responsibilities to promote economic development, and the promotion of trade is seen as an effective way to achieve this. Adopting national legislation may be important for consumer protection, but if every country adopts its own set of controls, the result can be to create non-tariff barriers which make it complex and expensive for businesses to trade – whether for imports or exports. One of the main objectives in working together as regional blocks is to try and adopt harmonized controls which enable unnecessary barriers to be removed and for trade to take place smoothly and with only limited interruption when crossing frontiers.

Various different regional groupings now exist around the world and they have different roles and objectives – some go well beyond the desire to seek harmonization but they still incorporate the general objective of harmonization and the abolition of barriers. One such example, the European Union (EU), will now be considered in more detail.

Although originally founded in 1956 as an 'economic' community, the EU has evolved over the years into a more extensive 'political union.' The scope of EU food law has evolved during this transition. Originally food legislation was focussed on removing barriers to trade by the adoption of harmonizing measures. Early food law was adopted for products such as jam, chocolate, sugar, and dried milk. Additional barriers caused by differences in food additive legislation led to the adoption of positive lists of EU food additives (e.g., colors, antioxidants, and emulsifiers) and the creation of the food additive identification 'E-number' system. Food hygiene legislation was adopted to ensure that harmonized meat

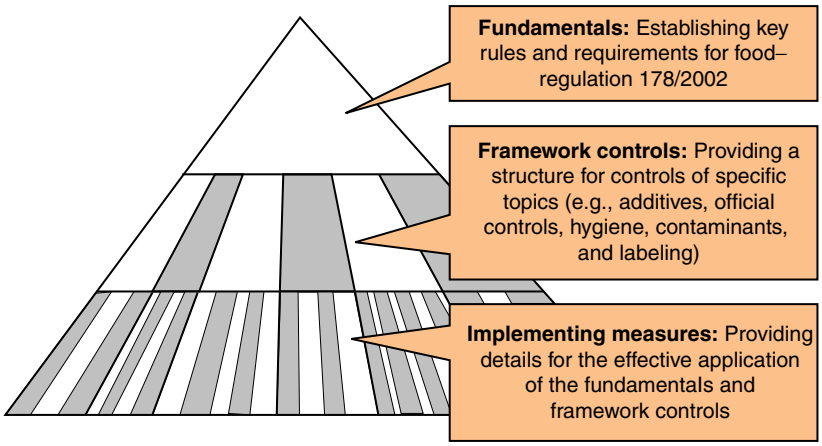

Figure 2 Structure of EU food legislation.

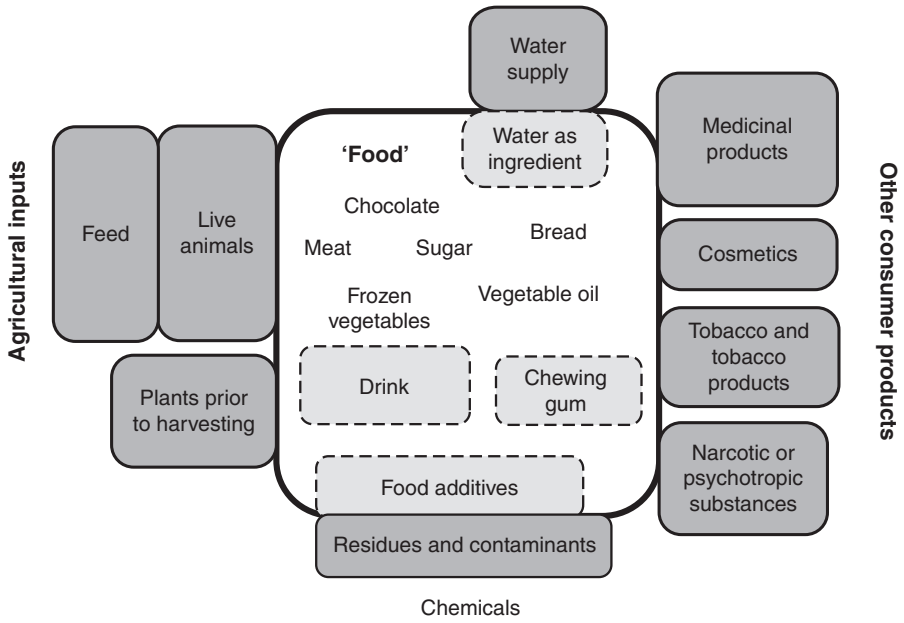

Figure 3 Boundaries related to food legislation.

inspection procedures were employed usually based on veterinary supervision. These were progressively developed to cover a wide range of animal-based products (e.g., poultry, red meat, eggs, milk, and fish).

Attempts were made during the 1970s and 1980s to provide a more systematic approach to this body of legislation. However, it was the food safety crises of the 1990s (in particular, the combination of the bovine spongiform encephalopathy epidemic in cows and the finding of dioxin residues in animal-based products) that led to the creation of a more comprehensive structure for EU food legislation. This is illustrated in Figure 2.

It was mentioned earlier that it is necessary to have detailed definitions included in the legislation. This can be illustrated with a diagram summarizing the definition of 'food' now used in EU food legislation. A detailed provision in Regulation 178/2002 provides the exact definition for EU purposes, but the aim of the definition is to define the boundaries to the concept of 'food' and to ensure that those subject to the controls can determine whether they are included, subject to a different set of controls, or excluded completely.

With the definition of food, the major areas of debate are the exact point at which the primary food producers (e.g., farmers or fishermen) become subject to the controls and the distinction between 'food' and 'medicines'/'drugs.' Other boundary issues involve the supply of water and environmental contaminants. This is presented schematically in Figure 3.

Most EU food legislation is now in the form of EU 'Regulations' which has a specific meaning as defined in the Treaties establishing the EU. It does not, unfortunately, correspond with the FAO definition of 'food regulation' given earlier. EU

Regulations can contain fundamental aspects of the controls or the much more detailed technical requirements contained in implementing measures. An alternative form of EU legal document is the 'Directive' which requires national implementation before it becomes a law in each member state. Although this was the preferred form used in early EU legislation, nearly all controls are now adopted as EU Regulations which define legal requirements in all member states from their date of application. Defining enforcement and penalties are still left to each member state according to their national legal rules.

The EU has now managed to create a body of food legislation which covers all key aspects of food production, manufacture, distribution, and sale. Where there are gaps, national rules still apply. Differences in these national rules can still create barriers to trade, although in general these are often limited to minor technical aspects or differences in interpretation of the EU requirements. The willingness to work together to move from a multitude of national controls to a common set of binding controls was difficult to achieve and took many years. Ultimately, a recognition that in a world where trade is now global and the safety of our food supplies are only defined by the weakest link in the chain led to the EU national governments being willing to move to a set of common rules. Similar moves are happening in other regions of the world although there is a wide variation in the stages reached.

International Standards and Harmonization of Food Safety Legislation

GG Moy, Food Safety Consultants International, Geneva, Switzerland
Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland

Glossary

Compliance A situation in which products and/or practice meet regulatory requirements (to be differentiated from conformity, which means that activities are carried out according to the established procedures).

Food legislation Laws and regulations intended to protect and promote the identity, integrity and safety of the food supply and to facilitate trade.

Harmonization of food safety legislation A process by which appropriate national food laws and regulations are established, amended or administered with the view of ensuring the safety of food and facilitating domestic and international trade.

Risk analysis A process of decision-making (usually by government) for managing food safety, consisting of three components: risk assessment, risk management and risk communication.

Risk assessment A scientifically-based process for evaluating risks associated with foodborne hazards, consisting of the following steps: (i) hazard identification, (ii) hazard characterization, (iii) exposure assessment, and (iv) risk characterization.

Risk communication The interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Risk management The process, distinct from risk assessment, of weighing policy alternatives, in consultation with all interested parties, considering risk assessment and other factors relevant for the health protection of consumers and for the promotion of fair trade practices, and, if needed, applying appropriate prevention and control options.

Introduction

International trade in food and feed, international travel, and development of mass communication media have all contributed to the globalization of food safety risks to virtually every country in the world. This globalization of risks includes not only real risks, such as those posed by microbial or chemical hazards, but also perceived risks, such as those generated by media coverage rather than objective assessments of the risk. Globalization presents a unique challenge to governments and the food industry and calls for a more harmonized approach to the management of food safety risks at the international level. As food safety legislation is the foundation for food safety management, harmonization of national laws and implementing regulations will serve to protect consumers everywhere and facilitate international trade in food.

Food safety legislation can cover a broad range of subjects, including food additives, pesticides, veterinary drugs, food contact materials, contaminants, nutrition, labeling, claims, novel technologies, requirements for safe operation, and procedures for the administration of food control. This article focuses on the contributions of international organizations, in particular, the Codex Alimentarius Commission (Codex) and its two parent bodies, the World Health Organization (WHO) and the Food and Agriculture Organization (FAO), to the harmonization of food safety legislation.

At the outset it should also be pointed out that harmonization of food legislation is not necessarily a process of developing one law for all nations. Rather, it is a process by which appropriate national law is established and administered with the view of ensuring safety standards taking into account the national situation and at the same time, the facilitation of domestic and international trade.

Purpose of Food Safety Legislation

Food safety legislation is an essential public health function of governments. The term legislation encompasses basic food law and implementing regulations as well as any adjudication by the courts. In most countries, food law lays out the basic mandate for compliance and administrative policy and the operational programs to be implemented by the competent national food control authority. However, food safety regulations provide specific and detailed information needed to comply with the provision of the law, such as various standards. They also provide the basis for specific administrative,

procedural, and technical requirements to ensure food safety. The main goals of food safety legislation are to:

- protect and promote public health;
- protect consumers from products that are spoiled, fraudulent, or otherwise unfit for consumption; and
- provide consumers with relevant and accurate information so that they can make informed choices with regard to safety and nutrition.

Although not often duly acknowledged, food safety legislation is also of great importance to the food industry as it serves to:

- promote fair trade by ensuring a consistent standard among competing businesses;
- increase the confidence of consumers in the food supply;
- provide guidance and norms on matters related to food safety;
- provide data for validating food safety assurance systems of the industry; and
- ensure that all stakeholders of the food chain, i.e., both suppliers and customers, fulfill their roles.

Importance of Global Harmonization

Since the mid-twentieth century, the world trade in food had begun to increase dramatically. By 2010, global food trade was estimated to exceed USD$1 trillion and to include not only primary food commodities but also an ever growing number of food ingredients and processed food products. Globalization has also had consequences on food safety. Many food safety incidents have shown how domestic problems can have global implications. For example, the melamine problem in milk (China, 2008) and the bovine spongiform encephalopathy (BSE) outbreak (UK, 1996) had international repercussions for health and trade. Furthermore, the complexity of the international food trade network has resulted in a situation where the origin of a food (and a food safety problem) cannot always be easily traced, such as the cases of *Salmonella*-contaminated Serrano and Jalapeño peppers imported from Mexico (USA, 2008) and fenugreek seeds from Egypt contaminated with enterohemorrhagic *Escherichia coli* O104:H4 (France and Germany, 2011). Nor is it possible to easily trace forward a problematic product that has entered international commercial channels, as was the case with sauces made from chili imported from India that was adulterated with Sudan Red (UK, 2003). Problems with contaminated food moving in international commerce are occurring with disturbing regularity. Additionally, the rapid dissemination of information through the 24/7 news cycle and social media is raising consumer concerns for food safety and placing greater pressure on both industry and national food safety authorities to address food safety problems promptly.

For many countries, food export is a major source of foreign exchange earnings and an important factor for economic development. Underdevelopment is a major cause of poverty, which itself is the source of many of society's ills, including foodborne diseases and marginal practices affecting food safety. The latter exacerbate the food safety situation and jeopardize food exports. Whereas food standards should be health based and adequate to protect the health of consumers, food standards that cannot be justified on sound scientific grounds will create nontariff barriers to trade, often damaging the economies of developing countries. For food businesses, the harmonization of food legislative is also of primary importance as producing food according to the different requirements of countries further complicates food production operations that are already inherently complex. This not only decreases efficiency in production but also increases operational risks and costs.

There is also another fundamental reason for which global harmonization of food legislation is important. In their World Declaration on Nutrition, the ministers and the plenipotentiaries representing 159 states of the then European Economic Community recognized that 'access to nutritionally adequate and safe food is the right of each individual.' This universally accepted principle maintains that all individuals have a basic human right to the same standard of food safety and the same degree of health protection. Global harmonization of food safety legislation is therefore a major step in recognizing this right.

Historical Background

The development of food legislation started in the early period of human civilization, as many cultures and religions made provisions with regard to foods to ensure they were authentic, hygienic, and fit for human consumption. For example, the Persians standardized certain food commodities within their empire as a result of concerns for food adulteration and fraud. However, in those times, the basis for food safety was not really understood and many measures were not effective. Beginning in the Middle Ages in Europe, food producers in some countries formed trade guilds to promote the quality and safety of their products. However, it was not until the industrial revolution that countries began to establish science-based food safety legislation.

In the mid-1800s, Louis Pasteur unequivocally demonstrated the validity of germ theory and extended this knowledge to the field of food science and technology. This scientific approach led to safer, better quality food products and arguably, to our modern food supply system. Also during this time, growing urbanization increased the distance between producers and consumers, which created new opportunities for fraud and contamination. For example, the gross hygienic practices in the large stockyards in Chicago in the early 1900s outraged the population and led to the first US food safety legislation in 1906. By the mid-twentieth century, international trade, facilitated by advances in transport and food-processing technologies, started its enormous growth and underpinned not only the need for national food safety legislation but also its harmonization.

At the international level, some of the earliest international standards were those for milk and dairy products, which were elaborated by the International Dairy Federation in 1903. In the late 1940s, there were several attempts to establish regional food codes. In 1949, Argentina proposed a regional Latin American Food Code, the 'Codigo Latino-Americano de Alimentos.' In the

mid-1950s, Austria also pursued the creation of a regional food code, the 'Codex Alimentarius Europeaus.' The establishment of the FAO in 1945 and the WHO in 1948 was the foundation for food safety at the international level. Whereas FAO was given the mandate to establish international standards for quality and composition of foods and WHO was given the mandate to establish health and safety standards for food. These compatible mandates were the basis for the establishment of the Joint FAO/WHO Food Standards Programme and its Codex Alimentarius Commission, which is described below.

Codex Alimentarius Commission

The premier international body overseeing harmonization of food safety legislation is the Codex Alimentarius Commission (Codex) which was established as an intergovernmental body by FAO and WHO in 1963 under the Joint FAO/WHO Food Standards Programme. Codex develops harmonized international food standards, guidelines, and other recommendations to protect the health of the consumers and ensure fair practices in the food trade. These are compiled in a set of documents known as the 'Codex Alimentarius' (Latin for 'food code'). The Commission also promotes coordination of all food standards work undertaken by international governmental and nongovernmental organizations. Member countries of Codex now include 99% of the world's population. Many developing countries actively participate in the work of Codex – in many cases assisted by the Codex Trust Fund, which strives to finance and train participants from such countries. Being an active member of Codex helps these countries to compete in sophisticated world markets and to improve food safety in their own countries.

The Secretariat of Codex is housed at the FAO Headquarters in Rome and operates through a number of commodity committees and general subject committees. The procedures for adoption include an eight-step process of discussion and consultation with member countries, concluding with the formal adoption by full commission, which meets every year, alternating between Rome and WHO headquarters in Geneva. Most of the early work of Codex related to recommendations for international standards for food commodities, which were vital for facilitating the growing international trade in food. For example, such standards allow exporters know what importers demand, and importers are protected from substandard shipments. Some of these standards included sections that dealt with food safety issues, such as permitted food additives and maximum residue levels for pesticides. However, the real food safety harmonization work of Codex is now carried out by its horizontal committees, which address issues that apply across all foods. These include the following Codex Committees:

- Food Hygiene;
- Food Additives;
- Contaminants in Food;
- Pesticide Residues;
- Residues of Veterinary Drugs in Food;
- Nutrition and Special Dietary Uses;
- Labeling; and
- Methods of Analysis and Sampling.

In addition, Codex has convened several task forces on topics of interest to food safety, including animal feeding, foods derived from biotechnology, and antimicrobial resistance. A summary of the achievements of Codex in international harmonization is given in **Box 1**.

Until the mid-1990s, the 'Codex Alimentarius' was considered only as recommendations to its member states who were free to accept, modify, or reject them. Although the work of Codex was often used as a reference for national legislation, adoption of Codex recommendations was often inadequate. For example, a study comparing the regulatory requirements of the European Union (EU) with those adopted by the Codex Alimentarius Commission found many discrepancies. Furthermore, the study estimated EU standards resulted in a considerable loss of revenue from exports of cereal, edible nuts, and preserved fruit. For a number of African countries, this reduced their exports by USD$670 million per year. Thus, food safety standards by importing countries that are too stringent can create unjustified trade restrictions and contribute to underdevelopment and poverty in developing countries.

Box 1 Standards, guidelines, and other recommendations of the Codex Alimentarius

Number	*Topics*
186	Commodity standards
46	Commodity-related texts
9	Food labeling provisions
5	Food hygiene provisions
3	Food safety risks assessment
15	Methods of sampling and analysis
8	Inspection and certification procedures
6	Animal food production provisions
153	Maximum levels for contaminants including detection and prevention methods
1112	Food additives provisions covering 292 food additives
7	Food additives-related texts
2930	Maximum limits for pesticide residues covering 218 pesticides
441	Maximum limits for veterinary drugs covering 49 veterinary drugs
3	Regional guidelines

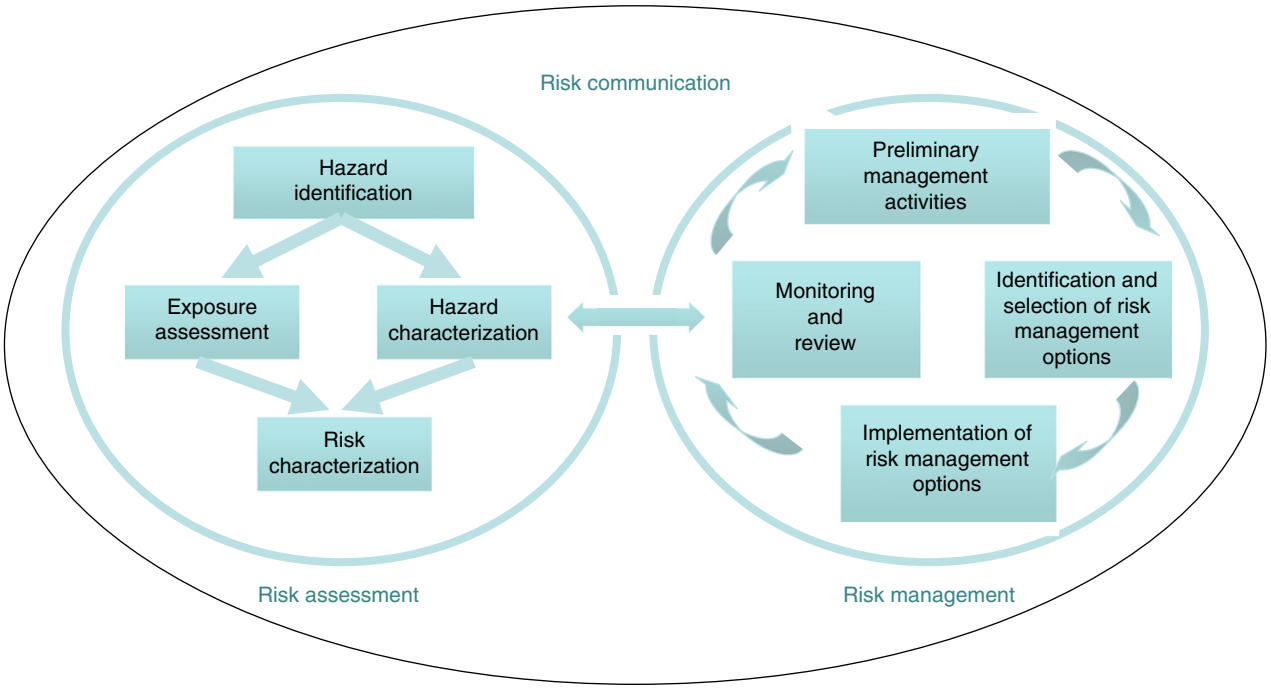

Figure 1 Generic framework for risk analysis.

Consequently, global harmonization of food safety regulations is of paramount importance in the twenty-first century.

Codex and World Trade Organization (WTO) Agreement

The Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement) of the WTO recognizes that governments have the right to take sanitary measures, but it specifies that such measures should be based on sound science to the extent necessary to protect human health, and that such measures should not discriminate unjustifiably between member countries where identical or similar conditions prevail. The SPS Agreement recognizes the food safety standards, guidelines, and other recommendations of Codex as representing the international consensus on health and safety matters. As such, member countries that comply with Codex are considered to be in compliance with the SPS Agreement. It is also expected that WTO member countries accept the sanitary measures of others as being equivalent if the exporting country demonstrates to the importing country that its measures meet the importing countries' appropriate level of health protection. New terms, such as 'food safety objectives' and 'performance objectives,' have been coined to determine appropriate levels of health protection in relation to food safety and facilitate the principle of 'equivalence' in the context of the SPS Agreement. Although these concepts are still being debated internationally, the SPS Agreement has nevertheless played a major role in encouraging countries to bring their legislation into line with international food standards, guidelines, and recommendations. Note that if a country adopts a higher level of protection than that afforded by Codex, the country must do so based on an appropriate assessment of the risk.

The WTO's Agreement on Technical Barriers to Trade (TBT Agreement) is also important to food trade and particularly to food labeling. It provides member countries with the right to consider other legitimate factors in their decision-making process. Examples of such factors are considerations regarding the environment, animal welfare, and consumer preferences.

After the SPS Agreement came into force in 1995, FAO and WHO convened a series of three consultations on risk assessment, risk management, and risk communication that are the components of risk analysis. Reports of these consultations were subsequently considered by Codex, which developed a set of principles and recommendations related to the use of risk analysis in standard setting. Although these principles and recommendations were directed at member countries, Codex itself began a process to integrate them into its own procedures. One of the principles was the functional separation between risk assessment and risk management, yet with adequate risk communication between them. However, this already existed in Codex because its risk assessment advice is provided by FAO/WHO expert meetings, including the Joint FAO/WHO Expert Committee on Food Additives, the Joint FAO/WHO Meetings on Pesticide Residues, and the Joint FAO/WHO Meetings on Microbiological Risk Assessment. Other recommendations relate to the process of food safety management from scientific evaluations to the risk management decisions, including consideration of other legitimate factors as well as communication with all stakeholders. An overview of this process is shown in Figure 1.

These principles and recommendations are also reflected at national and regional levels. For example, the European Food Safety Authority was created with the responsibility of conducting risk assessments for risk management, which remained with the European Commission. Although these

principles have been adopted nationally in many countries, notably in North America and Europe, there are differences in their implementation, in particular, with regard to risk management decisions and how uncertainties in risk assessment and other legitimate factors should weigh in the decision-making process.

In Europe, past experience with BSE and consumer reaction to the BSE crisis have influenced the process of risk analysis so that the decision-making process is:

1. more conservative in its approach, including the application of the 'precautionary principle' in times of uncertainty and
2. more attentive to consumer perceptions and preferences regarding food safety risk and ethical and environmental issues.

In North America, the general public is less averse to modern methods of food production and processing; however, large-scale foodborne disease outbreaks, in particular, outbreaks of *E. coli* O157:H7 affecting children, have led to the strengthening of food safety legislation.

WTO Dispute Settlement

In addition to the international agreements on trade, the WTO also provides judgment in disputes related to the SPS Agreement and may require members to modify or withdraw their noncompliant sanitary measures or face punitive measures. The WTO can authorize countries affected by the violation of the SPS Agreement to take retaliatory measures. The unsuccessful intervention of the WTO in resolving the US–EU hormone-treated beef dispute is an example of the difficulties in harmonizing food legislation even with the SPS Agreement in place.

International Health Regulations (IHR)

Concomitant with the increasing industrialization of the world in the early 1800s, international travel and migration also expanded, and along with this, a greater risk of spreading infectious diseases. In 1830 and again in 1847, major cholera epidemics struck Europe caused by imported cases and catalyzed international cooperation in public health that led to the first International Sanitary Conference in Paris in 1851. Exactly 100 years later and 3 years after the establishment of WHO in 1948, WHO member states adopted the International Sanitary Regulations, which were later renamed the IHR. The IHR is an international legal instrument, binding 194 countries to fulfill the obligations in regard to disease outbreaks of international public health concern. The aim of IHR is to prevent and respond to public health risks that have the potential to cross borders and threaten people worldwide. The latest revision of IHR came into force on 15 June 2007 and greatly expanded the scope and coverage of the IHR, which explicitly include food. The IHR requires countries to report certain disease outbreaks and public health events of international concern to the WHO. Under this requirement, WHO member states are requested to report a contaminated food product that may be, or is suspected to be, of international public health concern. To support exchange of information on contaminated food products entering international trade, in 2004, WHO in collaboration with FAO established the International Food Safety Authorities Network, which includes a food safety emergency component coordinated with IHR.

International Organizations

In the context of harmonizing food safety legislation, a number of international organizations merit mentioning. Some of these are covered in more detail in separate articles.

WHO

WHO is the directing and coordinating authority for health within the United Nations system. It is responsible for providing leadership on global health matters, shaping the health research agenda, setting norms and standards, articulating evidence-based policy options, providing technical support to countries, and monitoring and assessing health trends. With headquarters in Geneva, WHO is one of the more decentralized of the United Nations agencies with six regional offices located around the world. These offices are staffed with regional food safety advisors who work directly with the countries to strengthen their food safety programs. Given its mandate in food safety, some of its earliest publications of WHO in the 1950s were on the food safety topics, such as milk pasteurization, meat hygiene, safety of food additives, and safe use of pesticides. The Department of Food Safety and Zoonoses (FOS) in WHO Headquarters provides leadership in WHO's global efforts to lower the burden of diseases from food and animals. In carrying out its activities, FOS focuses on

- providing evidence-based scientific options for policy development to protect consumer's health and manage food safety;
- developing mitigation strategies to prevent, control, and contain risks;
- setting international standards and promoting their implementation;
- coordinating international efforts in food-related outbreak surveillance, detection, and response;
- ensuring clear risk communication in support of foodborne and zoonotic disease prevention and control; and
- providing technical support to assist member states in building sustainable capacity.

WHO works closely with the FAO as well as the World Organisation for Animal Health (OIE) and other international organizations to address food safety issues along the entire food supply chain from production to consumption.

FAO

Based in Rome, FAO's primary mandate is to raise levels of nutrition, improve agricultural productivity, better the lives of rural populations, and contribute to the growth of the world economy. The food safety activities in FAO are mainly located in the Food Safety and Quality Programme under the Nutrition and Consumer Protection Division. The activities of the program include

- providing independent scientific advice on food safety and nutrition which serves as the basis for international food standards;
- developing institutional and individual capacities for food control and food safety management in countries, including the management of food safety emergencies;
- supporting processes for the development of food safety policy frameworks;
- facilitating global access to information; and
- encouraging and supporting the development of food safety and quality networks.

This division also houses the secretariat of the Joint FAO/WHO Food Standards Programme and its Codex Alimentarius Commission, which is the most important body for international food safety harmonization.

WTO

The successful conclusion of the Uruguay Round of Multilateral Negotiations led to the establishment of the WTO in 1995. Based in Geneva, the mandate of the WTO is to undertake negotiations to liberalize international trade. The organization deals with regulation of trade between participating countries by providing a predictable framework for negotiating and formalizing trade agreements. It also offers a dispute resolution process aimed at enforcing participants' adherence to WTO agreements, which are signed by representatives of member governments and ratified by their parliaments. Most of the issues that the WTO focuses on derive from previous trade negotiations, especially from the Uruguay Round. In regard to food safety, two agreements had major implications for the harmonization of food legislation. These were the SPS Agreement and the TBT Agreement. In regard to the SPS Agreement, sanitary measures relating to animal and human health are referred to the OIE and Codex Alimentarius Commission, respectively, whereas phytosanitary measures relating to plant health is referred to the International Plant Protection Convention.

OIE

The OIE is an intergovernmental organization that was established in 1924 as the result of an international incident involving the transmission of rinderpest. The organization is based in Paris and still uses its French acronym OIE (from Office International des Epizooties). The primary mandate of OIE is to improve animal health worldwide. OIE currently has 178 members and maintains liaison with 35 international and regional organizations. The OIE is referred to in the WTO SPS Agreement in regard to animal health issues. Among its activities is the timely dissemination of information regarding animal disease outbreaks, which is facilitated by its World Animal Health Information System (WAHIS). Under WAHIS, rapid notification and follow-up reports are provided to countries in response to exceptional and/or international animal disease events. In this regard, OIE has worked closely with both WHO and FAO in responding to the global outbreak of avian influenza. OIE was also very involved in the control and eradication of BSE.

International Organization for Standardization (ISO)

In operation since 1947, the role of ISO is to facilitate the international coordination and harmonization of industrial standards to promote international exchange of goods and services. ISO is a nongovernmental organization, and as such, its standards are voluntary and not enforceable as regulations. Nevertheless, some of its standards, in particular those related to health, safety, and environment, have been adopted in some countries as part of their regulatory framework or are referred to in their legislation. ISO standards are developed by experts in the industry or business sector. They are therefore referred to as private standards. Standards with regard to food are developed under the Technical Committee on Agriculture (ISO/TEC 34). Under this committee, over 500 international standards have been adopted and over 100 more are underdevelopment. With regard to food safety, the ISO 22000 standard entitled 'Food safety management systems – requirements for any organization in the food chain' has received attention in regulating the customer–supplier relationship.

In addition to these international organizations, other efforts to promote harmonization of food safety legislation have been undertaken by nongovernmental organizations. Some of these are described below.

Global Harmonization Initiative (GHI)

The GHI is a nongovernmental initiative with the goal to specifically promote harmonization of food safety legislation. In the context of this initiative, since 2004 food scientists from all over the world have been working to achieve a global consensus among scientists on food safety issues and to provide tools for facilitating the global harmonization of food legislation.

Safe Food International (SFI)

SFI is a project designed by and for consumer organizations that want to improve food safety on a global scale. SFI aims to unify and focus the efforts of consumer organizations worldwide that are working to ensure a safer food supply by assuring that their national food safety legislation addresses common food safety problems. At a conference in 2005 cosponsored by the WHO and FAO, consumer organizations shared their food safety expertise and developed a common vision of how to strengthen national food safety systems, including legislation. Based on consensus and endorsed by the WHO and FAO, SFI published its 'Guidelines for Consumer Organizations to Promote National Food Safety Systems,' which have become the basis for training and advocacy by consumer organizations around the world. Consumers International and the International Association of Consumer Food Organizations – both international umbrella organizations composed of consumer organizations – also provided important assistance in the development of the guidelines.

There are also a number of other international nongovernmental organizations that directly or indirectly promote harmonization of food safety legislation, including the

International Union of Food Science and Technology, Confederation of European Food Industries, International Life Sciences Institute, and International Commission on Microbiological Specifications for Foods. These are covered in separate articles related to those organizations.

Future Challenges

Despite its importance, global harmonization of food safety legislation will remain a major challenge for the twenty-first century. The international community will have to reach an agreement on a multitude of food safety issues that provides adequate health protection, but at the same time

- meets the expectations of consumers;
- allows economic and trade growth;
- advances food science and technology; and
- ensures fair competition between large and small industries as well as between industrialized and developing countries.

PUBLIC HEALTH MEASURES

Food Inspections and Enforcement Systems

CS DeWaal, D Plunkett, and C Roberts, Center for Science in the Public Interest, Washington, DC, USA

Glossary

Adulteration A legal standard applied to distinguish food that is inferior, contaminated, produced under insanitary conditions, or different from an identity standard; or food that contains harmful, less valuable, or prohibited substances.

Civil penalties Civil fines can be applied administratively or by a court for lesser violations of law, providing a more flexible response to corporate misconduct that can be tailored to the violation.

Codex Alimentarius A collection of internationally recognized standards, codes of practice, guidelines, and other recommendations relating to foods, food production, and food safety.

Criminal penalties Criminal fines or incarceration are applied to individuals or firms following conviction on charges of criminal behavior in a court of law.

Detention An order, typically issued by a government authority, to temporarily hold a shipment of food so that it cannot enter commerce pending a more thorough examination.

Inspection The examination of food or systems of food control in order to ensure that food meets the requirements set by government authorities.

Recall Recalls are actions taken by a firm to remove a product from the market. Recalls may be conducted on a firm's own initiative, by request from a food safety agency, or, in the case of a mandatory recall, by order under a food safety agency statutory authority.

Traceability The ability to follow the movement of a food or ingredient through multiple stage(s) of production, processing, and distribution.

US Department of Agriculture (USDA) The agency that regulates production and importation of all raw beef, pork, lamb, goat, horsemeat, chicken, turkey, duck, and goose as well as processed meat and poultry products and liquid, frozen, and dried egg products in the United States.

US Food and Drug Administration (FDA) The US agency that regulates domestic and imported food products (except for most meat, poultry, and egg products), including processed foods, dairy, shell eggs, seafood, and products which contain minimal amount of meat.

Introduction

Inspection is used to verify that food, and the systems used to produce it, meet the requirements established to protect consumers from foodborne hazards and control deceptive marketing practices. Since ancient times, inspection has been an essential component of regulatory control programs to ensure the safety of food products.

Inspection services give government regulators, customers, and consumers consistent information regarding conditions throughout the food chain. Serving as in-house experts, inspectors have essential information about the food production system that can help in responding to food safety emergencies.

Food inspection services can cover many aspects of the food supply. Many inspection functions are focused on food processing facilities (including slaughter facilities) and at import facilities. Restaurants, farms, storage, and packing facilities can also be subject to inspection. Street vendors are subject to oversight in many places.

A variety of components contribute to the effectiveness of inspections. The number of inspectors and facilities will impact the frequency of inspection. Many programs focus most of their resources on risky foods and higher risk sectors of the food supply, which can leave other sectors without oversight. Inspector training and ethics are also critically important to ensure effective inspections.

Inspection Models, Past and Present

One of the purposes of food inspection is to deter adulteration of food. Where inspection has been mandated by law, there are several models:

- Carcass-by-carcass inspection for slaughter plants has been in place for more than 100 years in the meat industry. Some countries require government inspectors to be present in all slaughter facilities during their operation to inspect each carcass for signs of illness, disease, or filth.

 doi:10.1016/B978-0-12-378612-8.00318-8

- The US and other countries require daily inspection for many high-risk processing facilities such as processed meat, poultry, and egg products.
- Many governments worldwide use random or periodic inspection to check for unsanitary conditions that could lead to adulteration as well as to verify a food facility's food safety system.

When food-related disease outbreaks or other food crises occur, government agencies can be subject to significant criticism. Some governments may practice a reactive approach to inspection, when, for example, they send inspectors to inspect facilities in response to an outbreak or contamination event linked to foods from a similar type of facility. Several governments are working to identify and define the components of a risk-based inspection system for periodic inspections. Under a risk-based inspection system, food facilities are inspected regularly on a schedule that reflects the likely risk to consumers from the type of food produced, not just in response to outbreaks. Consultation with all stakeholders on the elements of the inspection system can help to inform those both inside and outside of government.

Modern Inspection Systems

According to the Codex Alimentarius, inspection is the examination of food or systems of food control in order to ensure that food meets the requirements set by government authorities. Inspection can be applied at many points along the food chain, encompassing raw materials, processing, and distribution. It can also include both in-process and finished product testing.

The World Health Organization (WHO) and the Food and Agriculture Organization (FAO) of the United Nations, in advising governments that are developing or modernizing food safety systems, have defined the responsibilities of inspection systems as follows:

- Inspecting premises and processes for compliance with hygienic and other requirements of standards and regulations.
- Evaluating Hazard Analysis and Critical Control Point (HACCP) plans, their development and their implementation.
- Sampling food during harvest, processing, storage, transport, and sale to establish compliance, to contribute data for risk assessments, and to identify offenders.
- Recognizing different forms of food decomposition, or food that is adulterated, misbranded, or otherwise unfit for consumption.
- Providing evidence and other assistance in law enforcement activities.
- Conducting inspection, sampling, and certification of food products for import/export purposes.
- Examining how rework, noncompliant raw material, products, incidents are managed.

According to FAO/WHO, the effectiveness of the inspection control system is highly dependent on the inspection force, including workforce qualifications, training, and honesty. FAO/WHO recommends that inspection personnel be trained in food science and technology sufficient to allow them to analyze a HACCP program and identify safety or quality problems. Additionally, inspectors must have a wide variety of skills in order to inspect premises, collect samples, conduct an overall evaluation, understand and apply food legislation, collect evidence, and handle HACCP audits.

The Frequency of Inspections

Inspections can be daily (as some countries require for meat and poultry) or periodic. In either case, to maximize consumer confidence, Codex guidance recommends that inspection or other appropriate controls should extend to all stages of production, manufacture, importation, processing, storage, transportation, distribution, and trade.

For periodic inspections, managers should apply principles of risk to ensure an adequate frequency of inspection is maintained, i.e., foods and facilities should be evaluated to ensure high-risk foods are inspected more frequently than those presenting a low risk.

Codex outlines a number of components to consider when assessing the risk of imported foods, many of which apply equally well to domestic products:

- The scientific determination of the food safety risk, based on foodborne illness outbreaks and epidemiologic evidence, risk assessments, and contaminant or residue information, where available.
- The adequacy of processing controls in a country, as evidenced by the laws, infrastructure, and enforcement capabilities.
- The compliance history of the segment of the food industry.
- The compliance history of specific suppliers.
- Reports from other entities such as a foreign government or other local or national agencies, where available.

Regular review of the level of assigned risk helps ensure that the nature and frequency of inspection is appropriately matched to the specific products. The review should be documented, with changes over time recorded.

Other Elements of Legislation that Support Inspection

A number of elements of a food control system can make the inspection program more effective as well as more efficient. For example, an inventory of food facilities operating in or supplying food to a particular country or region facilitates inspection. Here are some provisions in use in different countries:

- Facility registration to provide food control authorities with an inventory.
- Rapid alert systems to ensure effective dissemination of findings of adulteration or misbranding, nationally or regionally.
- National systems to approve HACCP plans and controls, equipment design and use, and standardized training of inspectors.
- Export certification to provide assurance that the specific facility or food meets the standards of the importing country, which can facilitate the trade of foods between countries.

- Laboratory systems that provide the ability to sample and test foods and facilities for specific contaminants.
- Active foodborne outbreak surveillance systems to inform regulators about the foods most likely to cause illness.
- Utilization of state, provincial, or potentially private inspectors to augment the national management scheme.

Enforcement

The role of enforcement is to provide deterrence and to promote the use of best practices. Government sanctions are the primary means of enforcing food safety standards. However, private lawsuits can also serve to promote compliance. Enforcement is important to deter noncompliance in countries where market forces alone do not provide sufficient incentive for businesses to produce safer food.

Important government enforcement tools include:

- Detention: An order, typically issued by a government authority, to temporarily hold a shipment of food so that it cannot enter commerce pending a more thorough examination.
- Seizure: The government takes unsafe food, which may occur without compensating the owners, to prevent it from reaching consumers. Seizures may require a court order.
- Injunction: An agency may seek a court ordered injunction to stop a food establishment from producing or distributing food.
- Civil penalties: A government agency may impose civil fines administratively or go through the courts. Civil penalties provide a flexible response targeted at restoring compliance with food safety requirements.
- Criminal penalties: The government may prosecute individuals or firms, seeking court ordered fines and/or prison sentences. Statutes normally specify the criminal penalties for specific violations.

Other authorities that are useful in enforcing food laws include:

- Business records access: Reviewing process-related business records provides important information to regulators. For example, access to records documenting preventive controls, monitoring and verification during inspections, or tracking information to facilitate recalls in an emergency assists government authorities.
- Mandatory recall: Removing food from the market when a firm violates the law is essential to protect consumers. The threat of a costly recall order can have a strong deterrent effect.
- Tracking food products: Mandating traceability can minimize the impact of foodborne outbreaks by allowing for more rapid identification of food linked to an outbreak. It can also provide evidence of where the problem occurred for purposes of taking corrective action.
- Employee protections: Food handlers and plant employees can provide valuable information to government agencies regarding unsanitary conditions. They may only come forward if they have protection from the threat of dismissal for helping in an investigation.

Government Enforcement

Government actions often begin after an inspection reveals problems in a food establishment, or may occur in response to an outbreak of illness linked to a food. Government agencies may utilize a multistep approach to ensure compliance. For example, they may begin by issuing notices of deficiencies and conducting reinspections to check on a business's corrective actions. If problems are not corrected or the noncompliance is especially egregious, the agency may issue a warning letter. If the product has been shipped to distributors, a business may be asked to voluntarily withdraw or recall the adulterated or misbranded product. Agencies also publicize their findings through a public health warning and through formal administrative procedures.

Some agencies may utilize more direct approaches such as detaining suspect food or levying civil monetary penalties. If the food is subject to continuous inspection or requires approval by government inspectors before being marketed, the agency may withdraw inspectors, which effectively shuts down the business until it demonstrates that it has come into compliance.

Governments may also take firms or individuals to court to seize unsafe food or issue an injunction that stops the firm from manufacturing or distributing their products. The government may seek criminal sanctions if appropriate. Prosecution may target the person who was in a position of responsibility, regardless of whether that person intended to commit a crime. Punishments can include a fine, prison, or both.

Governments can enlist food establishments to enforce standards. For example, the Food Safety Act of 1990 in the United Kingdom provides a due diligence defense to encourage food establishments to take responsibility for their products. A person who can prove he took all reasonable precautions and exercised due diligence to avoid the commission of the offense can escape conviction. One result of having the due diligence defense available has been the emergence of private food safety standard setting and certification bodies.

Private Action

Private enforcement occurs in some countries when a person has been injured by an adulterated or misbranded food product. Lawsuits involving food safety claims can arise from negligence, product liability, or breach of warranty, depending on the facts of the case. In the case of food, product liability claims may follow 'strict liability' doctrine in which there is no need to prove the defendant's conduct contributed to the injury. Although government action focuses on compliance, private lawsuits seek to compensate victims. Even so, the threat of lawsuits can improve compliance.

Conclusion

Inspection is a core function of a national food safety system. It gives regulators, the regulated industry, and consumers information regarding conditions in food facilities and

throughout the food chain that can affect food safety. Advancements in food safety practices over time have changed the scope and purpose of inspections and have put more emphasis on prevention rather than enforcement.

PUBLIC HEALTH MEASURES

Alerts and Early Warning Systems

HJP Marvin and GA Kleter, Wageningen University and Research Center, Wageningen, The Netherlands

Glossary

Emerging risk 'A risk resulting from a newly identified hazard to which a significant exposure may occur or from an unexpected new or increased significant exposure and/or susceptibility to a known hazard' (as defined by European Food Safety Authority's Scientific Committee).

Holistic Focusing on whole systems rather than specific parts of it. In this article, 'holistic' refers to systems and approaches that take account of developments outside the food manufacture chain so as to be able to detect changes that eventually will impact on this chain.

Indicator A qualitatively or quantitatively measurable and sensitive parameter that is indicative of a certain condition of interest. In this article, for example, holistic systems utilize indicators within influential sectors surrounding the food manufacture chain in order to detect developments within these sectors that may eventually impact on the chain itself.

Influential sector A subdivision of society (sector) that exerts influence on other sectors, the latter in this case being the food manufacture chain.

Signal A detected change in the nature or magnitude of the indicator that is sufficiently large to signify changes in the conditions with which the indicator is linked.

Food Safety and Rapid Alert Systems

The repeated occurrence of food safety issues in the last decade has evoked a public concern about the safety of our food production systems and has resulted in a decline in the consumer confidence in the food safety regulation and management inside and outside Europe. In Europe, for instance, the European Commission responded by issuing a new food safety regulation (Regulation (EC) No. 178/2002/EC) often referred to as 'General Food Law.' This regulation clearly describes the food safety framework in European Union (EU) including the responsibility of the different stakeholders in the food production chain. With this law the independent European agency for risk assessment for all categories of food hazards (European Food Safety Authority (EFSA)) was established. In the USA, for instance, the Food and Drug Administration and the Human Health Services launched a joint initiative, the Food Protection Plan, in 2007. With the plan, these federal authorities responded to the increasing globalization of food trade and changing consumption patterns, in order to further safeguard a healthy food supply. This plan extends on the existing food safety and food defense initiatives. It addresses both intentional and unintentional threats, and imported and domestic foods, whereas promoting further cooperation between national (state and interstate) authorities as well as public–private cooperation. It employs advanced information technology tools and aims at addressing risks in a more targeted way. The plan consists of three major pillars, of which one important pillar is prevention, such as through identifying vulnerabilities, introducing good manufacturing practices, and filing prior notices of export to the USA for foods produced abroad. The other two pillars are: (1) intervention, such as through rapid detection methods for signals of contamination and through the application of information technologies; and (2) response, such as through cooperation between authorities. In Japan, the Food Safety Commission, an independent body advising the government on food safety issues, such as the safety of genetically modified foods, pesticides, feed and food additives, contaminants, and antimicrobial resistance in food pathogens, was established in 2003 as laid down in the Japanese Food Safety Basic Law.

It is apparent that food safety risks can be reduced if food safety hazards are identified at an early stage and is followed by proper management actions to prevent the hazard to develop into an unacceptable level of risk. Many information and monitoring systems on food safety have been put in place, both nationally and internationally, which has been reviewed recently by Marvin *et al*. These authors divide early warning systems into three main categories:

1. Reactive systems which are endpoint or hazard focused,
2. proactive predictive systems (often referred to as emerging risk systems), and
3. systems based on a holistic approach. This category of systems uses information from inside and outside the food production chain to predict the emergence of a food safety risks.

 doi:10.1016/B978-0-12-378612-8.00319-X

Reactive Systems

The vast majority of the early warning systems in place fall into the first category: reactive early warning systems. These systems collect, analyze, and interpret data from running monitoring and surveillance programs and can be either hazard or disease recording systems. Hazard-focused systems focus on the identification of hazards as they occur in the food production from farm to fork. A typical example is the European Rapid Alert System for Food and Feed (RASFF), which is used by its members for notifying hazards to food and feed safety that they have identified and that are relevant to the other members as well. These members include the national food safety authorities of EU member states and associated countries, as well as the European Commission, which hosts the system. The notifications usually contain information obtained from food inspection and monitoring programs and cover many different kinds of hazards in food and feed, such as microbiological and other biological hazards, chemical contaminants and residues, physical hazards, and fraud-related issues. Both food and feed products are included in the RASFF system. The system also contains information on the origin of the product, the level of contamination, the risk management actions that have already been taken, and to which extent the product has already been distributed or not. A previous investigation examined the possibility of using trends in RASFF data for the purpose of identifying potentially emerging food safety issues. The authors found that the EU and national authorities had already responded with risk management measures in the cases identified, which also highlights important contribution of the system to adequate risk management of food safety.

Foodborne disease outbreak monitoring systems includes health surveillance and other epidemiological tools, such the electronic notification system for animal diseases (World Animal Health Information System) set up by the World Organisation for Animal Health (OIE). National veterinary authorities inform OIE of the occurrence in their country of animal diseases from a list of notifiable diseases in the frame of the terrestrial animal health code and the aquatic animal health code. This network has global dimension involving veterinary offices from its 175 member countries. Another example of disease monitoring system that functions as an early warning system is the European Centre for Disease Control (ECDC). This institution was established in 2004 to support the control of communicable diseases and other serious health threats, and is among others, based on input from national health protecting agencies of the EU member states. It also coordinates EU-wide surveillance networks for foodborne pathogens, and links to international initiatives in this field. The activities of the Enter-Net network for detection of international outbreaks of salmonellosis and verocytotoxin producing *Escherichia coli*, for example, was continued within the ECDC's Food and Waterborne Disease Unit. Enter-Net, which was a continuation of the previous Salm-Net network, was able to identify various international outbreaks related to specific serotypes of pathogens identified via pulse-field gel electrophoresis. PulseNet International is an example of an international network on foodborne pathogen-related disease surveillance in which ECDC participates. This network provides protocols for the subtyping of pathogens under surveillance, such as *Campylobacter jejuni*, *E. coli* (O157:H7 and non-O157), *Salmonella*, *Shigella sonnei*, *Listeria monocytogenes*, *Vibrio parahemolyticus*, and *Vibrio cholerae*, which allows for standardization and comparison of deoxyribonucleic acid (DNA) profiles of pathogens across participating laboratories. Using these protocols, a number of outbreaks have been linked to contaminated products and sources of contamination. These and similar networks for pathogen surveillance are also reviewed by Kleter and Marvin.

Proactive Predictive Systems

Proactive predicting early warning systems, however, are not focused on existing public health threats but are aiming to predict food safety risks that may emerge in the (near) future. Examples of such systems that are hazard-specific include the mycotoxin warning systems and the forecast system for harmful algal blooms, which produce marine biotoxins that can accumulate in shellfish and other seafood, based on satellite imagery, observations by workers in the field, computer models, and laboratory analysis. Other systems are more broadly oriented such as 'horizon scanning,' and information collecting systems, such as the Global Information and Early Warning System on Food and Agriculture run by Food and Agriculture Organization (FAO) or European Media Monitor (EMM) operated by the Joint Research Centre (JRC) in Europe. In the following section we will discuss the recently published study of the Emerging Risk (EMRISK) Unit of EFSA, which evaluated the applicability of EMM as an early detection tool for food and feed hazards.

New Developments and Improvements

The role of the early warning systems in the process of risk analysis, mentioned in the previous section, can be to aid the identification of hazards that need further being assessed scientifically for the actual risks involved and that also need being managed so as to prevent or mitigate the risks, for example, by recalls of implicated products or the implementation of controls in the food supply. Moreover, monitoring programs could include measurement of early warning signals and detection of signals that signify potential emerging risks.

Various developments in the field of emerging food safety risks have recently taken place at the level of national authorities and international organizations. In the USA, for example, the US Department of Agriculture's Animal Plant and Health Inspection Service transformed its Center for Emerging Issues into the new Center for Animal Health Information and Analysis. The new center's activities include the scanning of open-source media for information on emerging animal diseases, including zoonotic diseases in livestock that can be transmitted to consumers, as well as the use of geospatial data and models to predict the spread of diseases and their economic impact. In addition, Food Standards Australia New Zealand commits itself to providing information on emerging issues to stakeholders, including consumers and food industry, for example, through the recently initiated Monitoring of

Emerging Issues Newsletter. Although recognizing the global dimension of the recent developments in the field of emerging food safety issue identification, in the section that follows we focus on the EU and the FAO/World Health Organization (WHO) as advanced examples of these developments.

Establishment of the EMRISK Unit of EFSA

As mentioned in the Section Food Safety and Rapid Alert Systems, EFSA was established by the General Food Law, Regulation (EC) No. 178/2002, in 2002. This law also provided directions on which activities and tasks EFSA had to perform, including the provision of independent, objective, and transparent scientific advice on food and feed safety, as well as a number of related fields, such as plant health, animal welfare, and environmental release of genetically modified organisms. Moreover, EFSA was supposed to collect data on food consumption, biological risks, contaminants, and residues, as well as to conduct scientific studies within the remit of its mission. The identification of emerging risks was also specifically mentioned as a task of EFSA's, namely in article 34 of the General Food Law. This article specified, among others, that EFSA should establish monitoring procedures in order to systematically retrieve information on emerging risks. Information that is received by EFSA as part of its activities should be used for this purpose as well. The General Food Law also mentions that EU member states and various EU-wide institutions are to be contacted with a request for relevant information in the case there is a suspicion of an emerging risk. After EFSA has evaluated the emerging risk, it should inform the European Parliament, the European Commission, and the EU member states.

To perform its tasks related to emerging risks, EFSA has established the EMRISK unit. This unit's activities include the collection of relevant data and monitoring of information sources, as well as the development of procedures for the analysis and evaluation of these data. It has oversight over a number of groups dealing with emerging risks, such as an internal task force that monitors data available to EFSA for emerging risks, and the EFSA Scientific Cooperation Working Group on Emerging Risks. The latter, for example, has identified indicators and information sources, including a range of EU institutions and global initiatives, that could be used for the monitoring for signals that flag up an emerging risk.

The EMRISK unit has also explored the possibilities of using various data sources for the identification of emerging risks, including the RASFF system, EMM (see the following section), and trade data. With regard to RASFF data, routine monitoring of these data was considered useful, and the unit has established a system for collecting and presenting RASFF data, including a geographical map which highlights RASFF alerts pertaining to products from a specific country. Trade data collected by EU and FAO were also considered useful, for example, to detect certain changes in the volume or nature of food and feed products entering the EU. Such data, if combined with other data, could then be used for the identification of emerging risks. The unit has also established a Stakeholder Consultative Group, which contains experts with a wide-ranging experience in the fields of food and feed safety and stakeholders covering the whole food manufacture chain. It is considered that these stakeholders can provide useful data on emerging risks. The EMRISK unit also leads scientific projects on emerging risks, including a recently initiated project on the impact of climate change on the occurrence of aflatoxin B1 in cereals.

The EMM

The European Commission's JRC has developed a software tool (EMM) that collect publications and reports from news portals worldwide that are available through the World Wide Web. The system retrieves real time over 40 000 reports on a daily basis in 43 languages from more than 4000 websites from 1600 key news portals, 20 commercial news feeds, and some specialist sites. The collected information is classified, filtered, aggregated, and alerts are issued and presented in a user friendly manner via graphs, maps etc. EMM contains four portals, the NewsBrief, the NewsExplorer, the Medical Information System (MedISys), and the EMM-Labs. MedISys presents articles and reports related to public health, categorized into 100 different categories (e.g., diseases, symptoms, chemical agent, geographic regions, organizations, etc.) based on predefined keyword combinations and warns the user with automatically generated alerts. EMRISK has evaluated the work required to customize MedISys on food and feed hazard detection and to determine its performance as a monitoring and early warning system. The following evaluation was performed in this analysis:

- Identification of ways to increase the sensitivity of the system to food and feed hazards (i.e., category definitions and identification of gaps in media coverage).
- Evaluation of the efficiency of MedISys as monitoring tool (comparing reporting time of a hazard by MedISys with other systems such as the internet-based reporting system Program for Monitoring Emerging Diseases (ProMED-mail) and RASFF.
- Efficiency of MedISys as early detection tool using nine case studies (comparing timeliness between MedISys, ProMED-mail, and RASFF).

Comparing the monitoring data generated by MedISys, RASFF, and ProMED-mail in a fixed time frame (from January to April 2009) showed that MedISys was more successful and often earlier in retrieving food safety hazard reports than the other two systems. Only three of the ten hazards reported by MedISys were also notified in RASFF. This difference may be explained by the fact that RASFF is only reporting hazards on the European market. It was concluded that MedISys is an efficient monitoring and early detection tool, but its sensitiveness to food and feed hazards needs to be increased, for example, by developing multilingual categories related to food and feed.

Emerging Risk Systems based on a 'Holistic' Approach

A holistic host environment analysis of a series of food safety cases revealed that factors from outside the food production chain (such as human behavior, trade, climate, and

regulation) may directly or indirectly influence a food safety risk to develop. It was advocated that such factors should be taken into account when developing a proactive emerging risk identification system. With such an identification system, risks can be anticipated at an early stage of development so that timely preventive and/or mitigating actions can be taken in order to protect public health and abate negative effects in consumers. For this purpose, indicators have to be selected and measured within these influential sectors. A change in these indicators is a signal that flags up a potential development outside the food production chain that will eventually have its impact on food production and, consequently, food product safety. Also the inputs from experts are considered an important element in selecting indicators and determining whether signals warrant further follow up. Next, we describe an initiative toward the development of a system that mimics the reasoning of experts triggered by signals consisting of observed changes in indicators. This way, the system, once operational, can comprehensively scan a vast array of data.

In 2004, a team of researchers started a project called 'Emerging risk in the Dutch Food Chain' aiming to explore the potential of such holistic approach as a basis for an emerging risk identification system. Within this project a prototype system (called Emerging Risk Detection Support System (ERDSS)) was built. ERDSS is a knowledge-based system that uses expert knowledge and (external) signals (e.g., changes in a predefined indicator/database) to reason. The system mimics the reasoning of human experts using forward chaining to deduce new facts unknown using three basic elements: concepts (also known as things), facts (gives a meaning to a concept), and rules (often in the form of if–then rules). Once a new fact (e.g., change in a database, publication, etc.) is entered to ERDSS, the reasoning engine will use the expert knowledge (stored in the computer database as concept and facts) and reasoning rules to deduce new facts, some of which may be an emerging risk. The feasibility of this approach was demonstrated for salmon production. Risk managers in the Netherlands have recognized the potential of the ERDSS concept and it is foreseen that a functional working system will be developed in the near future using information data collected from the Internet as input to identify new emerging food safety risks.

International Exchange of Information: FAO/WHO

In the last years much effort has been given to the improvement of the information exchange on food safety-related issues between nations to combat the development and spreading of food safety risks.

FAO has recently established the Emergency Prevention System (EMPRES) Food Safety. Before that, it already had EMPRES systems in place for the detection of – and coordinated action against – transboundary threats to animal and plant health. For plant health, for example, the EMPRES system collects information on locust movement, whereas, for animal health, it does so for rinderpest, including the geographical dissemination of the pest or disease, as well as the preventive measures that are being taken. EMPRES also collects such information for a number of other plant and animal diseases, such as wheat stem rust and highly pathogenic avian influenza. EMPRES Food Safety is intended to act as a similar resource for food safety, not only identifying sources of potential food safety threats but also selecting those that require risk mitigation actions, and formulating strategies toward risk mitigation, whereas stimulating a dialog among the stakeholders involved and lending support to regional and national authorities in their risk management measures. Besides its cooperation with the animal and plant health components, EMPRES Food Safety will also collaborate with other institutions, such as the International Food Safety Authorities Network (INFOSAN) hosted by the WHO. The INFOSAN network aims to rapidly exchange information on food safety incidents and to share information of common interest to its members. It in turn has a relationship with the WHO Global Outbreak Alert and Response Network (GOARN), which focuses on human disease outbreaks. Other parallel global online initiatives through which health professionals report infectious disease outbreaks to each other include the International Society for Infectious Diseases' ProMED-mail and the commercial Global Infectious Diseases and Epidemiology Online Network (GIDEON) web application and database for health professionals, each with frequent updates. In addition, GIDEON also provides information on possible therapies to be applied, background information on microbial taxa and toxic substances in the workplace. The JRC's MedISys system, which also continuously provides updates on disease incidents, has been discussed in the Section 'The EMM' in more detail.

Conclusion

Both reactive and proactive early warning systems are in place that could be used for the identification of emerging risks to food safety. Several recent developments within the EU and at the global level of FAO/WHO indicate that there is an increased interest in developing proactive systems that use information from the Internet and from the environment of the food manufacture chain, i.e., the influential sectors linked with it, such as the ERDSS system.

PUBLIC HEALTH MEASURES

Monitoring of Contaminants

SJ Crossley, Food and Agriculture Organization of the United Nations (FAO), Rome, Italy
J Baines, Food Standards Australia New Zealand, Canberra ACT, Australia

Glossary

Contaminant It is a substance which is not intentionally added to food. It is present in food as a result of production (including operations carried out in crop husbandry, animal husbandry, and veterinary medicine), manufacture, processing, preparation, treatment, packing, packaging, transport, or holding of food or as a result of environmental contamination. The term does not include insect fragments, rodent hairs, and other extraneous matter.

Monitoring of contaminants The ongoing testing of food for the presence and concentration of contaminants.

Risk analysis A process consisting of three components: risk assessment, risk management and risk communication.

Introduction to Monitoring of Chemical Contaminants in Food

The presence and concentrations of contaminants in food is less predictable than that for chemicals resulting from human intervention, for example, food additives and pesticide residues, and direct information on expected levels in different food types is not usually available. Monitoring of these contaminants in the food supply is, therefore, crucial in order to assess any potential risk to food safety and provide information to underpin risk management responses.

Food chemical contaminants include, but are not confined to, the following classes: heavy elemental metals, naturally occurring toxicants (e.g., cyanogenic glycosides, mycotoxins, and biotoxins), and radionuclides. Contaminants frequently arise from environmental sources during the growth of the food. In some cases, human activity has added to the natural levels of environmental contamination, for example, dioxins, PCBs, radionuclides, and heavy metals.

Food can be contaminated with certain chemicals by the action of microorganisms, for example, the growth of two *Aspergillus* species on food can result in production of aflatoxins, which are of toxicological concern. Chemical contaminants can also result from the processing of food, for example, acrylamide is formed when some foods are prepared/cooked at high temperatures or result from other stages in its production, packaging, transport, or holding. Occasionally, chemical contamination can result from tampering or the deliberate addition to foods, for example, the addition of melamine to milk in China.

The Role of Monitoring in Risk Analysis

Risk analysis comprises three components: risk assessment, risk management, and risk communication. The risk assessment component for a hazard in food has the following four subcomponents: hazard identification, hazard characterization, exposure assessment, and risk characterization.

The dietary exposure assessment of food chemicals is the qualitative and/or quantitative evaluation of the likely intake of a chemical agent via food with exposure from other sources considered relevant. In the case of food chemicals, dietary exposure assessment takes into consideration the occurrence and concentrations of the chemical in the diet, consumption patterns of the foods containing the chemical, and likelihood of consumers eating large amounts of the foods in question (high consumers) and of the chemical being present in these foods at high levels. Usually, a range of intake or exposure estimates will be provided (e.g., for average consumers and for high consumers) and estimates may be broken down by subgroups of the population (e.g., infants, children, adults, and gender).

Monitoring data on the concentration and distribution of contaminants in food, therefore, provide a crucial input into the dietary exposure assessment component of the risk assessment. In the absence of monitoring data, the exposure assessment may have to rely on worst-case assumptions or may not be possible to undertake.

Types of Government Monitoring Activities and Other Considerations

National governments of developed countries, and many developing countries, have established monitoring programs to provide information on which regulatory decisions are made, including the establishment of food standards.

Food standards that aim to control contaminant levels by setting maximum levels (MLs) as a risk management measure are usually established for two reasons. MLs may be set for those foods that are known to be a major source of dietary

exposure to the contaminant (e.g., cadmium in potatoes) and/or for foods that may be consumed in small quantities by the general population but have high concentrations of the contaminant such that individual high consumers may be at risk (e.g., cadmium in liver and kidney). As a general principle, regardless of whether or not an ML exists, the levels of contaminants and natural toxicants in all foods should be kept as low as reasonably achievable (the as low as reasonably achievable (ALARA) principle).

The type of monitoring and surveillance of contaminant levels in food undertaken will depend on requirements to evaluate national food standards and/or monitor imported food, local knowledge about contaminants likely to be in food, the need to assess the presence of newly identified contaminants in food, analytical capability, capacity to use biomonitoring, and the resources available.

Ongoing Monitoring versus *Ad Hoc* Surveillance

The decision to undertake ongoing monitoring of the food supply as well as *ad hoc* surveillance by a government will depend to a large extent on government support and resources available for food collection, analysis, and regular reporting of results, as well as public expectations. The establishment of an ongoing system also requires the identification of key contaminant/food combinations to track, based on the available information. The reasons for *ad hoc* or less regular surveys will vary. For example, a total diet study may be undertaken every few years or in response to a contamination incident.

National Monitoring Surveys

The main aim of national monitoring surveys of the food supply is to collect concentration data on contaminants and other food chemicals, such as pesticide and veterinary drug residues, to assess if samples are in compliance with national legislation. The representativeness of the samples included will vary with the purpose of the survey and resources available, because ongoing surveys are expensive to maintain. For example, in the UK, the national food surveillance survey runs via an independent committee to give credibility to the data and covers contaminants and pesticides. By contrast, in Australia, the National Residue Survey of agricultural chemicals and contaminants is supported by the government and certain sectors of the food industry that export produce. Hence, sampling tends to reflect food from these sectors.

Total Diet Studies

Countries may opt to run total diet studies (TDSs) in addition to national monitoring surveys. The main aim of TDSs is to assess chronic dietary exposure to food chemicals by analyzing selected foods in the form commonly eaten by the population of interest, i.e., 'as consumed.' Published results include chemical concentration levels for the foods analyzed as well as estimated dietary exposures and contributions to that exposure from different foods. However, the food lists for TDSs are often limited to 80–200 foods, with analytical results 'mapped' to similar foods to estimate exposure from the whole diet. For example, concentration data for strawberries might be assigned to all berries consumed. An alternative approach used is to composite similar foods before analysis to reduce analytical costs.

WHO GEMS/Food Program

Since 1976, the Global Environment Monitoring System–Food Contamination Monitoring and Assessment Program (GEMS/Food) has informed governments, the Codex Alimentarius Commission (Codex), and other relevant institutions as well as the public on levels and trends of contaminants in food, their contribution to total human exposure, and significance with regard to public health and trade. The program is implemented by the World Health Organization (WHO) in cooperation with a network of more than 30 WHO Collaborating Centers and recognized national institutions located all around the world. The GEMS/Food program also involves national experts in more than 100 countries working to collect and analyze data and information to support the food risk assessment process.

Several important streams of data related to food consumption and food contamination are included in GEMS/Food:

1. Concentration of chemicals in food: Database on the level of chemicals in raw food commodities as well as in food consumed by final consumer.
2. Per capita food consumption: The GEMS/Food Cluster Diets based on similarities between dietary patterns of different countries and dietary patterns derived from Food and Agricultural Organization of the United Nations (FAO) food balance sheet data.
3. Individual food consumption: Compilation of individual levels of food consumption for average and high consumers on the basis of national surveys. This information is used mainly to assess exposure to food chemical presenting a potential acute risk to human health.

Food contamination monitoring is an essential component of assuring the safety of food supplies and managing health risks at the international level. The GEMS/Food database is open to competent authorities to submit and share their data on food monitoring and surveillance. Data are checked for consistency and completeness before being accepted by the WHO. Hence, GEMS/Food provides reliable information for setting priorities for consideration by Codex.

Within Codex, the chemical contamination of food is addressed by the Codex Committee on Contaminants in Food (CCCF). Risk management decisions are highly dependent on comparable and reliable exposure assessments, and GEMS/Food has provided assistance on a range of chemical issues to CCCF as well as the Joint Expert Committee on Food Additives (JECFA), the FAO/WHO scientific expert body with respect to contaminants in food.

Sampling Considerations

There are two types of monitoring and surveillance data: random and targeted. Targeted data are often collected from

foods likely to contain the contaminant of interest in response to specific problems that enable a quick risk management response to be taken. However, targeted data should be used with caution to estimate dietary exposure for use in risk assessments, as they may not be representative of all the food available for sale. For this reason, random sampling is preferable for these purposes. This is particularly true for acute dietary exposure assessments, as the fact that only a small proportion of any commodity entering the food chain is tested, means that there are significant limitations in ensuring the potential range of contaminant levels captured.

Contaminant data from monitoring and surveillance on food samples that are closer to the point of consumption in the food chain generally provide a better characterization of chemicals in food as purchased or eaten by consumers and hence provide a more accurate estimate of dietary exposure. Such sampling, therefore, accounts for chemical changes during transit, processing, and storage. Total diet studies are unique in that foods are prepared 'as consumed' before analysis, for example, meat is cooked and vegetables boiled, roasted, or fried according to local custom, if not usually eaten raw.

Deliberate contamination may elicit a more immediate response with targeted surveys necessary to determine the extent of the problem before developing an appropriate risk management response. For example, during the melamine incident, MLs for melamine were established by some countries on the basis of risk assessments, such as that undertaken by an FAO/WHO expert meeting, where available monitoring data, both from clinical cases and food analysis, were used. An example of a country's response to this incident has been described for Australia, where foods likely to be imported from China and foods containing milk powder were targeted for surveillance, for example, chocolates, biscuits, confectionery, and milk based beverages.

Analytical Testing Issues

In general, it is preferable to use the most sensitive method of analysis available, with the lowest level of detection as these data are more useful for dietary exposure assessments. However, the purpose of the monitoring program needs to be noted by the data user because some monitoring programs are designed to measure compliance with a given standard only and may, therefore, not use the most sensitive methods of analysis. Concentration levels in the food as consumed may not be reported if marker organs are used. For example, levels of heavy metal contamination may be analyzed only in the liver, rather than muscle meat.

Monitoring of Imported Food and Compliance

Some countries have extensive import food monitoring programs to test compliance with national food regulations, often deemed to be important where a large proportion of food consumed is imported. For example, in Hong Kong and Singapore, food regulatory agencies publish food monitoring results on a daily basis.

In other countries, a risk-based approach may be established on the basis of risk assessment information, as a means of prioritizing resources, such that foods with higher risk of chemical or microbiological contamination are tested for compliance at a higher rate than low-risk foods. For example, in Australia, 100% of consignments of high-risk foods are initially tested at the border, whereas only 5% of low-risk foods are tested on a random basis.

Biomonitoring

Biomarkers of exposure to food contaminants include biological changes to the body that are measurable, subclinical, and reversible and therefore do not depend on either food consumption or concentration data because they are 'downstream' from consumption. However, this means that the source of exposure cannot necessary be determined from the biomarker levels, that is, whether it is from the diet or other sources such as smoking or occupational activities. Although biomarkers can be used to assess if control measures have been effective in altering exposure levels for a given population, it is often difficult to interpret results or characterize the relationship between biomarker levels and health risk.

Increasingly, countries are looking to include biomedical surveys in conjunction with national nutrition surveys, for example, the US National Health and Nutrition Examination Survey (NHANES), the Canadian Health Measures Survey, the Australian Health Survey, and the New Zealand Nutrition Survey. These surveys could, in the future, provide a valuable data source for assessing exposure to contaminants. Blood and urine samples are normally obtained from individuals in these surveys for testing for chronic disease factors and nutritional status. In some cases, tests for environmental chemicals are already undertaken in addition to the standard health-related tests, for example, more than 600 chemicals are now tested in the NHANES survey, which expanded in 1999 to include more environmental chemicals and more than 200 in the more recently established Canadian biomedical survey. It was data derived from early NHANES that provided the first concrete evidence that among Americans blood levels of lead were increasing. As a result, the Environmental Protection Agency called for a reduction in production and sales of consumer products containing relatively large amounts lead, most notably gasoline and household paints. The UK Biobank is different in that it is an independent program collecting additional samples such as saliva as well as blood and urine. Also, from 2012, the Biobank is open to application from researchers to study these samples.

Human milk has long been recognized as a unique biological matrix, and the WHO, through the GEMS/Food program, has monitored levels of contaminants in human milk over several decades, in particular persistent organic pollutants (POPs). These chemicals are recognized as a good example of exposure biomarkers as they are known to accumulate in the food chain. Human milk monitoring, therefore, gives information about POPs in the environment and our bodies.

National Government Programs for the Monitoring of Food for Contaminants

National governments undertake a range of monitoring activities. These monitoring activities serve a number of

different purposes as outlined above, including the identification of emerging issues, data generation for risk assessments, and facilitation of prioritization of enforcement activity. Some examples of these national monitoring activities are given.

European Union

The European Union has a comprehensive set of monitoring and import controls for chemicals and microbiological hazards in food. The official controls are undertaken primarily by the relevant competent authorities of the member states and are laid down in a number of regulations relating to both food of animal and nonanimal origin. The Food and Veterinary Office check compliance with the requirements and contributes to the implementation of effective control systems.

With respect, specifically, to contaminants, the basic principles are in Council Regulation 315/93/EEC of 8 February 1993. MLs are set for the contaminants of greatest concern to EU consumers, due to either their toxicity or their potential prevalence in the food chain. These include aflatoxins, heavy metals (such as lead and mercury), dioxins, and nitrates and thus the MLs are set out in Commission Regulation (EC) No 1881/2006. These levels are set on the basis of scientific advice provided by the European Food Safety Authority (EFSA).

Other monitoring data are generated by member states in accordance with their own national priorities or as a result of European Commission recommendations. For example, for acrylamide, such a recommendation requests further investigations into the production and processing methods used by food producers in cases where high levels of acrylamide are found in the testing.

US

In the US, since the early 1960s, the key program of the monitoring of contaminants in food is the Total Diet Study conducted continuously by the US Food and Drug Administration (FDA). This involves the analysis of a group of foods that reflect the average food consumption patterns of a given population. Results of the analyzes are then used to estimate the average dietary exposure of contaminants from eating those foods. This information also provides a tool for supporting the regulatory actions and, over time, tracking the impact of the regulations. The FDA is generally responsible for testing imported food.

The US FDA also conduct a number of discrete surveys targeted at specific contaminants. For example, an exploratory survey of perchlorate in range of food and beverages was undertaken in 2004–05 and a dietary exposure assessment was undertaken using this data.

However, the testing of imported meat and poultry for contaminants is undertaken by the Food Safety and Inspection Service of the US Department of Agriculture.

Canada

Health Canada assesses the risks posed to Canadians by environmental contaminants in food. In support of these risk assessment activities, scientists monitor the concentrations of various environmental contaminants in foods through Canada's ongoing Total Diet Study. A number of other contaminant surveys are undertaken by Health Canada, such as the ongoing Human Milk Survey, which has the goal of examining the exposure of Canadian infants to a variety of contaminants, chemicals, nutrients, and immunoprotective constituents in breast milk. When necessary, Health Canada sets MLs for contaminants in foods.

Testing of food for contaminants is also undertaken by the Canadian Food Inspection Agency. For example, in 2010–11, 628 samples were collected and analyzed in a targeted survey of aflatoxins in dried fruits, nuts and nut products, and corn products.

Australia and New Zealand

Food Standards Australia New Zealand (FSANZ) in Australia, the Ministry for Primary Industries in New Zealand, and other government agencies monitor the food supply to ensure that it is safe and to ensure that foods comply with food standards.

The analytical testing of contaminants in food occurs either as specific discrete surveys, as periodic analytes in national Total Diet Studies, or as part of compliance activities. An example of a specific discrete survey would be the Australian survey of polycyclic aromatic hydrocarbons in food conducted by FSANZ in 2010.

Japan

Japan has a comprehensive monitoring scheme in place for imported food inspected by the Imported Foods Inspection Services. The published list of tests to be applied to imported food in 2012 includes a number of contaminants, for example, mycotoxins and shellfish toxins in specified foods.

Japan also undertakes monitoring of domestically produced food. This has included radionuclides in food. Japan implemented an enhanced monitoring program following the damage to the Daiichi nuclear power plant in Fukushima. In the year following the event, more than 120 000 food products were tested, predominantly meat and fishery products and vegetables, and the total number of cases that exceeded the provisional regulatory limit of 500 Bq kg^{-1} was 1162.

Emerging and Developing Countries

Other countries undertake the monitoring of contaminants in food. However, the size and scope of the monitoring programs varies considerably between countries. In some developing countries with limited economic and laboratory resources available, very little monitoring of contaminants in food is undertaken. In contrast, a number of emerging economies have extensive monitoring programs.

Case Studies – The Use of Research and Monitoring Data for Contaminants in the National Government Management of Food Safety Risk

Methylmercury in Fish

Mercury is released into the environment from both natural and anthropogenic sources and occurs in food as methylmercury or organic mercury. Health-based guidance values have been set for methylmercury, for example, a provisional tolerable weekly intake of 1.6 μg kg^{-1} body weight (bw) was set by JECFA in 2006 and a tolerable weekly intake of 1.3 μg kg^{-1} bw, expressed as mercury, was set by EFSA in 2012.

As for many other contaminants, it is important for governments to generate monitoring data to help to inform the development and review of risk management strategies for restricting methylmercury in the diet. The aim would be to ensure that potential exposures to methylmercury do not exceed the health-based guidance values.

Fish and seafood are the major source of methylmercury in most populations, with predatory and long-living fish such as marlin, swordfish, shark, ling, pike, and rays having the highest concentrations. Typically, governments may set MLs for fish and seafood and/or develop advisories on fish consumption. An additional risk management measure may be to restrict the sale or size of some species, the latter because mercury content increases with age of fish, assuming the size of the fish is a proxy for age. However, it is a complex risk management decision because fish are considered a good source of some nutrients (in particular protein, omega-three fatty acids, and iodine) and are low in saturated fat. So populations, especially pregnant women, are often encouraged by health professionals to regularly include fish in their diet. Although food standards can be set to restrict the level of methylmercury in fish, it is undesirable to set them so low that it restricts availability of fish in the market place. As a result, although food standards for MLs for total mercury or methylmercury can be set at an international (Codex guideline) or national level, they do not necessarily protect high or regular consumers of fish and seafood.

It is, therefore, important that governments monitor the effectiveness of the selected risk management strategies, particularly for vulnerable populations such as young children and pregnant women, and communities with high fish consumption levels. The effectiveness of food standards can be evaluated via regular monitoring surveys and total diet studies. Laws restricting fish size for sale are increasingly difficult to monitor and enforce as more fish are caught and processed at sea before sale at market.

At an international level, contaminant data are collated by the WHO GEMS/Food Program. The concentration data obtained from the monitoring surveys can then be used to estimate dietary exposure to total mercury, inorganic mercury, and/or methylmercury as part of the total diet study or other risk assessment process.

An example of monitoring data reported by EFSA from various countries is given in Table 1.

Available monitoring data on mercury or methylmercury levels in specific species of fish and seafood are critical to developing appropriate advisories on fish consumption. The concentration data are first combined with national food consumption data to give dietary exposure estimates for methylmercury from each species of fish, and then the number of serves of different types of fish that can be consumed per week or per month is calculated, taking background exposure from other foods into account. Consumption advisories vary with country because fish consumption habits and fish species differ between countries. For example, the USA, Canadian, Japanese, UK, and Australian governments have issued advisories highlighting the fish species relevant to their own populations that are of concern at high level of consumption.

Table 1 Range of total mercury and methylmercury reported in fish and shellfish from European countries, Canada, China, Ghana, Hong Kong, India, Malaysia, Papua New Guinea, Persian Gulf, and the USA

Type fish/seafood	*Total mercury μg kg^{-1}*	*Methylmercury μg kg^{-1}*
Freshwater fish	10–2 950	5–2 630
Marine fish	0–18 000	0–16 000
Shellfish	40–830	2–220

Evaluating the effectiveness of advisories requires quantitative and/or qualitative consumer research to assess whether the message has been received, understood, and implemented in people's lives. An example of a national advisory is given in Table 2.

Acrylamide in Certain Cooked Foods

Acrylamide is an industrial chemical whose primary use is the synthesis of polyacrylamide. In April 2002, the Swedish National Food Administration and researchers from Stockholm University announced their findings that acrylamide, a toxic and potentially cancer-causing chemical, is formed in many types of food prepared/cooked at high temperatures. As a result of concern expressed by member countries, an expert Consultation was convened jointly by the FAO and the WHO in June 2002.

The FAO/WHO Consultation concluded that the information on the levels of acrylamide in food (i.e., monitoring data) is far from complete and the magnitude of the cancer risk posed by acrylamide in food could not be quantified. Nevertheless, the consultation recommended a number of principles aimed at reducing the risk, for example, food should not be cooked excessively.

Following the consultation, research confirmed that the primary mechanism of formation is the Maillard Reaction of glucose and/or fructose with the amino acid asparagine, during heating. In the subsequent years, research has focused on generating monitoring data to determine levels in foods and toxicological studies to better characterize the hazard.

Monitoring data have been generated by a large number of countries in wide range of foods. A high level of variability in the levels of acrylamide has been found in individual foods, reflecting different formulation and processing conditions. In addition, the acrylamide levels vary with product, manufacturer, and country.

Table 2 Australian advice on mercury in fish (last updated September 2011). Number of serves of different types of fish you can safely eat

Pregnant women and women planning pregnancy	*Children (up to 6 years)*	*Rest of the population*
1 serve equals 150 g[a]	1 serve equals 75 g[a]	1 serve equals 150 g[a]
2–3 serves per week of any fish and seafood not listed below		2–3 serves per week of any fish and seafood not listed in the column below
OR		OR
1 serve per week of orange roughy (sea perch) or catfish and no other fish that week		1 serve per week of shark (flake) or billfish (swordfish/broadbill and marlin) and no other fish that week
OR		
1 serve per fortnight of shark (flake) or billfish (swordfish/broadbill and marlin) and no other fish that fortnight		

[a]A 150 g serve for adults and older children is equivalent to approximately two frozen crumbed fish portions. A 75 g serve for children is approximately three fish fingers (Hake or Hoki is used in fish fingers). Canned fish is sold in various sizes, for example, the snack size cans of tuna are approximately 95 g.

Table 3 Typical monitoring levels of acrylamide in example foods

Food	*Acrylamide concentration ($\mu g\ kg^{-1}$)*
Potato chips (crisps)	117–4215
French fries (potato chips)	59–5200
Bakery products and biscuits	18–3324
Bread	<10–397
Breakfast cereals	<10–1649
Chocolate products	<2–826
Roasted coffee	45–935
Coffee extract/powder	87–1188

In Europe, the EFSA have been publishing annual reports of acrylamide monitoring for several years. In a consolidated report for 2007–10 twenty-five European countries submitted a total of 13 162 acrylamide results. A similar monitoring research effort has been undertaken by many other countries, the USA, New Zealand and China. Typical monitoring levels of acrylamide in example foods are given in Table 3.

National monitoring levels have been used by the JECFA, the EFSA, and national governments to conduct dietary exposure assessments. At its 72nd meeting, the JECFA calculated mean dietary exposure to be 0.001 mg kg^{-1} bw day^{-1}, leading to a margin of exposure (MOE) of 180 and 310 for Harderian gland tumors in mice and mammary tumors in rats, respectively. The JECFA concluded that these MOEs indicate a health concern, a conclusion that could not have been reached in the absence of monitoring data.

Conclusions

Monitoring data for contaminants in food are important in allowing the assessment of the risk posed by these contaminants in the diet. These data also play a crucial role in establishing appropriate food standards and ensuring compliance with these standards. Many national governments have extensive monitoring programs for contaminants in food.

Assessment of Novel Foods and Ingredients

SU Fabiansson, Castlecrag, NSW, Australia

Glossary

Allergen Any substance that can cause an allergy.
Antinutrient Natural or synthetic compounds that interfere with the absorption of nutrients.
Bioactive compound Inherent non-nutrient constituent with anticipated health promoting/beneficial and/or toxic effects when ingested.
Genetic modification The direct manipulation of an organism's hereditary information using biotechnology.
Glycoalkaloid A family of poisons commonly found in nightshade plant species.
Nanotechnology The manipulation of matter with at least one dimension sized from 1 to 100 nm.
Superfruit A marketing term referring to a fruit which combines exceptional nutrient richness and antioxidant quality with appealing taste.
Toxin A poisonous substance produced within living cells or organisms.

Introduction

New foods or foods with new ingredients are introduced in their thousands each year to worldwide supermarket shelves, but are they novel? At first glance such a question seems to involve a tautology and requires an explanation.

First to the definition of new that in some dictionaries are specified as 'not existing before; made, introduced, or discovered recently or now for the first time.' With this definition most of the 'new' foods presented to customers are not new at all. They might be a mix of two existing products with some spices added, ready to cook, or just presented in new packaging material or a new package size for convenience. But they are basically the same food as before. New to the customer but not to the food safety risk manager (Figure 1).

So what about novel? Here the dictionaries have much the same definition specifying it as 'new and not resembling something formerly known or used, original or striking especially in conception or style.' This is not surprising because they both relate to the Latin *novellus,* with the diminutive of *novus* through the Old English *nīwe.* But in the food area there is a clear distinction between what is new and what is novel with novel foods or food ingredients captured in some specific national or regional legislation requiring authorization before being introduced into the market. However, as will be seen, a distinction between new and novel is not always easy to make.

In most countries, general food law requires that all food should be safe for consumption, novel or not. In the USA, the concept 'generally recognized as safe' by qualified experts is used. Although very few traditional foods and food ingredients in the market have been the subject of systematic toxicological or nutritional assessments, they are generally regarded as safe to eat because of their long history of use without evidence of harm when applying customary preparation methods. This is despite the fact that the food may contain antinutrients, toxins, or allergens that may require special knowledge of preparation or processing methods for safe consumption. Such knowledge has been built over their long history of use.

The introduction of novel foods or food ingredients in a market where they are unfamiliar or the use of novel processes in food production might pose a problem in that their immediate safety cannot be assured. This has required the introduction of approaches to determine their safety. However, such tasks are not trivial in that toxicological paradigms most often require studies using levels of administration orders of magnitude above the anticipated real-life intake, which is not possible for ordinary food. Instead, a

Figure 1 The large range of new foods introduced annually onto supermarket shelves are not necessarily novel (Photo: Alalsacienne).

 doi:10.1016/B978-0-12-378612-8.00350-4

comparative approach has been developed for their safety assessment in that they are matched with similar traditional foods that have a history of safe use to prove substantial equivalence.

Novel Foods Defined in Legislation

The special focus on novel foods or food ingredients was initially in response to the appearance of genetically modified foods or ingredients in the market and clearly different food production technologies like the use of nanotechnology. There was also a concern that unfamiliar products promoted as healthy alternatives, like chia seeds and so called superfruits like goji berries, might have unintended effects. Lately products from cloned animals have been included in the novel food concept. However, although the previous specific examples are clearly novel alternatives, novel foods or food ingredients can be difficult to define in a legal sense. In a general sense they can be seen as a type of food or food ingredient that does not have a significant history of consumption or is produced by a method that has not previously been used for food. However, such a general definition poses significant problems in that it does not account for geographical patterns and differences in cooking traditions. Specific legislation in place in Europe, Canada, and Australia/New Zealand have all attempted to further define novel foods (Figure 2).

In Europe, novel foods were originally defined as all foods and food ingredients not used for human consumption to a significant degree within the European Union (EU) before 15 May 1997. Thus, the legislation includes a geographical and a time limitation. In addition, these foods and food ingredients had to fall into six categories:

- containing or consisting of genetically modified organisms (GMOs);
- produced from, but not containing, GMOs;
- with a new or intentionally modified primary molecular structure;
- consisting of or isolated from microorganisms, fungi, or algae; or
- consisting of or isolated from plants, or food ingredients isolated from animals, except for foods and food ingredients obtained by traditional propagating or breeding practices, and having a history of safe use; or
- include a production process not currently used, where that process gives rise to significant changes in the composition or structure of the food or food ingredient, which affects its nutritional value, metabolic effect or level of undesirable substances.

Figure 2 Chia seeds introduced as a novel food on new markets (Photo: Stacey Spensley).

Originally, the European novel food legislation was conceived in response to the arrival of food products derived from genetically modified crops, but these are now controlled under a separate regulatory regime.

In Australia and New Zealand novel foods are defined in legislation as nontraditional foods with no history of safe use. The characteristics of a food that make it novel means scientists cannot be certain they are safe to eat, so they are supposed to be rigorously assessed before being allowed to be sold. Novel foods are required to be listed in the Food Standard before they may be sold in Australia or New Zealand. This means that any food manufacturer wanting to sell a novel food or ingredient must ask for an amendment of the Standard to include it in the list. If the food passes a safety assessment the manufacturer can go ahead and sell it, so long as it complies with any conditions specified. A specific committee has been appointed to adjudicate whether or not a food or food ingredient is novel.

In Canada, novel foods are regulated under the Novel Foods Regulations. The regulations define novel food as products that have never been used as food, foods that result from a process that has not been previously used for food, or, foods that have undergone genetic modification and have new traits. There is a requirement that a company wanting to sell a novel food notify Health Canada before marketing or advertising the product. Premarket notification permits Health Canada to conduct a thorough safety assessment to demonstrate that a novel food is safe and nutritious before it is allowed in the Canadian marketplace.

Safety Assessment of Novel Foods and Food Ingredients

The general principles to be applied in the safety assessment of novel foods or food ingredients have been outlined internationally by the Organisation for Economic Cooperation and Development and the World Health Organization. They specify as a fundamental requirement that a rigorous, science-based risk assessment be carried out before putting novel foods and ingredients on the market. To facilitate such an assessment, a comparative approach should be adopted wherever possible to prove substantial equivalence with traditional foods that have a history of safe use. Although this principle was originally introduced for assessing genetically modified foods, the concept is feasible for all safety assessment of foods from novel sources and produced by novel processes.

In cases where detailed testing and analysis prove necessary it should focus on any potentially critical difference between the novel and the traditional food that could become a hazard. In this way, assurances are obtained that novel foods are

as safe as the traditional foods with which they are compared. Although not fully conclusive, it provides a pragmatic approach to assure relative safety.

If a food ingredient used as the source of a novel food has a history of safe consumption in traditional use then any toxicological concerns about proposed new uses are reduced. However, it is still important to evaluate the food production method and expected consumption patterns in detail because hazardous components might survive new industrial processes although it is of no concern in traditional use. The safety assessment should include analytical, compositional, and nutritional data as well as previous and predicted exposure and results from animal and human studies if appropriate.

If substantial equivalence to a traditional food can be proven and no new hazards identified this will be sufficient for introduction of the novel food onto the market. A postmarket survey might be required to confirm the preliminary conclusion. If doubts persist it will be necessary to conduct a risk assessment by identifying potential hazards and describing dose-response details. Public exposure to the hazard should be ascertained and the health impact of the risks posed by ingesting the hazardous substance at these exposure levels evaluated.

Identifying Public Health Hazards

To assess the safety of a novel food, initially it will be important to identify the traditional food to which it could be compared. If there is no similar food with a history of safe use a more elaborate safety assessment will be necessary. To document the history of safe use the Canadian guidelines requires proof of significant human consumption of food over several generations and in a large, genetically diverse populations for which there exist adequate toxicological and allergenicity data to provide reasonable certainty that no harm will result from consumption of the food. In the EU guidelines, information on past and present use of the food source in other parts of the world would be an essential piece of information required to assess the safety of the novel food. According to the Australia and New Zealand legislation foods or food ingredients may only be considered novel, if they are first considered nontraditional. The definition of 'nontraditional food' does not include foods produced using new processes or foods derived from novel sources unless there were some altered characteristics. An external panel has been set up to adjudicate whether or not a food is novel based on information supplied by the applicant.

Various databases can be used to help to establish whether a particular product has a history of safe use as a food or food source. These include national food survey reports and global, regional and national surveys of plant and animal products with food uses. If an equivalent traditional food exists with similar use, a comparison with the novel food is performed as a second step and includes chemical composition, methods of production and use, intake patterns, nutritional value, and target groups. The hazard identification should focus on antinutrients, toxins, bioactive compounds, and allergens.

Figure 3 There are as many as 5000 different varieties of potato around the world (Photo: US Agricultural Research Services).

Chaco Potato Example

Assume you wanted to introduce a new potato species currently not on your market called Chaco or *Solanum chacoense* in Latin, a wild relative of the cultivated potato to be used in a similar fashion to traditional potatoes. You definitely do not want to repeat the mistake made by the cooks of Queen Elizabeth I when Sir Walter Raleigh according to popular legend introduced potatoes for the first time to Ireland. Unfamiliar with the plant, they threw out the edible tubers and cooked the stems and leaves which contain high volumes of solanine. Everyone fell deathly ill (Figure 3).

Currently there are approximately 5000 potato varieties worldwide. Three thousand of them are found in the Andes alone, mainly in Peru, Bolivia, Ecuador, Chile, and Colombia. Apart from the 5000 cultivated varieties, there are approximately 200 wild species and subspecies of which you have settled on one because of its different taste and perceived benefits in coming from an extensive agricultural source without chemical inputs. You know that traditional potatoes naturally produce solanine and chaconine, a related glycoalkaloid, as a defense mechanism against insects, disease, and predators. A normal potato might have 12–20 mg kg^{-1} of glycoalkaloid content and this is no threat to public health. However, some noncommercial varieties can have much higher levels. This would typically be the hazard you have to study in detail during different growing and storing conditions.

Characterizing the Identified Hazards

Having identified a possible equivalent product to the novel food and potential hazards a detailed analysis should follow. The novel food and the traditional equivalent if available should both be fully characterized and results compared. This includes a precise biological identification using appropriate methodologies. The origin, geographical distribution, and genetic diversity of the food source should be described. For purified ingredients, focus should be given to chemical identity and potential impurities that could be formed or introduced during manufacture. Particular attention should be given to compounds that may have implications for the health

of more vulnerable population groups, which could include infants, children, elderly, and pregnant women.

The potential adverse health effects attributable to a specific hazard should be described, the mechanisms by which the hazard might exert its toxic effects should be detailed, and the associated dose, route, duration, and timing of exposure established. This should include the qualitative and, wherever possible, quantitative description of the inherent properties of the hazard or the situation having the potential to cause adverse effects. In addition, when feasible, a dose–response assessment and its associated uncertainties should be calculated.

Back to the Chaco Potato Example

Coming back to the Chaco example, you are aware that in general the glycoalkaloid compounds in potato plants are concentrated in leaves, stems, sprouts, and fruits. However, exposure to light, physical damage, and age will increase the glycoalkaloid content within the tuber itself. The concentration of glycoalkaloid in wild potatoes are often much higher than in cultivated potatoes because selective plant breeding has reduced the levels of glycoalkaloids in the latter.

Solanine poisoning is rare and in most cases benign but can become serious. You have to review the symptoms that might include nausea, diarrhea, vomiting, stomach cramps, burning sensation in the throat, cardiac dysrhythmia, headache, and dizziness. In more severe cases, hallucinations, loss of sensation, paralysis, fever, jaundice, dilated pupils, hypothermia, and death have been reported. It has been suggested that the toxic mechanism of solanine is caused by the chemical's interaction with mitochondrial membranes.

According to official statistics solanine in potatoes has killed at least 30 people and made over 2000 very sick over the years. Case history reports cover incidents in Cyprus and North Korea although the real number of cases dismissed as just ordinary gastroenteritis is probably much higher. It is believed that doses of 2 to 5 mg kg^{-1} bodyweight can cause toxic symptoms, and that doses of 6 mg kg^{-1} bodyweight might be a fatal threshold. Those will be your inputs for the risk characterization.

Estimating Exposure

Exposure assessment is the estimation of the likelihood that a consumer will be exposed to a substance and to quantify the extent of that exposure, when and if it occurs. To do so, exposure assessments combine data on concentrations of a chemical substance present in food with data on the quantity of those foods consumed. To be able to combine these different types of data it is necessary to consider standardization of associated metadata, in particular harmonization of the food description.

Exposure assessments are most often conducted at the general population level, but subgroups can also be explored that show particular exposure patterns, for example, due to a high level of consumption or particular physiological or pathological conditions. Assessments can be made either for acute or chronic exposure, where acute exposure is estimated for a period of up to 24 h whereas chronic (long-term) exposure covers the average daily exposure over several years or an entire lifetime (Figure 4).

Figure 4 Calculating exposure for the general population and subgroups of particular interest like children (Photo: Sean Dreilinger).

Exposure assessments are often performed according to the fit-for-purpose principle with the consequence that there is little harmonization across disciplines with each having their own agreed international guidelines. For potential hazards in novel foods it will be important to assess other sources of the same hazard to put the exposure into context. The actual exposure calculation for a novel food is simple in that it can focus only on the consumption of this food. However, the situation is a bit more complex for novel food ingredients because they can be used in the production of a range of different foods at different levels. Calculation of worst-case scenarios can be useful for such cases.

Chaco Potato Consumption

Potatoes were introduced outside the Andes region four centuries ago, and are now a common food all over the world. There is thus ample evidence of prior consumption among a variety of population groups without appreciable harm. The annual diet of an average global citizen in the first decade of the twenty-first century included approximately 33 kg (73 lb) of potato or an average of 90 g day^{-1}. However, the local importance of potato is extremely variable and rapidly

changing. It remains an essential crop in Europe (especially eastern and central Europe).

According to the food consumption statistics published by the European Food Safety Authority an average portion of potato for adults might roughly be estimated at 200 g whereas a high consumer might eat a portion of 400 g. At an average solanine level of 15 mg kg^{-1} in cultivated potatoes an average person would be exposed to approximately 0.05 mg solanine per kg bodyweight from a portion, which can double for high consumers.

Being a wild variety, average solanine levels in Chaco potato has been estimated to be approximately 150 mg kg^{-1}. This would result in solanine exposure of 0.5 mg per kg bodyweight from a portion for an average consumer and 1.0 mg kg^{-1} for a high consumer.

Risk Characterization

Risk characterization is the final phase of the food safety assessment process. It is in risk characterization that the results of the risk assessment are presented. This phase determines the probability of an adverse effect to a human population in consuming the novel food or food ingredient and outlines permissible exposure levels from which standards of exposure are set. These results are provided in the form of risk estimates and risk descriptions that provide answers to questions risk managers might pose during the authorization process or information necessary for the food producer in managing food safety.

Safety of Chaco Potato

Although commercially grown potatoes have a safety margin of at least 50 times between estimated exposure and the first signs of toxic effects, this would be reduced to five times for Chaco potatoes. A further review of Chaco potato consumption in the Andes region showed that this variety is mainly used as an appetizer and not for the main meal. Typical consumption levels would be limited to a portion of not more than 30 g. You thus propose to use your Chaco potatoes as a delicatessen only to be sold in small portion packs to reduce any threats to public health as much as possible.

Authorization Process

The authorization process will vary depending on the geographical region and the respective regulations in place. At a minimum the food producer must ascertain that in their own judgment the novel food or food ingredient comply with general food safety provisions. If the 'history of safe use' of a novel food or the traditional food used as a benchmark to assess the safety of a novel food can be sufficiently described, limitations identified, and the intended conditions of use are the same, then few further safety data should be required. If the novel food is taken out of the cultural, processing, and intended use context of the novel food or comparator, which provides its acceptable 'history of safe use,' then more safety data and a more rigorous evaluation may be required.

There are two possible routes to comply with the EU legislation for authorization of novel foods – a full application or a simplified procedure. A simplified application is possible when a national competent authority believes that the novel food or food ingredient is substantially equivalent to an existing food or food ingredient. In such cases the commercial company can just notify the European Commission of its intention to market the novel food or novel food ingredient. However, other member states are given an opportunity to object should they wish to do so. All other cases require a full application that is initially assessed at the national competent authority level with a recommendation for approval required by the Standing Committee on Food Chain and Animal Health.

Examples of novel products approved during 2012 include:

- Docosahexaenoic acid and Eicosapentaenoic acid-rich oil from the microalgae *Schizochytrium* sp. to be used in food supplements, cereal products, and spreadable fats;
- Synthetic vitamin K2 that essentially comprises all-trans menaquinone-7;
- Extension of the use of Antarctic krill oil to also include bakery products, nutrition bars, nonalcoholic beverages as well as milk-based drinks and dairy analog drinks.

An example of a rejected application cover the Nangai nut (*Canarium indicum* L.). It is native to Vanuatu. It was concluded that the nut was not previously consumed in the European Union and the requesting company, even after having been invited to submit a full assessment report, failed to do so.

In Canada, government scientists use data submitted by the companies seeking approval of their products to assess their safety. This data must be of the same high quality that is required by scientific journals for publication and peer review. The data are thoroughly analyzed, as are the rules used to ensure the validity of results. If the data is not scientifically sound, if it is incomplete, or if it is inadequate, government regulators require that the product developer address these problems before the assessment can continue. To date, more than 90 novel foods have been approved for sale in Canada including a number of canola, corn, cottonseed, and flax crop lines. Some of the novel traits include herbicide tolerance and pest and disease resistance. In spite of the benefits brought about by the development of novel foods, there are also a number of concerns that have been raised concerning their potential impact on the environment and on human health and safety.

In Australia and New Zealand, an Application Handbook assists the process of assembling required information for an authorization. It specifies a number of categories of novel foods with customized information for each. In general, an application should address the history of use as a food in other countries, the composition of the novel food, particularly the levels of antinutrients and naturally-occurring toxins and the method of preparation and specifications of a novel food ingredient. It should describe the potential for allergenicity of the novel food and present results from metabolism/toxicokinetic studies on the novel food ingredient, as well as animal toxicity studies and human tolerance studies.

Postmarket Monitoring

Once a novel product has reached the market it will be very important, when certain assumptions about its use were made, to follow up market penetration and potential negative reactions. This is commonly called postmarket monitoring and will provide additional reassurances regarding long-term safety of products, as well as their impact on the food supply. It is an additional tool to complement the premarket risk assessment when some uncertainties remain.

Postmarket monitoring should be used as a means of addressing specific questions to be useful. It could include an evaluation of actual intake of a food by target consumers deemed most at risk in the premarket assessment to increase the probability of detecting adverse health effects in everyday life. It is normally not a routine requirement for the approval of novel foods, but there are some examples when it might be necessary.

A commercial company requested authorization for the use of plant sterols in yellow fat spreads. It has since been expanded to cover other product types also. Plant sterols are structurally related to cholesterol and can be divided into phytosterols and phytostanols, the latter being the saturated version of the former. Scientific studies indicate that consumption of 1.5–3 g of plant sterols per day can significantly reduce the level of low-density lipoprotein cholesterol in individuals if consumed as part of a healthy diet. The products would target people with high cholesterol levels. Unfortunately, the consumption of high doses of plant sterols might also significantly reduce the blood levels of carotenoids. As a prudent precaution it has thus been suggested that intakes of plant sterols should not exceed 3 g day^{-1}.

As part of the approval process the applicant was asked to undertake postmarket monitoring to check whether or not products with added plant sterols were purchased exclusively by the target group and if multiple products were used by consumers increasing the risk of exceeding the 3 g per day of plant sterols. The research found that more than 60% of the consumers of food products with added plant sterols had high blood cholesterol levels and a large majority belonged to the over 45 age group. There was some leakage with whole families consuming the products without belonging to the target group, including a few children. However, reassuring authorities, that there seemed to be little over-consumption of food products with added plant sterols, rather the average consumer exposure to plant sterols was on the low side of what is considered an effective dose.

Even if not required by the authorization, postmarket monitoring is often used by industry on a voluntary basis to monitor the performance of novel foods or food ingredients in the marketplace.

PUBLIC HEALTH MEASURES

Food Defense: Prevention of Sabotage and Bioterrorism

M Hennessey and F Busta, University of Minnesota, St. Paul, MN, USA

Introduction

The world is challenged with nourishing a rapidly expanding population with increasingly limited resources. Although globalization of the food system offers many benefits, it also presents new challenges to safe food production and distribution. The increasing complexity of food supply chains, global nature of production, and widespread distribution of food products from a single manufacturing facility all increase the food supply to the potential of an attack.

The intentional contamination of food to cause harm, and the consequent concern of food defense, has a very long history. There are several examples of the military use of food contamination in the historical record. One such example includes the Athenian contamination of drinking water for the city of Kirrha with the plant root helleborus from 590 to 600 BC. This water contamination event reportedly caused severe gastrointestinal illness, rendering the city defenseless for the ensuing attack. The Carthaginian General Maharbal reportedly contaminated wine with mandagora, and there are various historic instances of plague infested animal/human bodies dumped into water and food supplies during Roman times. The Japanese army, during World War II is known to have experimented with the use of food as a delivery vehicle for several pathogens. These pathogens include *Vibrio cholerae*, *Salmonella enterica* serovar Paratyphi, *Shigella* spp., and *Yersinia pestis*.

For the purposes of this article, the following definitions will be used. Food security refers to access to sufficient calories to meet a population's demand. Food Safety is defined as the prevention of accidental hazards. Food defense refers to the prevention of intentional contamination. Food Protection is used as an umbrella term to encompass both food safety and food defense.

Intentional versus Unintentional Contamination

As stated previously, the food system is an extremely complex network of networks. Movement of food products is generally not linear, and products can move through multiple suppliers, warehouses, or distribution centers before reaching the final consumer. In such a complex network of systems, prevention of contamination of any kind, be it intentional or accidental, is a challenge.

When a contaminant of any kind can result in human illness, both intentional and unintentional acts are of concern. Extensive efforts have been undertaken by the food industry, government, and academia to address the food safety concerns associated with accidental contamination. However, food safety failures are still known to occur. A 2009 outbreak of *Salmonella* associated with peanuts was identified which ultimately led to more than 700 illnesses in 46 states. The company implicated had sold peanut butter products to more than 2100 accounts, and at least 431 peanut butter-containing products needed to be recalled from 54 different companies. Although food safety incidents can be anticipated as a result of system failure, the nature of intentional contamination is fundamentally different. Individuals who intentionally contaminate the food supply are purposefully trying to avoid the prevention and detection systems normally in place. In addition, individuals who are purposefully trying to cause harm will also be purposefully trying to avoid detection before the incident.

There are several actors to consider when looking at the risk of intentional contamination. These actors include the disgruntled insider, the disgruntled outsider, and an individual who is a terrorist. The motives of these three actors are different and should be considered when developing a food defense program. The motives of a disgruntled insider or outsider may be to cause brand damage to a specific company. This is a stark contrast to the motives of a terrorist. Terrorism, as defined by the Federal Emergency management agency, is the use of force or violence against persons or property in violation of the criminal laws of the United States for purposes of intimidation, coercion, or ransom. Terrorists are generally seeking to cause harm to a large number of individuals, rather than any specific brand damage to a company.

Risk Management

For either intentional or unintentional contamination of food, risk management strategy includes identifying the contaminant, risk or vulnerability of insertion of that contaminant, and subsequent insertion of controls to reduce the likelihood of the contaminant entering the food supply. The control strategies can be inserted at any point of the food chain, from production and preharvest inputs, through consumption. There are three control strategies which historically have been used for food defense. These include hazard analysis critical control points (HACCP), operational risk management (ORM), and the criticality, accessibility, recuperability, vulnerability, effect, and recognizability (CARVER) tool.

 doi:10.1016/B978-0-12-378612-8.00324-3

In general, modern food-producing facilities have been designed to control for the accidental introduction of known microbiological threats. The HACCP system, is one example of how threats which are deemed 'reasonably likely to occur' can be controlled. When considering intentional contamination, one begins with selection of the actual contaminants of concern, includes where and how they would be introduced, to what food, the level of introduction, and many additional factors. A one size fits all approach is difficult to apply when considering intentional contamination. One limitation to the HACCP-type approach is that HACCP programs are designed around hazards deemed reasonably likely to occur. Terrorism is an asymmetrical threat making it difficult to determine how and when a food terrorism event may occur. It is important to note, however, that the HACCP approach may also provide benefits to food defense.

ORM originated in the United States by the National Aeronautics and Space Administration and the United States Department of Defense. The purpose of ORM was to reduce the risk failure of aircraft, space missions, and weapons. ORM was adopted by the US Food and Drug Administration – Center for Food Safety and Applied Nutrition for early food system risk assessments. ORM is a five step process for identifying and managing risks. These five steps include indentifying the hazards, assessing the potential consequences of the hazard, determining which risks to manage and with which interventions, implementing the interventions, and finally assessing the success of interventions and modifying as necessary.

ORM is a function of the severity and the probability of the failure. For the purposes of food defense, probability can best be considered as the probability of success if an appropriately skilled person or group tried to contaminate the food system. For any unit of operation in the food supply, one can conduct the ORM analysis to compare the severity with the probability and focus interventions on where both of these factors are high. ORM has historically been used to reduce threats to food; however, in recent years ORM has been replaced by the new CARVER + shock methodology.

CARVER and the newer iteration of CARVER + shock is another strategy for completing food defense risk assessments. This tool is now used by both the Food and Drug Administration (FDA) and the United States Department of Agriculture (USDA). CARVER + shock risk assessment is composed of seven elements, which are used to evaluate the vulnerability of a system by analyzing each node of the system. Modified to address the concern of intentional contamination the seven elements are listed below.

- Criticality: the degree to which the public health or economic consequences are nationally significant. High scores equate to catastrophic morbidity, mortality, or economic harm.
- Accessibility: physical access to the target; the ability of the perpetrator to gain access to the point of contamination and escape undetected.
- Recuperability: overall system resiliency as measured by the time required to bring the system back into operation, with low scores for only days to recover and high scores for recovery going on a year or longer.
- Vulnerability: attack feasibility as viewed by the potential for a successful attack. This includes both the ability to introduce enough of a material of concern to cause harm and the potential for subsequent processing to reduce the risk.
- Effect: direct loss from the attack as defined by the fraction of the food system that has been impacted by the attack.
- Recognizability: ease of target identification is a measure of the degree of specialized knowledge needed in order to identify the point for the intentional contamination.
- Shock: combined health, economic, and psychological impact of the attack, which is a measure of the overall impact. Importantly, the economic and psychological impacts of an attack may not require any morbidity or mortality if they result in a substantial lack of public confidence in the food system or government.

Each of these seven steps is evaluated and a score for each element is assigned. A team of experts is generally required to complete this facilities evaluation. A composite score is then compiled. The score can then be used for comparisons across the section of the food system under consideration.

Assessing the risk through ORM requires less training than CARVER + shock and in some ways is simpler than CARVER + shock. ORM only uses two rating elements for ranking risk, the severity and the probability. In some cases, a combined approach uses both CARVER + shock, and ORM may be desirable. Once risks are identified, then a risk management approach such as HACCP may be incorporated into the facilities design.

Prevention Strategies

Preventing intentional contamination of food is difficult; however, there are several approaches one can take to deter an intentional food contamination event. In the private sector, several steps can be taken to reduce the threat. Some of the simplest steps include locking external entryways to facilities and limiting access inside buildings to only employees. Employee background checks can also be performed to identify any employee with a potentially suspicious history.

Employees should also only be allowed to access those areas of a facility in which they are assigned to work. Different colored clothing can be assigned to employees working in specific areas of a facility, thus making it easy to identify if an employee is out of his or her assigned area.

Industry best practices call for restricting access to dry ingredient storage. Access should only be allowed to those employees that are designated for that area. An observation system to further reduce the risk of contamination of ingredients is also beneficial. Entry requirements for increased physical security of facility are also necessary. Standardized entry and exit procedures should be adhered to, with checks and verifications of personal identification, equipment, and any other items entering the facility. Furthermore, locks should be used on all doors in a facility to limit access. Employees should all come through a common entryway, where credentials can be checked.

In the public sector, governments have also become increasingly aware of the potential threat of an intentional attack

on the food supply. The World Health Organization has published 'Terrorist Threats to Food,' which is intended primarily for policy makers in national governments with responsibilities for ensuring food safety and designed to assist them in incorporating considerations of food terrorism into existing food safety systems. The document received favorable comments from governments, the food industry, and consumers and has been one of the most requested WHO documents in the field of food safety. Within the United States, the Food and Drug Administration as well as the USDA both have developed groups looking specifically at food defense issues.

Food defense working groups have also been established in consumer organizations and food industry professional organizations. These working groups have served to initiate a dialogue among interested parties working to ensure the safety of the food supply from all possible threats. The private and public sectors both have roles to play in food defense, and both sectors have been taking steps to enhance food defense.

Summary

Intentional attacks on the food supply are not a new paradigm and present a very real and dangerous threat. Food has historically been used as a vehicle to cause illness, and it can be expected that food may continue to be used as a vehicle to cause illness in the future. What has changed is the potential footprint of an intentional attack on the food supply, due to the concentrated manufacturing with widespread distribution of food products. The modern food system is complex and rapidly changing, making it an attractive target for terrorism.

Building a robust food defense plan will also have the ancillary benefit of ensuring food safety. A good food defense program will ensure the health of the end consumer and will ensure a safe and abundant food supply for all.

Evaluation of the Efficacy of National Food Control Programs

WA Anderson, E O'Leary, D Cousins, R Evans, and A Reilly, Food Safety Authority of Ireland, Dublin, Ireland

Glossary

Monitoring Conducting a planned sequence of observations or measurements with a view to obtaining an overview of the state of compliance with feed or food law, animal health and animal welfare rules (European Food Law Definition).

Surveillance The continuous monitoring of the food supply to ensure consumers are not exposed to components in foods, such as chemical contaminants or biological hazards, which pose a risk to health (WHO definition).

Introduction

National food control programs (FCPs) are designed and implemented to ensure a high level of public health protection with respect to the food supply in a particular country. Their aim is to protect public health by providing a legal framework for the production, distribution, and sale of safe food, while facilitating the development of the food industry within a system of oversight by the competent authority. FCPs must cover all aspects of food production throughout the food chain from farm to fork, including both the domestic food industry and the imported food. Equity of treatment is an essential cornerstone of a fair FCP, where domestic and imported foods are subjected to the same risk-based controls. This ensures better protection of public health and facilitates global trade.

In practice, few countries actively design their whole FCP before its inception. Most FCPs have evolved over time around a basic legal framework using a combination of activities carried out by one or more state bodies. Generally, food control legislation and official control activities tend to expand in response to changes in technology, resource allocation, and emerging food safety problems. This trend for expansion can lead to inefficiencies over time and even reduce the effectiveness of the control program when resources are finite. Therefore, at some point in time the control program may need to be reviewed and, if necessary, a new framework developed. For example, after several decades of food law development in the European Union and after several well-documented food scares, it became necessary to redesign and simplify the legislative framework to reflect the modern food safety requirements and protect the consumer's health in a better way. The underlying principles of this redesign were articulated by the European Commission (EC) in the White Paper on Food Safety in 2000 and provide a good example of a reevaluation process.

As food safety programs develop and change, it is also essential that competent authorities evaluate their effectiveness to establish if they remain fit for purpose, to identify gaps and overlaps, and to enable the development of corrective action plans that can improve the protection of public health if implemented. This article provides an overview of methodologies used to evaluate the efficacy of national food safety control programs.

Essential Elements of an Effective National FCP

The basic elements of an FCP are the same today as earlier, a legislative framework combined with coordinated inspection of food businesses and testing of food to monitor safety and compliance. However, control programs have progressed over the past decades from hazard-based systems to risk-based systems, although this transition is still in progress around the world. Early FCPs were focused on the control of food hazards through the implementation of visual inspection of food premises and food-testing regimes designed to monitor microbiological and chemical contamination. They then progressed with the introduction of audits of food businesses, food safety management system, and testing of food that was linked, wherever possible, to the verification and validation of Hazard Analysis Critical Control Point systems.

Today, effective FCPs need to be based on risk control rather than hazard control. Food control systems that constantly focus on tighter controls to eliminate hazards tend to become burdensome for both the food industry and the competent authorities. Such programs increase the cost and complexity of compliance for food businesses and stretch the limited resources of the competent authorities by providing little basis for prioritization. Effective FCPs should ideally be designed with the risk analysis paradigm in mind. This concept has been defined by the Codex Alimentarius as consisting of three

interlinked elements; risk assessment, risk management, and risk communication.

Ideally, the risk assessment process should be independent of the risk management process to ensure transparency and fairness, for example, risk assessments provided by the European Food Safety Authority for the EC. The risk management function, which in the context of FCPs, consists of the development of food legislation and the monitoring and enforcement of food business compliance, should be based on science and informed by risk assessment. For example, in the context of food safety, legislation should be introduced only where it is necessary to control a risk to public health. Additionally, the requirements of food legislation should only be as stringent as necessary to control the risk, for example, microbiological criteria that tolerates low numbers of *Listeria monocytogenes* in ready-to-eat foods that do not support its growth rather than zero-tolerance policies (<100 colony-forming units per gram during the shelf life). Similarly, food control activities within this legislative framework also need to be informed by an assessment of risk. For example, the risk posed by a certain food business or business sector needs to be evaluated based on the nature of food handling and production, the risks posed to public health, and the history of compliance of the business or business sector. This allows for an FCP that focuses its limited resources on the parts of the food chain where risks to public health are greatest. This should lead to better protection of public health rather than a system that attempts to eliminate all hazards at all times, an impossible and arguably futile task.

For an effective FCP, the risk assessment and risk management functions must be involved in good risk communication. For example, the food control legislation should not only be based on risk assessments that are published and which have been communicated effectively but also developed under a transparent system of engagement with all stakeholders. Similarly, food control activities on the ground must take risk into account. For example, enforcement requirements, such as food recall, need to be based on an assessment of the risk and complimented by a risk communication approach that enables food businesses to understand the basis for enforcement action as well as protecting public health by communication to the public.

Finally, an effective FCP, based on the elements of risk analysis, has to be focused on an understanding of the whole food chain because this reflects the exposure pathway that modulates the transfer of a hazard to the consumer and hence modulates risk. An effective FCP is holistic in this respect and should ensure coordination of the different state bodies involved in food control activities at different parts of the food chain. Ideally, the activities of national FCPs should be collated and published in an accessible format, for example, national control programs published under the requirements of European Union food law. This facilitates transparency, but importantly, it acts as the focus for an evaluation of the effectiveness of the control program, which will now be further elaborated.

Purpose of FCP Evaluation

The success of any FCP relies on a thorough evaluation process. This process should measure outputs from the FCP and the results achieved, and establish whether the system, activities, and/or processes as defined are fit for purpose and deliver satisfactory results. In other words, the evaluation process confirms whether the system is effective and that the planned arrangements have been realized (see Figure 1). The effectiveness or 'efficacy' of an FCP differs from its 'efficiency,' although they are somewhat linked. Efficacy looks at whether the outputs of the program lead to the desired outcomes, whereas efficiency considers the relationship between inputs and outputs (see Figure 2).

Other factors that may also need to be taken into account when evaluating an FCP include:

- Relevance – The rationale for adopting policies, strategies, etc. in response to the health needs and other important factors.
- Adequacy – The strategies and policies suitable or capable of meeting consumer needs and requirements.
- Necessity – Is it a legal obligation?
- Progress – The comparison of actual with scheduled activities to ensure that operations are proceeding as planned and scheduled.
- Impact – The overall effect on health and related socioeconomic development.

Measuring Output and Outcomes in Food Safety Programs

The efficacy of an FCP is characterized by two elements; its outputs and its outcomes. Examples of outputs would include the numbers of inspections, numbers of samples tested, or numbers of incidents managed by the control agencies. Examples of outcomes would include reduction in foodborne disease, reduction in complaints, improvements in compliance levels, or reduction in the contamination of the food tested.

Evaluation of efficacy can be achieved by a number of approaches, alone or in combination. Evaluation methodologies rely on verification techniques in order to qualify the selected information and hence inform evaluation conclusions. The main techniques used are:

- auditing,
- monitoring and surveillance,
- review of data and information, and
- peer review.

Irrespective of the technique employed, it is essential that the purpose and objectives of the evaluation process are specified and clearly defined and that the methodology employed is carried out in a structured way. Figure 3 provides a logic sequence for the performance of evaluations and which employs a systematic approach for consistency and thoroughness.

Key factors that need consideration in order to optimize the success of the evaluation itself are the selection of appropriately skilled and competent evaluators as well as the gathering and checking of information to inform the assessment.

It is essential that assessors are suitably qualified and that the appropriate level and type of expertise is available to the evaluation team. Professional judgments form a significant part of the evaluation process and/or in reviewing their results

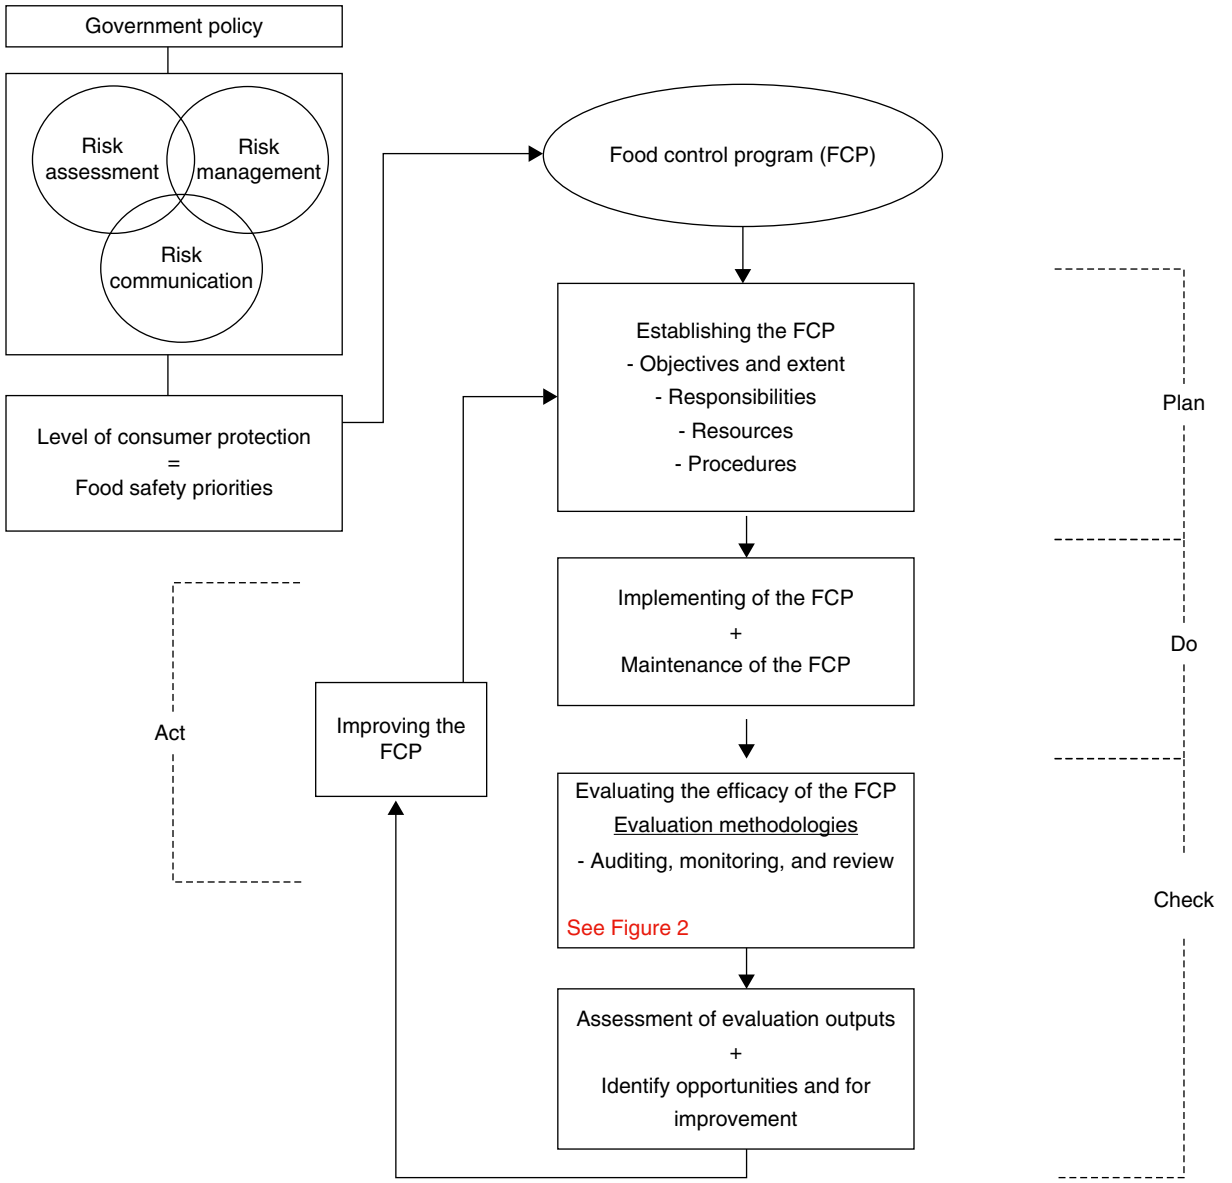

Figure 1 Evaluating the efficacy of FCPs. Reproduced from International Standards Organisation – Guidelines for Quality and/or Environmental Management System Auditing (I.S. EN ISO 19011:2002). Geneva: ISO, with permission from National Standards Authority of Ireland.

and it is essential that these responsible tasks are performed to high standard and are overseen by competent team leaders.

Equally of importance to the success of the evaluation process is the gathering of quality information about the performance of the FCP. Consequently, it is essential that as part of the evaluation process, the information collected is checked and verified for its accuracy and reliability before it is accepted as objective evidence.

Auditing

As an evaluation tool, audits can provide objective assessment of the efficacy of the FCP. Audits of the FCP can provide an evaluation of performance of the system as a whole and/or of the individual processes, elements, or activities. Unlike other evaluation techniques, audits allow an assessment of the design of the system as well as its implementation. Other evaluation techniques tend to focus directly on the outputs of the FCP and their results.

The audit process by nature is a probing technique and has the capability to be tailored to provide targeted evaluations. The audit process is flexible enough to allow horizontal assessment across several common, different interdependent elements or vertical appraisal focusing entirely on one aspect in its entirety.

As a process, audits can be performed by internal assessors as a part of ongoing internal verification that the system and procedures are working efficiently and effectively or they can be carried out exclusively by external auditors. For example, this may be necessary for certification of the FCP to a recognized standard, for example, to ISO 9001:2008. Additionally, external examination may be carried out for regulatory assessment of

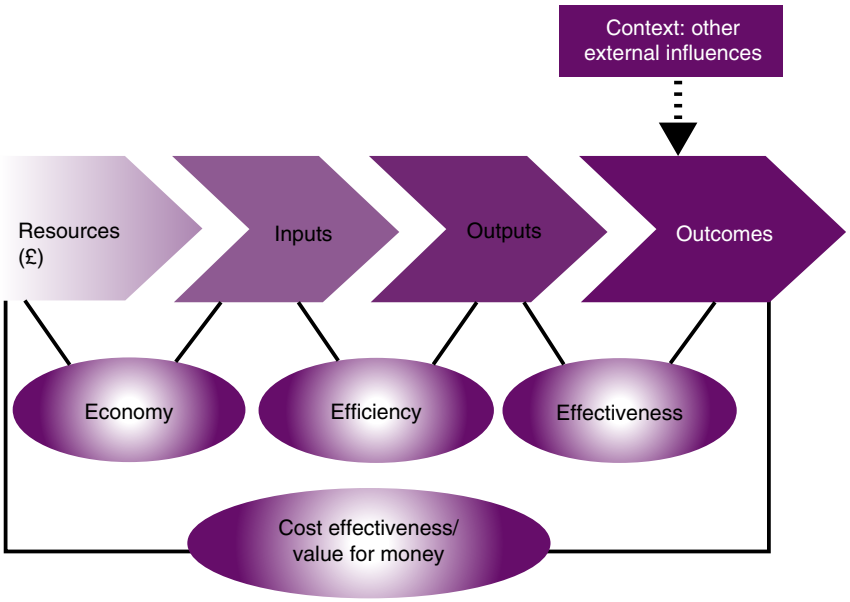

Figure 2 Performance information: inputs, outputs, and outcomes. Reproduced with permission from *Choosing the Right Fabric*, HM Treasury, Cabinet Office, National Audit Office, Audit Commission, Office for National Statistics. http://archive.treasury.gov.uk/performance_info/fabric.pdf

compliance of official controls in various countries. For example, missions conducted by the audit section of the EC's Food and Veterinary Office assess the efficacy of FCPs in both European member states and/or Third Countries.

Consequently, audits can provide a wide range of information as to the performance and efficacy of FCPs. For example, they can provide information as to whether:

- the system as designed is capable of achieving its specified objectives,
- the system is being implemented effectively and that planned arrangements are being carried out as intended,
- the system is being properly maintained,
- the degree of conformity attained by the FCP as judged against specified and predefined criteria, for example, compliance with statutory, regulatory, and contractual requirements,
- the system is meeting the needs of interested parties and is delivering a high level of food safety,
- there is a good level of coordination and cooperation within the FCP and interdependent stakeholders,
- the entire food chain is adequately controlled and covered and that there are no gaps or overlaps, and
- the enforcement activity, action, or method is adequate, appropriate, and consistent.

Monitoring and Surveillance

Monitoring as an evaluation technique tends to focus on the performance of the system, as implemented, and its results. The EC has established a definition of monitoring in European food law:

> Monitoring means conducting a planned sequence of observations or measurements with a view to obtaining an overview of the state of compliance with feed or food law, animal health and animal welfare rules.

Incorporation of monitoring into every aspect of FCPs contributes to the establishment of effective evidence-based public health programs. Monitoring is used to assess if FCP objectives are being achieved and if specific control activities are having the desired impact.

Performance indicators are used to monitor performance of programs and as a basis for a review of effectiveness. According to the World Health Organization (WHO), the ideal indicator should be:

- readily determined (data can be obtained without undue difficulty),
- valid (they should actually measure what they are supposed to measure),
- objective (the answer should be the same if measured by different people in similar circumstances),
- sensitive (to changes in the situation), and
- specific (they should reflect changes only in the situation concerned).

Thorough and systematic consultation with a full range of stakeholders, such as consumers, industry, government policy makers, legislators, and international organizations, will provide useful information about which indicators are most meaningful and how indicators can contribute to a more effective program. By way of general examples, the Pan American Health Organization with the objective of examining the overall performance and status of a food safety program developed the following indicators:

- Foodborne illness – number and incidence of suspected and confirmed cases, by month. Later, cases will be categorized into acute and chronic as well as microbiological and chemical.
- Laboratory analysis – number carried out by each primary food safety organization and findings (e.g., proportion unsatisfactory or proportion positive). As far as possible, reasons should be given for unsatisfactory findings.
- Inspections – number of inspections and compliance rate (by type of establishment).
- Consumer complaints – number of complaints reported, number of complaints found to be justified (by commodity).
- Health education – for consumers, the number of 'programs' conducted (slide shows, TV/radio, newsletters, etc.). For food handlers, the number of course conducted and the number of people trained.
- Exports/imports – annual number of export consignments rejected by commodity and volume (weight). For imports, the quarterly number of rejections by commodity, volume (weight), reason, and source country.
- Legal enforcement – number of notices issued, number of notices complied with, number of prosecutions initiated, number of convictions, number of seizures (by commodity and volume), number of destructions (by commodity), and number of establishments closed.

Monitoring can be complemented by surveillance, which in the context of FCPs, tends to focus on detailed studies of zoonotic disease in animals and humans as well as chemical and microbiological contamination of the food supply. WHO has defined surveillance as:

> the continuous monitoring of the food supply to ensure that the consumers are not exposed to the components in foods, such as chemical contaminants or biological hazards, which pose a risk to health.

In essence, surveillance is an extension of monitoring where the intention is that the information collected is utilized for the purpose of applying active control measures. Effective surveillance requires the timely collection, analysis, interpretation, and feedback in order to take appropriate action; for example, coordinated multiagency surveillance systems will identify unusual strains of pathogens in humans and link these to food and animal isolates. Surveillance systems should be simple and sustainable, tailored to country needs, and maintained and expanded when already in place, while being coordinated at international level through common protocols, analytical tools, and databases.

Review of Data and Other Information

The reviewing and interpretation of data and information is essential to any evaluation of an FCP. Collection and collation of relevant data underpins strategy development, with stakeholders reaching consensus on objectives, priorities, policies, roles of different ministries/agencies, industry responsibilities, and timeframe for implementation. In particular, major problems associated with the control and prevention of foodborne diseases are identified so that effective strategies for the resolution of these problems can be implemented. Analysis of data is a process of inspecting, cleaning, transforming, and modeling data with the aim of retrieving useful information so as to inform decision making and arrive at conclusions. Ongoing analysis of official control data is an integral part of the management of food control programs. A well-coordinated national FCP should ensure the integration of systems to allow for the establishment of links between contaminants and zoonoses in animals and food to foodborne disease in humans. Investment in the development of national reference laboratories is essential for the detailed study of microbiological and chemical contaminants and the development of methods of analysis.

Access to reliable and current intelligence on the incidence of foodborne illness is also critical. It is, therefore essential, that effective linkages are established between food control agencies and the public health system, including epidemiologists and public health doctors. In this way, information on foodborne diseases may be linked with food monitoring data and lead to appropriate risk-based food control policies. This information includes annual incidence trends, identification of susceptible population groups, identification of hazardous foods, identification and tracking the causes of foodborne diseases, and the development of early warning systems for outbreaks and food contamination.

Peer Review

The peer review process is another form of evaluation that can be employed by countries (or organizations) as an additional means of benchmarking their activities and improving performance.

Peer review can be described as the systematic examination and assessment of the performance of a state or organization (the reviewee) by another state or organization (the reviewer), with the ultimate goal of helping the reviewee improve its policy making, adopt best practices, and comply with established standards and principles. An established system of benchmarking is currently operating within the network of European Medicines Agencies and could serve as a model for the food safety sector. At European level, the Food Law Enforcement Practitioners working group have also considered that the peer review/benchmarking approach could also provide a useful methodology in evaluating the performance of FCPs.

Peer review is conducted on a non-adversarial basis, and it relies heavily on mutual trust among the parties involved in the review, as well as their shared confidence in the process. It can provide information on the performance of the FCP as well as the quality of evaluations. Additionally, this technique can be used as part of the capacity building process for developing countries or as a refining tool/process in the pursuit of best practice and excellence for those countries where the FCP is well established.

All verification methodologies have the potential to provide objective assessment of system performance as well as identification of opportunities for improvement. Consequently, a useful outcome of the evaluation process is the identification of weaknesses, which once corrected can improve the efficacy of the FCP.

Assessment of Evaluation Outcomes and FCP Improvement

An equally important stage in identifying and improving the performance of FCPs is the assessment of the outcomes of the evaluation process and a review of their results. Experienced assessors are again critical for the interpretation of evaluation results and in deciding on appropriate recommendations and the necessary corrective and/or preventative actions that should be taken.

In making decisions about FCP, it is essential that reviewers also take into account possible uncertainties in the evaluation process. For example:

- Audits in general take a sample of activities to obtain the overview of the FCP activity or of the system; consequently, they do not necessarily look at every component or element but take a 'snapshot' of compliance.
- Monitoring may indicate varying levels or degrees of performance; however, without on-site verification, this may be incomplete.

Indeed a range of evaluation techniques may need to be employed in unison or in tandem in order to provide accurate oversight and in order to inform appropriate corrective actions. At their most idealistic evaluation, strategies have the potential to correct poor design and highlight inadequate or unsatisfactory performance and lead to appropriate corrective action.

Examples of corrective actions could include:

- reallocation or redeployment of resources due to risk priorities,
- the changing or introduction of a high level FCP strategic objective to deal more effectively in protecting vulnerable groups, and
- adjustment of surveillance programs to cater for new pathogens, chemical contaminants, etc.

Conclusion

Evaluations of the FCP can be used to obtain objective evidence that the system is fit for purpose, is delivering the planned arrangements, and it is achieving predefined goals and strategies.

The quality of the evaluation process and its review is of critical importance. If incorrectly performed, it can misinform and lead to unsuitable strategies and incorrect readjustments of the FCP – in effect, it can do more harm than good.

Arguably, no one evaluation tool is often sufficient in order to gauge effectiveness due to their singularly narrow field of vision; however, collectively, they can bring the true merits and performance of the system into sharper focus and allow objective assessments to be made.

PUBLIC HEALTH MEASURES

Surveillance of Foodborne Diseases

RV Tauxe and JM Besser, Centers for Disease Control and Prevention, Atlanta, GA, USA

Glossary

Active surveillance Public health surveillance that regularly reaches out to diagnostic laboratories or to clinicians to actively collect reports of specific diagnoses of infection.

Cluster of disease A group of cases of a single illness that are suspected to have a common source, because they are caused by the same strain of a pathogen, or have other features in common.

Food vehicle of transmission The specific food to which an outbreak of foodborne illness is attributed by an investigation. That food may be either simple, in which case the investigation narrows it to a single ingredient that was presumed to be contaminated (for example the undercooked eggs used in an omelette), or complex, in which case the investigation is not able to determine the specific ingredient that was a source of contamination (e.g., a fruit salad)

Outbreak of disease A group of at least two cases of a single illness that are demonstrated by epidemiological investigation to have a single common exposure or source.

Passive surveillance Public health surveillance that collects reports of specific diagnoses from clinicians or diagnostic laboratories, which they are required or requested to submit because of notifiable diseases regulations.

Serosurveillance Using a systematic serological survey of a population to determine the frequency of a specific infection in that population.

Surveillance (public health) The systematic collection, analysis, and interpretation of data on specific diseases in a defined population, to guide public health decisions.

Introduction to Public Health Surveillance

Public health surveillance is the systematic collection, analysis, and interpretation of data on specific diseases in a defined population, to guide public health decisions. For infectious diseases, the data come largely from the diagnoses made in the clinical health care system, sometimes strengthened by further study of the microbes themselves. Surveillance can define the magnitude of a health problem, driving policies that will prevent it. Surveillance can identify an increase in the number of reported cases above the expected baseline which may be an outbreak, triggering an investigation so that the source can be identified and controlled. Surveillance also can provide a platform for more detailed studies to improve management and prevention. Finally, surveillance can track trends over time, measuring the impact of control and prevention efforts (see Figure 1).

Surveillance data are usually expressed as the number of cases of a disease occurring in a defined population over a defined period of time. For acute infections, the incidence is expressed as the number of new cases occurring in a population, typically the number per 100 000 in a year. For chronic conditions, the prevalence is usually reported, which is the number of cases that exist in the population at a particular point in time.

The history of foodborne disease surveillance began with the reporting of a few severe clinical illnesses and localized events that were identified as problems with a social gathering, or within an individual county or city. As surveillance grew to cover larger populations, and as microbiological diagnoses became common, more widespread outbreaks became apparent. With standardized molecular subtyping, highly dispersed outbreaks are routinely detected. Surveillance is linked to both the health care systems that produce the diagnostic data, and to the public health systems that refine, analyze and act on it to control or prevent future cases of illnesses.

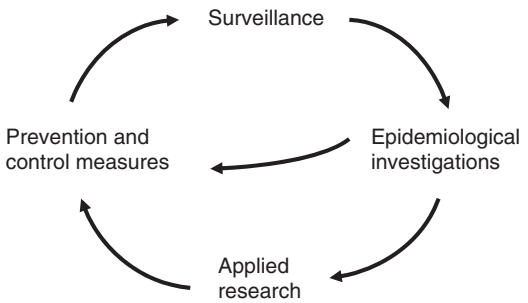

Figure 1 The cycle of public health prevention depends on surveillance to identify problems, investigations to find what went wrong, applied research to devise solutions, control and prevention interventions, and then surveillance to confirm whether the interventions are successful.

Most surveillance is passive, which means that clinical offices and laboratories are requested to report specific diagnoses to public health authorities when they make them. This depends on their remembering which conditions are reportable, how to report them, and on committing the resources to do so. Surveillance can be active, in which case the public health authorities regularly contact laboratories or healthcare providers to ask if there have been any recent cases. Active surveillance is more labor intensive, but also gives more complete and detailed information. Reporting can be mandatory or voluntary. Automated electronic laboratory reporting could make much surveillance reporting instantaneous.

Surveillance can gather information from the entire population, or from a representative group of sentinel sites. Sentinel site approaches make it possible to collect more detailed information at a fraction of the cost of gathering that information from the entire population. For estimating the burden, conducting studies and tracking trends, the sentinel approach may be very useful if the sites represent the entire population. Similarly, surveillance done to track incidence and burden, can take the form of periodic surveys, rather than continuous data collection. However, as outbreaks can occur anywhere and at anytime and can be localized or dispersed, surveillance to detect them needs to cover the entire population continuously.

Surveillance typically gathers basic information about the disease that was diagnosed, the date it began, the date of the first clinical visit, whether illness led to hospitalization or death, the demographic characteristics of ill person, such as their age, gender, occupation and location of residence, and history of recent travel. For some rare and serious infections (e.g., in the US, for botulism, vibrioses, and listeriosis), additional information about severity, treatment and possible exposures is gathered routinely. In addition, the use of molecular subtyping strategies for outbreak detection (see The Power of Standardized Molecular Subtyping in Surveillance) means it is important to supplement this information with characteristics of the bacteria, virus, or parasite that caused the infection, as determined in public health laboratories. This means that clinical laboratories must send the infecting strains they isolate or clinical specimens to the public health laboratories for characterization.

The public health and medical community in each jurisdiction and country decide what conditions should be made notifiable, and how they should be reported. In the US, this authority rests with each state, and the Council of State and Territorial Epidemiologists (CSTE) determines what conditions shall be reported at the national level. The decision to add a foodborne infection to the list of notifiable diseases often follows a large outbreak. For example, in 1988 the state of Washington was the first in the US to make *E. coli* O157 infection notifiable after a large outbreak was traced to ground beef. In 1993, a large multistate outbreak of these infections was first detected in Washington State, and was also linked to ground beef. Following this outbreak, many states made the disease notifiable, and CSTE added it to the list of nationally notifiable diseases.

In Belgium, the medical association operates a sentinel physician surveillance system of great flexibility and efficiency. Each year the association itself chooses which condition are of interest, and a voluntary panel of primary care physicians then supplies information about those diagnoses for the following year. Trends over time are followed by collecting data on a given condition every five years. The system is now being prepared for convertion to electronic reporting.

Most surveillance depends on some level of voluntary effort, whether it be to send a strain of *Salmonella* to the specialized laboratory of serotyping and subtyping, or to fill out a form to report a clinical diagnosis. The more that the participants in that process see some value to doing it, the more successful the surveillance system will be. This value can be enhanced by providing regular summary reports to all participants, and found in the actual use of the information, at local, provincial and national levels to detect and investigate outbreaks, to inform prevention decisions, and to judge their success.

Surveillance is most successful when the information is useful to those who collect it, as well as to the regional and national authorities to whom it is reported. Local authorities may respond to individual reports of illness, use surveillance to plan for local education and prevention efforts, as well as investigating local outbreaks. Regional and national authorities may detect more widespread outbreaks, track trends, and use the information to guide policy at a broader level.

Public health laboratories can add value to the reporting process by providing information feed back to providers in a medically useful timeframe. Typically this means confirming the primary laboratories' results or reporting additional information which the provider finds useful or interesting, such as serotype, susceptibility profile, or toxin type. In some countries the public health laboratory functions as the primary diagnostic laboratory, and has a direct role primary patient as well as surveillance reporting. In other countries the Public Health Laboratory serves a primary diagnostic function only for rare diseases of public health importance, such as botulism, diphtheria, measles, or plague. In either circumstance, the Public Health Laboratory needs to provide the same level of timely reporting that hospital and clinical laboratories provide.

Surveillance systems can be systematically evaluated with several performance measures, including timeliness, completeness, cost, and efficiency. However, it is difficult to justify the cost of even an efficient surveillance system year after year, if no decisions are taken as a result.

Routine Foodborne Disease Surveillance can Gather a Variety of Kinds of Information

Surveillance of foodborne disease caused by infectious and toxigenic microorganisms can be based on collecting different kinds of information, and thus can answer several different questions. This surveillance is the focus of the remainder of this article.

Individual Cases of Diagnosed Illnesses

Case-based foodborne disease surveillance relies on reports from clinicians or clinical laboratories directly to the health department. The specific conditions that are reported are

diagnosed by laboratory identification of a microbial agent, such as salmonellosis, shiga toxin-producing *E. coli* disease (STEC), or listeriosis, or are readily recognizable by distinctive clinical signs and symptoms, such as hemolytic uremic syndrome or botulism.

For some pathogens, this is increasingly supplemented by standardized subtyping of strains to detect widespread outbreaks (See The Power of Standardized Molecular Subtyping in Surveillance). For example, since 1996, multi-state outbreaks of *E. coli* O157:H7 have been identified through PulseNet, the US national foodborne disease molecular subtyping network, using a database at Centers for Disease Control and Prevention (CDC) in which all 50 US states, the United States Food and Drug Administration (FDA) and the United States Department of Agriculture (USDA) participate. Pathogens submitted for subtyping may be further characterized to ascertain changes in antimicrobial susceptibility, or virulence or antigenic profiles.

Disease Clusters and Complaints

The most common type of foodborne disease surveillance worldwide is direct reporting to health authorities of disease clusters by the public or healthcare providers. This might be a report of illnesses from a group dining event, or reports by physicians of unusual numbers of cases with a particular presentation, such as bloody diarrhea. These reports are typically made soon after the event occurred, and although a specific diagnosis is still lacking, an investigation can begin immediately, by interviewing some of the ill persons about their common exposure. Unlike surveillance that depends upon a specific pathogen subtype to link cases, clusters of disease detected in this manner are not dependent on specific agent identification, and thus can lead to the identification of new agents. For example, shiga toxin-producing *E. coli* O157:H7 was first identified as an important pathogen after a cluster of distinctive bloody diarrheal illnesses was reported by an astute clinician.

Cluster reports are most effective at detecting highly localized events, where contamination occurs close to the point of preparation, often in a single kitchen. However, more widespread events can also be detected if they are of sufficient magnitude. The 1993 Milwaukee waterborne outbreak of cryptosporidiosis which affected over 450 000 people was detected after large numbers of cases of unidentified gastroenteritis were reported to health authorities. Investigation of local clusters sometimes provides the key to explaining a more diffuse increase in a particular infection, if they can be linked by microbiological subtyping. As local event-based clusters can be reported and investigated swiftly, they have been critical for solving many large outbreaks, such as the 2008 outbreak of *Salmonella typhimurium* infections associated with peanut products, 2010 nationwide outbreak of *Salmonella enteritidis* infections associated with shell eggs in the US, and an outbreak of *Salmonella typhimurium* DT104 infections linked to imported beef carpaccio in Denmark.

Some jurisdictions gather complaints from the public about individual, sporadic cases of illness that they believe are foodborne. Though this sometimes provides useful adjunct information in an outbreak, the lack of specific agent information and confusion about the actual incubation period limit the value of this source of data for primary outbreak detection.

Summaries of Investigated Outbreaks

In addition to reporting individual cases of illness, some regional and national authorities collect standard reports of outbreak investigations. Routine reporting of investigated foodborne, waterborne or other outbreaks can track conditions for which no other standard surveillance exists such as illness caused by *Staphylococcus aureus* or *Clostridium perfringens* toxins, can help attribute the burden of a broad range of specific agents to specific food groups, and can follow trends in outbreaks related to specific pathogens or foods. These reports also provide an index of public health activity, as the jurisdiction that does not report any foodborne outbreaks is likely to have an inert food safety program, rather than extremely safe food. Codifying the variety of implicated foods and ingredients is a challenge. Capture of the methods used to diagnose the condition, and to implicate the source is important. A simple outbreak reporting system can be a useful and low cost way to begin foodborne disease surveillance in many countries.

Detailed Data Collected from Representative Sentinel Sites

For burden estimation and tracking, it can be more efficient and accurate to collect detailed data from a representative sample of sites, than from the entire population. In sentinel site systems, a group of local agencies are supported to capture case reports from defined populations, to interview the patients, and/or to characterize the pathogens more completely. The measured incidence can be combined across sites, expressed as the number of specific infections per 100 000 population, tracking infections for which reliable surveillance data are not otherwise available. Sentinel site systems have been used in the US to track the viral hepatitides in the Sentinel Counties surveillance system for acute viral hepatitis, to monitor *Pneumococcus* strains circulating in the era of multivalent vaccination in the active bacterial core sentinel sites, and to track 9 infections or conditions often transmitted through food in the FoodNet system. The ten sentinel sites in FoodNet encompass 15% of the US population. This system provides the information with which to estimate the burden of illness, conducts special studies of risk factors, and tracks trends over time. These systems can provide useful information for national decision making, with central funding from the national health authorities. The CDC program FoodNet is also supported by the food regulatory agencies USDA/Food Safety and Inspection Service and FDA.

Surveillance for antimicrobial resistance can be conducted by testing a representative sample of strains. This form of surveillance can identify the emergence of important resistance patterns, such as the general increase in fluoroquinolone resistance in *Campylobacter*, the spread of new multi-resistant strains of *Salmonella* in animal and human populations, or the appearance of highly resistant *Salmonella typhi* in travelers from other countries. As some of the resistance in bacteria that

cause human foodborne infections arises in animal populations as a result of the use of antimicrobial agents in agriculture, similar monitoring of strains detected in animals and in foods can track the flow of strains between specific animal reservoirs and humans. Using the same assays and breakpoints simplifies comparison of resistance between these groups. Linking resistance information to other clinical and epidemiological information about the cases can clarify the clinical impact of resistance, its association with foreign travel, and the role of exposure to specific foods. Selecting strains using a standard sampling frame, such as 1 of every 20 *Salmonella* strains submitted for serotyping, can limit the expense while providing a valid measure for the whole population. In the US, the tri-agency collaborative National Antimicrobial Resistance Monitoring System measures resistance to a standard panel of antimicrobial agents in *Salmonella*, *Campylobacter* and other pathogens, isolated from ill people, from meat and poultry, and from animals. In Denmark, the Danish Integrated Antimicrobial Resistance Monitoring and Research Program provides detailed resistance tracking.

Monitoring Strains from Animals and Food

Some foodborne surveillance systems encompass monitoring the food supply, and even the food animals, to identify problems early. For example, the Danish Zoonosis Center has long integrated information from all three sources into one system. In the US, the PulseNet system includes laboratories from USDA and FDA, and veterinary and meat isolates are gathered in a parallel VetNet system that uses the same method, permitting cross checking.

Foods are tested for the presence of microbes throughout the food supply as part of verification of process control, and as part of purchase contract conditions. Although such testing is beyond the scope of this article, it could provide useful warning signals to public health if reported in real time. On rare occasions, the identification of a pathogen in a specific food can reveal an ongoing outbreak, and may rapidly suggest the outbreak source, when if can be shown that the ill persons in the outbreak indeed ate that food. In 2009, the FDA began collecting mandatory reports of isolates of pathogen from ready-to-eat foods that it regulates. This 'Reportable Foods Registry' may open a new window into contamination of many foods. Systematic random sampling of foods has been used to identify the frequency of contamination, useful for risk analysis and modeling, and to track specific problems such as antimicrobial resistance.

Serosurveillance

Measuring the frequency of antibodies to specific pathogens has long been used in viral disease epidemiology, and is also being used now to measure the true incidence of other infections. For toxoplasmosis, serological studies of the population show that 11% of the US population is infected. Recent exploratory work in Denmark and the Netherlands for *Salmonella* and *Campylobacter* indicates that these infections are far more frequent that had been previously estimated. Many of these immunizing infections may be asymptomatic, so they would not be detected by surveillance that depends on clinical illness. Such estimates may simplify comparison of infection rates among countries.

Non-Specific Clinical Syndrome Events

Surveillance can be based on health indicators that are less specific than a specific microbial diagnosis. These indicators may be based on broad clinical syndromes, such as the number of visits to emergency departments for acute gastroenteritis, the number of stool specimens submitted for culture to clinical laboratories, or the number of calls to poison control centers (Henning, 2004). They can also be more general markers of illness, such as sales of antidiarrheal medications, rates of school absenteeism, or even the number of internet browser searches about diarrheal illness. Such methods have been useful in establishing the scope and size of an outbreak once it is detected, but though in theory they might signal problems with food or water earlier than other systems, but in practice have not yet usefully detected a foodborne outbreak before other standard means of surveillance. The nonspecific nature of the tracked indicators makes for an unfavorable signal-to-noise ratio, which requires that the outbreak need to be large to stand out from background illnesses. Furthermore, the potential disease clusters that are identified still need to be followed up by traditional investigation methods, further reducing potential time advantages.

Monitoring Consumer and Health Care Provider Behaviors

Periodic surveys can gather information at the consumer level on the frequency of diarrheal illness, health care seeking, of dining in restaurants, or taking an international trip, or of risky behaviors such as eating raw shell eggs, raw shellfish, or raw ground meat. Such surveys are typically done by telephone, depend on the cooperation of the survey subjects, and can provide useful information for risk assessment and to improve consumer education.

One can also survey health care providers and microbiologists about their behaviors. Physicians and nurses can describe their usual practice given a patient with gastroenteritis, though response rates are typically low. Surveys of microbiologists can track changes in diagnostic procedures, types of transport media, enrichment or culture media used, and non-culture based 'dip-stick' diagnostics they use, that may have an impact on laboratory based surveillance.

General Limitations of Surveillance

All Surveillance is Incomplete

All surveillance systems capture a fraction of the total number of illness cases that occur, so reported cases, reported outbreaks, complaints, nonspecific health indicators, or other surveillance data represent the tip of the iceberg of illnesses. That fraction is small when a surveillance system begins, and increases as more participants start reporting, so a new surveillance system matures over several years. This fraction is the result of sampling, partial utilization of healthcare or healthcare products, underdiagnosis of illnesses, and of

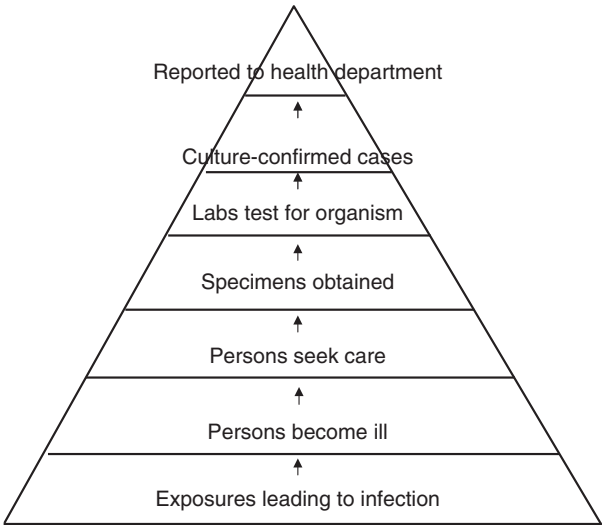

Figure 2 The pyramid of under-recognition and under-reporting in public health surveillance. The sequence of events from the sick individual to the final report to public health loses events at each step.

underreporting. To be reported as a case for surveillance based on diagnosed illness, a cascade of events must occur, which can be visualized as the 'surveillance pyramid' (See **Figure 2**). The ill person must first seek medical attention, then have a diagnostic study such as a stool culture. The diagnostic study must yield a positive result, and that result must be reported to the health authorities. The cumulative probability of these steps, from the bottom to the top of the pyramid, is the multiplier, which estimates the number of cases that actually occur for each one that is reported. For example, it was estimated using data from around the year 2000 that in the US there were 38 cases of human salmonellosis for every one that is reported. The multiplier for a given disease can vary over time. The same multiplier was estimated to be 29.3 using more recent data from around 2007. In addition to underdiagnosis, many cases may be diagnosed, but not reported. Thus, in 1995 passive voluntary case reporting of *Campylobacter* infections in the US yielded an incidence of 2.5 per 100 000 population, whereas active surveillance in FoodNet showed the actual rate for 1996–98 was 21 diagnosed infections per 100 000. In general, it is more important to understand the multiplier than to try to change it, as efforts to 'improve' a stable surveillance system by increasing the fraction of cases diagnosed can introduce artifacts that make interpretation of results more difficult. Surveillance of disease clusters (such as group events) and complaints similarly are likely to capture only a fraction of disease that might be reported by these mechanisms.

Case-Based Surveillance Depends on what can be Diagnosed Routinely

Surveillance collects reports of diagnosed clinical conditions, so conditions that are not routinely diagnosed are not trackable by this mechanism. Neither norovirus nor *Clostridium perfringens* intoxication are systematically diagnosed in clinical practice, and as a result, case-based notification does not occur for these conditions. Before 1979, though they likely were common, *Campylobacter* infection were rarely diagnosed. After new diagnostic assays were introduced routine clinical use, surveillance could begin to capture these infections. More recently, the routine diagnosis of *E. coli* O157 and other shiga toxin producing *E. coli* has made surveillance for those infections possible. The increasing use of nonculture based rapid screening tests that do not yield a microbe that can be subtyped now threatens surveillance based on molecular subtyping, unless definitive microbiological diagnosis is also pursued.

Surveillance Varies Greatly by Country

As each surveillance system is wedded to a particular health care delivery system, the results of surveillance can vary among nations because of differences in their health care systems. This complicates the comparison of those results. For example in the late 1990s, the reported annual incidence of *Campylobacter* infection was reported to be 21 per 100 000 in the US and five times higher, 110/100 000 in England. However the estimated reporting multiplier to account for underdiagnosis was 38 for the US, suggesting the estimated actual incidence 798/100 000 in the US, whereas the multiplier was only 8 for England, suggesting the estimated actual incidence there was 870/100 000, very similar to that of the US at the time. This shows how differences in the frequency of health care seeking and of obtaining cultures can greatly change the reported incidence. If in one country, health care is freely available, and microbiological diagnosis of a broad range of pathogens is routine, and in a second, the patient may often pay for a consultation, and for diagnostic microbiology, whereas in a third it is restricted to hospitalized illnesses, and to a limited range of pathogens, the results of surveillance should vary substantially. One would expect the reported rate of infections to be much higher in the first country, lower in the second and even lower in the third. That means that systematic measurement of the frequency of those key steps in health care seeking and testing is needed to make such comparisons. Reporting requirements may also vary from one state or province to another within a single country, further complicating interstate or international comparison.

Advanced surveillance can provide the detailed data needed to determine which differences are real. For example, in the US, FoodNet sentinel surveillance revealed substantial geographic variation in the annual incidence of campylobacter infections, from 7 per 100 000 at the lowest site to 34 per 100 000 at the highest. These differences were not explained by data from surveys of laboratory practices, health care seeking behavior or risk factors; they may indicate real but unexplained differences in frequency of poultry contamination with *Campylobacter*.

Surveillance Costs Money, and More Detailed Surveillance Costs More

Surveillance is rarely of direct value to the patient themselves, but rather benefits society in general. Therefore, the cost of surveillance is usually borne by the public sector, often

separated from the cost of clinical diagnosis. Even in countries with full coverage of healthcare costs, the surveillance information is assembled by a specialized group, and the laboratory subtyping is done in a specialized laboratory, both of which are separate from the clinical diagnostic staff. The true value of surveillance lies in the better decisions around prevention it leads to, and it is difficult to justify the cost of conducting surveillance year after year, when no decisions are taken on the findings.

Case-Based Surveillance is Usually Slow

Once symptoms occur, the cascade of events in the surveillance pyramid takes time, so that the report to the health department may occur several weeks later. It is thus not unusual for the initial public health interview of a case-patient to take place three or more weeks after the person was exposed to whatever it was that made them sick. Depending on human memory for details of food exposures at such a remove can be challenging. Outbreaks associated with fresh produce may be over before they are solved, which restricts our ability to directly prevent continuing transmission, although the feedback provided to industry and regulatory agencies helps in long-term prevention efforts. The time frames for testing and reporting can be accelerated, by using faster shipping and testing protocols, though this is also likely to be more expensive. Laboratory-based surveillance is too slow for botulism, which requires immediate and rapid action to ensure the risk is controlled. For this reason, botulism surveillance in the US and other countries depends on reporting the clinical suspicion of a likely case, supported by the provision of antitoxin at no cost by public health authorities. Despite these limitations, pathogen-based surveillance remains the single most effective tool for detecting and resolving widely spread, low-level events, such as outbreaks commonly associated with contamination of mass distributed food items.

Not All Outbreaks are Caused by a Single Strain of Pathogen

Outbreaks are usually presumed to be an increase in one specific type of infection, a presumption that is reinforced by the use of surveillance case definitions and subtyping methods that add specificity. It is well to remember however, that contamination is not always with a single organism. Outbreaks occur that are caused by more than one strain of a pathogen, or even by more than one pathogen. Identification of a second pathogen in the food vehicle that caused the outbreak can sometimes uncover a second unsuspected cluster of infections from the same source. Focusing on the dominant strain leads to efficient identification of the problem, but when many strains are characterized within a single outbreak it is not unusual to find some variant strains, and even sometimes other pathogens. When this occurs in a waterborne outbreak, the presumption is that the water was contaminated with sewage containing multiple kinds of pathogens. When it is recognized in foodborne outbreaks, it may indicate a similar sort of contamination has occurred.

Using Surveillance for Public Health Decision Making

Detecting and Investigating Outbreaks

The investigation of foodborne outbreaks is a key driver for pushing food safety. An increase in reports of a particular illness, or of infections with one subtype of a pathogen, above the background noise of expected cases is the signal that something has gone wrong, and that an epidemiological investigation is needed to determine whether there is a correctable food safety gap. Once a cluster of possibly related cases is detected, and an investigation begins, ongoing surveillance continues to be critical to the investigation, identifying new cases, defining the scope and dynamics of the outbreak, and showing when it is over. Detecting an outbreak is at its heart a signal-to-noise problem, and the nature of the outbreaks detected thus depends on the sensitivity of the surveillance system itself. If hundreds of cases of a severe illness occur over three days in one city, even the most informal and primitive surveillance will suffice, whereas the same number of cases distributed over two months across an entire country is likely to be missed, without sophisticated surveillance based on pathogen subtyping. Without such subtyping, the dispersed outbreaks will be invisible against the background of sporadic unrelated cases. Subtype-based surveillance can also be used to assess risk of an apparent cluster. If a group of illnesses thought to have some connection are shown to have a variety of unrelated subtypes, the likelihood that the cluster represents a common source is reduced.

Measuring Trends in Incidence

Ongoing surveillance can document changes in the incidence of an infection over many months or years (**Figure 3**). An increase can herald a new problem, and detailed analysis of trends may reveal that changes are prominent in certain age or ethnic groups, providing more clues about the drivers for the change. Once a major control measure is put in place, surveillance to track a decrease in incidence of the target pathogen is a key outcome measure. Programs that reduce the frequency of pathogens in food may be assessed by the frequency of contamination in food samples, but the ultimate measure is a decline in the incidence of disease. For this reason, in 1996 in the US, when a major pathogen reduction effort was about to be introduced for the American meat supply, the FoodNet active surveillance program was set up to provide an important measure of success. National incidence targets were set for several key infections, and reaching the goal for STEC *E. coli* O157 in 2009, was a major milestone for judging the overall success of the prevention program.

Estimating the Burden of Illness

Estimates of the overall burden a pathogen places on the health of the public can help decision makers focus prevention on the greatest threats. Surveillance provides the foundation for estimates of the burden of diseases. By multiplying the incidence of reported cases by the frequency of underreporting and under-diagnosis, the true number of illnesses can be estimated. This can be done for individual

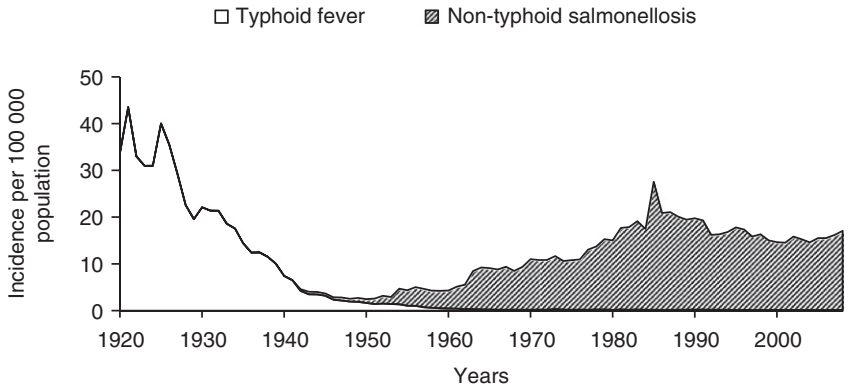

Figure 3 The fall and rise of the reported annual incidence of salmonellosis in the United States, 1920–2008. The first part of the 20th century is dominated by infections with *Salmonella typhi*, controlled by water and sewage treatment, and milk pasteurization. The second part is dominated by non-typhoid salmonellosis.

infections under notifiable disease surveillance, for the conditions that are only tracked as the result of outbreak reporting, and even by extension for illnesses of undetermined etiology. The burden can be expressed in terms of illnesses, hospitalizations, or deaths based directly on surveillance data, or in terms of the number of days of missed work or school, of days in hospitalization, or as the loss of years of life due to death or disability.

Attributing Foodborne Infections to Specific Foods or Commodities

Estimating the fraction of the burden of illness that specific foods are responsible for can help focus decisions based on risk, so that control measures are targeted at the highest risk foods. This attribution is not a simple calculation, and can be done in a variety of ways. It is complicated because food itself is complex, with many different food types and ingredients, and preparation methods. It is also complicated because the attribution may be considered at several points in the food chain, from the point of consumption, the point of processing or the ultimate reservoir. Most public health data provides information at the point of consumption. For a few infections routine case surveillance can provide this attribution. For example, home-canned vegetables cause most cases of botulism, and eating raw shellfish causes most *Vibrio* infections. For other infections, such as those caused by *Campylobacter* or *Salmonella enteritidis*, for which several important food vehicles have been identified, a case-control study of reported sporadic cases, that compares the reported exposures of diagnosed cases with those of healthy controls can provide useful information about the point of consumption attribution. In Denmark, the distribution of bacterial subtypes of *Salmonella* found in human infections is compared with that of *Salmonella* found in food or food animals has been used to estimate the fraction of salmonellosis due to different animal reservoirs. A similar approach may in the future be possible with multilocus sequence typing for *Campylobacter*. The most generally applicable strategy for attributing foodborne illness to food commodity groups is based on outbreaks reported to foodborne outbreak surveillance. Using simple attribution, which counts outbreaks linked to specific individual foods, the Health Protection Agency of England and Wales follows trends in outbreaks attributable to specific commodities. Attribution based on analyzing food identified in outbreaks by their component ingredients, or so-called complex attribution shows promise.

Managing Risk with Quantitative Risk Assessment

Quantitative risk assessment (QRA) depends on information from many sources, including public health surveillance. Where the final output of QRA models is human illness, surveillance data are often used to calibrate the entire model. For many risk assessments, surveillance data and attribution derived from them are the basis of the model. For example, a QRA that preceded new regulations enacted for eggs in the US was based on surveillance, case-control studies and information gathered during outbreak investigations. An extensive QRA of *Campylobacter* in the Netherlands used surveillance data and other information to provide attribution estimates).

The Power of Standardized Molecular Subtyping in Surveillance

Since the mid 20th century, pathogen-based case reporting has played an important role in food safety. *Salmonella* serotype-based surveillance was one of the first and most successful of such programs. Serotype-based attribution studies in Denmark allowed the development of targeted interventions that resulted in marked reductions of *Salmonella* contamination in pork, chicken, and eggs. Serotype surveillance led to the control of baby turtle-associated salmonellosis in the US during the 1970s, and the development of *Salmonella enteritidis* control programs in egg production. One of the largest outbreaks detected through routine serotype surveillance was the 1995 outbreak of *Salmonella enteritidis* associated with ice cream contaminated by raw eggs. This outbreak was responsible for an estimated 250 000 widely dispersed cases throughout the US over a several month period. The capacity of nations to conduct serotype-based foodborne disease surveillance varies greatly. Differences between nations are primarily due to the strength of the underlying surveillance

infrastructures, which in turn are owing to differences in funding, training, availability of reagents, priorities, and even cultural traditions. The World Health Organization Global Foodborne Infections Network (GFN; formerly Global Salm-Serv) seeks to improve the capacity of countries to conduct surveillance for foodborne and enteric infections by identifying and minimizing these limitations through interdisciplinary partnerships (WHO, 2010).

Molecular-based pathogen-specific surveillance has brought the power of pathogen-based surveillance to a new level in those areas of the world that have fully implemented it. In the US, PulseNet, the national and international molecular subtyping network for foodborne disease surveillance, has become one of the most sensitive tools available for detection of unrecognized problems in our food safety systems related to microbial contamination. This type of surveillance, like serotype-based surveillance, uses the underlying presumption that individuals sharing a common exposure are more likely to share a genetically matching microbe than unrelated individuals. By using a refined case definition which separates likely related from likely unrelated cases, the signal-to-noise ratio is improved, which in turn reduces the number of cases required to detect outbreaks and make meaningful associations. Using molecular subtype data as part of routine surveillance resulted in dramatic increases in recognized outbreaks of *E. coli* O157:H7 and *Salmonella typhimurium*. PulseNet has been responsible for detection of most of the high-profile foodborne disease outbreaks due to *Salmonella* species and *E. coli* O157:H7 in the US during the 2000s, resulting in the recall of hundreds of millions of pounds of contaminated products and remediation of underlying problems in multiple industries.

Local outbreaks thus identified may also be linked together to identify broader trends, such as the 1998 international shigellosis outbreak due to contaminated parsley the 2008 outbreak of *Salmonella typhimurium* infections associated with peanut products, 2010 nationwide outbreak of *Salmonella enteritidis* infections associated with shell eggs in the US. In the latter two examples involving relatively common agents and exposures, local events linked by pulsed-field gel electrophoresis (PFGE) triggered trace-back investigations, adding critical specificity to the investigations.

Standardized molecular subtype-based surveillance has become our most effective mechanism for detection of low-level widespread contamination events. Detection of these 'new scenario' outbreaks has become increasingly important as our food supplies have become centralized, and food is routinely shipped to all corners of the globe. PulseNet, and other similar surveillance programs, depend on strict standardization in laboratory methodology to make possible laboratory-to-laboratory and country-to-country strain comparisons. Rapid development in the field of molecular biology has yielded many technologies competing with PFGE, such as multi-locus variable number tandem repeat analysis, multi-locus sequence typing and subtyping systems based on single nucleotide polymorphisms. New subtyping technologies may offer significant advantages over PFGE such as greater strain discrimination, ability to evaluate strain similarity in a meaningful manner, reduced labor cost, and higher throughput. However, it can be argued that standardization with a single global method has been far more important than the particular method chosen. Because food production and food contamination have truly become a global issue, effective surveillance requires a global testing standard.

Standardization of epidemiological data and methods has the potential for increasing the effectiveness if foodborne disease outbreak detection and investigation for the same reasons that standardization has proved useful for laboratory data. Case interview forms are generally not standardized within countries or even local jurisdictions, making region-to-region or country-to-country comparisons of exposure or demographic data difficult to impossible. To a large degree these differences are necessary, as regional foods and food preparation practices are an important part of our rich global cuisine. Nevertheless, global trade has significantly increased the amount of globally common food exposures, and at each smaller jurisdictional level commonalities would be expected to increase. Standardization of common data elements is a promising new frontier of foodborne disease epidemiology. The Listeriosis Initiative and OutbreakNet projects in the US seek to address this problem by building common data elements among participants. The Council to Improve Foodborne Outbreak Response (CIFOR) has created guidelines in an effort to stimulate global adoption of common best practices (Cifor, 2009).

Finally, integration of food monitoring and animal disease monitoring data with human disease data (described above) has the potential for making all three data streams more valuable. PFGE pattern matches between case isolates and food or animal isolates are used for hypothesis generation in case cluster investigations, and the presence or absence of human disease cases matching regulatory sampling isolates helps food regulatory agencies assess risk.

The Future of Surveillance

More Rapid Diagnosis and Subtyping

Determination of subtype is a critical part of much surveillance. Faster methods for subtyping can speed up the detection of clusters. For example, molecular serotyping of *Salmonella* can be completed in one day, whereas traditional methods take three. A faster protocol for PFGE in PulseNet decreased the time required to one day rather than three. Express shipping of organisms from clinical to public health laboratories can speed up surveillance.

In the near future, a more profound change is likely for some foodborne pathogens. The move toward culture-independent diagnostic testing in clinical laboratories is likely to make surveillance more difficult, and interfere with disease tracking, burden estimation and outbreak detection and investigation. New rapid diagnostic testing technology based on lateral flow (immunochromatographic) strip and enzyme-linked immunosorbent assays can make testing faster, and more available in parts of the world where bacteriological culture is impractical. However, these methods do not yield a bacterial isolate, which means they undercut the isolate-based surveillance programs such as PulseNet. As clinical laboratory practice moves away from traditional bacteriology, it is critically important for public health to develop new subtyping

assays and platforms that do not depend on culture-derived isolates, and to integrate them with the new clinical laboratory practice. The same challenge faces regulatory agencies that depend on the isolation of an organism to take some legal actions.

Faster and More Standardized Interviews of Reported Cases

The patient interview is the other critical element of routine public health surveillance. A detailed interview with the patient provides vital exposure information that can be used to identify the food vehicle in the outbreak setting. It depends on human memory, which places a premium on conducting the interview soon after the illness begins, even before an association with other cases is identified. The initial interview is the best time to collect a detailed food history for the relevant time period preceding the illness, but finding the person and conducting that detailed interview takes time. Many jurisdictions conduct a rapid screening interview lasting no more than 5 min, and then later conduct a more detailed interview when the person's illness is found to be part of an outbreak. This means more subjects forget what they ate. A dedicated case interview team may overcome the obstacles, and obtain detailed information rapidly. As more diffuse outbreaks straddling jurisdictions are detected, it becomes more important to standardize the elements of this interview across jurisdictions, so that the information can be compared and combined rapidly

In future such information may be gathered more efficiently via the internet. An interview could be triggered on diagnosis, and might be integrated into the health care system itself. For infections often transmitted by foods, an initial screening questionnaire collected by self-report could include a standard list of foods and other exposures, as well as an opportunity to schedule a more detailed person-to-person interview.

New Pathogens will Emerge

Unpredictably but reliably new pathogens will continue to emerge around the globe as microbes evolve, changing trade and traffic transfer new foods and pathogens, and changing food production opens up new niches. Conditions that were once unrelated to food may be foodborne after all, like Chagas' disease in Brazil now transmitted by contaminated açai fruit juice. Nipah virus encephalitis in Bangladesh is transmitted from fruit bats to humans via contaminated sugar palm juice. Surveillance systems will need to change constantly to keep up. In the US, infections with the non-O157 shiga toxin producing *E. coli* are now being recognized with at least the same frequency as those due to O157, and surveillance methods need to adapt to capture them. Detailed microbiological investigation of well-investigated outbreaks of foodborne illness of undetermined etiology is a particularly efficient way to identify new or unrecognized foodborne agents. Such outbreak investigations may lead to new pathogen discovery, with methods such as DNAse sequence-independent primer amplification, high density arrays, or metagenomic methods.

The Distinction Between Sporadic Cases and Outbreaks will Diminish

Sporadic cases may often not be truly sporadic single cases, but may be part of far-flung unrecognized clusters. In the modern world, both people and foodstuffs can travel far, and as a result people affected in a single outbreak can fall ill in many different neighborhoods, counties or states. The old highly focal outbreak affecting persons attending one school or one local gathering still occur, but many outbreaks spread across multiple jurisdictions. These dispersed outbreaks are recognized by surveillance that matches up individual strains, and investigated with collaborative teams. Many dispersed low intensity outbreaks may be occurring all the time, generating the background noise of surveillance that we recognize as the status quo.

Collaborative Global Networks will Reveal Global Outbreaks

Growing global collaboration in surveillance networks and investigation is likely to reveal more truly global outbreaks. In a review of foodborne outbreaks associated with international trade over a 7-year period on three continents, two outbreaks among 30 reviewed were identified that affected at least two continents at once. Both were outbreaks causing *Salmonella* infections in Europe and Australia. One was traced to contaminated sesame seed halvah from the Middle East, and the other to dried peanuts from China. For both, detection was aided by *Salmonella* serotyping, which is a universal typing system that has fostered the detection of many outbreaks and is used globally. Use of more standard surveillance and investigative techniques around the world is a critical part of preparing the global surveillance of the future. The collaborative training network called WHO Global Foodborne Infection Network fosters successful basic methods of foodborne disease diagnosis, surveillance, outbreak investigation, and estimates of the burden of illness. Begun in 2000, this program has trained persons in nearly all countries from public health, agricultural and food safety agencies. The global molecular subtyping consortium PulseNet International has trained public health microbiologists in 70 countries, using 7 regional coordinating centers. While still in development, PulseNet International has already played a critical role in detection or investigation of several multi-country outbreaks, such as an outbreak of *Salmonella senftenberg* infections associated with prepacked basil, shigellosis outbreaks associated with catered airline meals and raw baby corn. As more countries build robust programs for surveillance and investigation of foodborne disease and join global subtyping networks, we should expect to find and investigate many more global foodborne outbreaks, which will identify more unsuspected food safety hazards, and lead to progress in reducing the global burden of foodborne diseases.

PUBLIC HEALTH MEASURES

Foodborne Disease Outbreak Investigation

J Rocourt, Paris, France

Glossary

Carrier An individual (or animal) who harbors a pathogen but does not exhibit clinical symptoms of disease and may be a source of infection.

Case An infected person having specific clinical, laboratory, and epidemiologic characteristics.

Cluster A cluster is a small group of cases of one disease that may be linked by time and geography. In the context of foodborne disease, after an investigation of a cluster, cases may be linked by a common food or food premise and may be described as an outbreak.

Common- or point source outbreakAn outbreak of disease in which susceptible individuals are exposed simultaneously to one source of infection. Foodborne disease outbreaks are most often point source outbreaks. The epidemic curve for this type of outbreak is characterized by a sharp rise in the number of cases that slowly decrease. Most illness appears within one incubation period.

Continual source outbreak An extended outbreak of disease or illness that occurs when a source remains contaminated and individuals continue to be exposed to this source. The epidemic curve for this type of outbreak is characterized by ongoing peaks overtime (e.g., weeks and months).

Epidemiological evidence The demonstration of an association between a food and human illness through an increase in the number of cases in a population, place, or timeframe with exposure to the same food product; or a statistically significant association between illness and food consumption.

Foodborne outbreak Refers to two or more cases resulting from ingestion of a common food (epidemic is often reserved for crises or situations involving larger numbers of cases over a wide geographical area).

Propagated source or person-to-person outbreak An outbreak of disease that spreads from one person to another via the fecal–oral route. The epidemic curve for this type of outbreak is characterized by a relatively slow, progressive rise. The curve will continue for the duration of several incubation periods of the disease.

Sporadic case A case that cannot be linked epidemiologically to other cases of the same illness.

Foodborne Outbreaks

A foodborne illness (or disease) is any illness of an infectious or toxic nature caused or thought to be caused by eating or drinking a contaminated food or beverage. A foodborne illness outbreak is defined as: (1) an occurrence of two or more cases of a foodborne illness linked to a common source or event, resulting from the natural, accidental, intentional, or malicious contamination of foods by microbiological, chemical, inert physical hazards, and other similar substances; or (2) an unexplained, unexpected increase in the number of a similar illness, and food is a likely source. However, a single case for certain foodborne illnesses such as botulism or chemical poisoning, justifies an in-depth investigation.

The size and scope of a foodborne outbreak can greatly vary according to the pathogen or toxin involved, the volume of food which is contaminated, the step of the food chain where contamination occurs, where the food is consumed, and the number of people who eat it. Briefly, there are two major types of foodborne outbreaks:

- *A common source outbreak*: A small, acute, and highly local outbreak, which happens when several people get sick after eating, for example, at a classic church dinner, wedding reception, or other social event. The outbreak is immediately apparent to those in the local group who promptly contact medical and public health authorities. Attack rates are high and food contamination, with high levels, occurs just before consumption because of a terminal food-handling error in a kitchen.
- *A community exposure outbreak*: Regional, national, or international diffuse outbreak caused by a commercially distributed food product, as a result of increasingly centralized production and wide distribution of large volumes of a great diversity of raw and processed products moving across boundaries (people are ill with similar symptoms, a pathogenic microorganism is involved, but there is no known exposure that links these people together). Attack rates are low and surveillance data must be rapidly compared over increasingly broad regions to detect cases as the increase in cases may be inapparent against the illness background. Food vehicles are contaminated early in the

production process or distribution chain, with low levels of pathogens. Such outbreaks require a large investigation team to clarify the extent of the outbreak, identify a specific food, and determine the source of contamination. Controlling and preventing such outbreaks can have industry-wide implications.

The objectives and the overall structure of investigation are the same for both types of outbreaks.

The scope of this document is intended to provide a short overview of the investigations of foodborne outbreaks, which go through several steps that are described here in a certain order, but in reality investigations are dynamic and several steps may happen at the same time.

Stages in an Outbreak Investigation

The primary reason of the investigations is to protect public health by mitigating or containing the effects of a foodborne illness outbreak in a timely and effective manner, which means: (1) reducing to the minimum the number of primary cases of illness, (2) reducing to the minimum the number of secondary cases of infection, by identifying cases and taking appropriate action to prevent any subsequent spread, and (3) preventing further episodes of illness by identifying continuing hazards and eliminating or minimizing the risk they pose.

These investigations include identifying the etiologic agent, people at risk, the mode of transmission and vehicle, the source of contamination and contributing factors, determining the potential for ongoing transmission, implementing specific interventions or corrective actions that will stop the outbreak, fulfilling statutory obligations and responding to public and political concern, and evaluating existing recommendations or strategies for preventing similar outbreaks in the future.

Keys for Successful Investigations

A Multiagency, Multidisciplinary Team

There are three major components in foodborne disease outbreak investigations:

- epidemiologic investigation to characterize the disease, determine the etiology of the outbreak, identify risk factors for disease, and implicate foods and/or food handlers as transmission vehicles through descriptive and analytical studies;
- environmental assessment to determine routes of contamination and contributing factors and recommend appropriate control; and
- laboratory analysis to provide definitive etiologic diagnosis by testing human and environmental specimens.

All these steps will frequently identify applied epidemiologic and food safety research.

A proper foodborne outbreak investigation cannot be conducted without these components, which are often performed simultaneously. The different steps that include identifying and investigating an outbreak, conducting traceback and source investigations, developing and implementing control measures, and taking steps to prevent recurrence require the efforts of a team of individuals with different areas of expertise, such as epidemiology, sanitation, food control and safety, clinical medicine, clinical and food microbiology and chemistry, public health, law enforcement (in case of intentional contamination of food), risk management, and communication. This means that no single agency has the expertise, resources, or authority to complete an investigation from beginning to end; public health and food agencies in charge of foodborne illnesses must, therefore, operate together in good partnership, sometimes on several administrative levels depending on the nature of the outbreak. The identification of key stakeholders is crucial and depends on the size and scope of the outbreak (number of cases and population at risk, causative agent and severity of the disease, the location and extent of the outbreak, public concern, media impact, potential public health problem, etc.).

Communication

- *Communication within the team*: Successful investigation of an outbreak depends on the close communication, coordination, and collaboration in a consistent and timely way within the multidisciplinary team. Roles and responsibilities of each investigator and his corresponding agency should be very early and clearly defined. A comprehensive system of communication among investigators – epidemiology, environmental health, and public health laboratory – and their respective agencies is critical in ensuring concurrent activities do not interfere with each other and guide the activities of individual investigators, in controlling outbreaks and preventing additional illnesses. Especially regarding community exposure outbreaks, it is important that information is communicated to other involved agencies when the outbreak is detected and investigation is ongoing rather than waiting until it has been completed.
- *Public communication*: Ensuring that communication activities reflect general risk communication principles as well as emergency and crisis communication practices are a crucial aspect of successful outbreak management. This means early, regular, and accurate communication by experienced personnel who share relevant information with at least:
  - health, food, water, agricultural, and veterinary authorities to ensure accurate case finding and facilitate the implementation of control measures;
  - the media who are a major interface between the general public and health authorities and can play a role in outbreak investigation and control; and
  - the general public and those at greater risk (regular press releases via newspapers, radio, television, Internet, etc.): information on implicated food products and how they should be handled and advice on hygiene measures to reduce the risk of spread.

Surveillance

Beside the well-known means of detection of 'traditional' outbreaks – i.e., associated with a local event – such as

notification by citizens, clinicians, laboratories, review of passive surveillance, etc., the development and enhancement of current surveillance systems of foodborne disease play a major role in detecting clusters of cases spanning large geographical areas in terms of time, place, or patient characteristics and the linkage of seemingly unrelated cases. Early detection will maximize control and prevention efforts. Among the various surveillance methods, laboratory reporting and disease notification contribute importantly to outbreak detection (in spite of underreporting of cases and long delays in notification). Disease notification is the collection of reports of cases of illness required by law, which include information on symptoms, on demographic characteristics, and key risk factors. Laboratory-based surveillance relies on the collection of information about microorganisms that have been previously identified by laboratory testing of ill persons. The systematic and timely analysis of data can provide useful information for detecting outbreaks, particularly when cases are geographically scattered or clinical symptoms are nonspecific. Detecting widespread outbreaks is also facilitated by early typing of isolates, which may detect a surge of a particular subtype and link apparently unrelated infections. This has been frequently demonstrated by PulseNet, which is a US network of local, state, and national public health and regulatory agency laboratories that use pulsed-field gel electrophoresis (PFGE) with standardized protocols for subtyping of case isolates to rapidly identify groups of isolates that have the same PFGE pattern, which may indicate that the cases have a common origin. In addition to epidemiologic and laboratory surveillance, monitoring of food products by conducting facility inspections, sampling foods, and analysis of consumer complaints helps in identifying food processing deviations.

Standardized Documents

Planning and preparation activities are essential and investigations should be organized in a standardized approach that is critical in saving time and resources and responding in an effective manner to foodborne alerts. Any implicated agency should develop a procedure manual that includes a number of standardized documents such as guidelines, procedures, questionnaires, forms, etc., which can be adapted with minimal efforts to each outbreak hypothesis: list of staff to constitute the outbreak investigation team with their responsibilities/tasks; list of contacts who may become involved; outbreak investigation flowchart; notifiable disease form; case definition; questionnaire for epidemiologic investigation; clinical and food microbiological protocols for sampling, swabbing, labeling, storage, transport, detection, and identification of foodborne pathogens; checklist for food inspectors; general and pathogen-specific food vehicle-specific questionnaires; templates for sharing information with other agencies; communication protocols for health-care professionals, consumers, media and industry; final report, etc. This enables investigators to become proficient and ensures that pertinent information is collected; staff should be trained in the use of these items. All information received and decisions taken by the investigation team should be recorded reliably and with the appropriate level of confidentiality, and special attention should be paid to the chain of custody, the validity of sampling procedures, as well as the handling of samples being increasingly under scrutiny in legal cases. The means by which these procedures are carried out may vary depending on number and experience of staff, resources, type of outbreak (common source outbreak vs. community exposure outbreak), etc.

Epidemiologic Investigation

The main objectives of an outbreak investigation are to (The Centers for Disease Control and Prevention (CDC; Atlanta, GA, USA) developed a computer software program called Epi Info™, which can be used to prepare questionnaires and analyze data. (The software is free, a copy of which can be obtained via the Internet.)

1. collect information related to the outbreak to identify cause and the source of an outbreak;
2. limit the exposure of consumers;
3. implement corrective measures, such as recall of products, information to consumers, and diagnosis and treatment of affected persons; and
4. develop conclusions and recommendations for control and prevention of further outbreaks.

Establishing the Existence of an Outbreak

Foodborne disease outbreaks may be identified from various sources, such as complaints from private citizens, medical examination of ill individuals at hospitals, clinics or physician offices, regular surveillance of reportable foodborne disease by epidemiologists, laboratory-based pathogen-specific surveillance, laboratory subtyping surveillance, information received through the media and public information officers, reports from food safety regulators and environmental health specialists, etc.

Most reports of foodborne illness are sporadic and are often not associated with a recognized outbreak. To determine if there is an outbreak, the current number of new cases is compared with incidence data of the same disease over a similar time period. If the number is unusually large or unexpected for the given place and time, an outbreak may be occurring (it must be made sure that a rise in numbers is not due to changes in reporting procedures, case definition, diagnostic methods, increased awareness, etc.).

Following detection or reporting of a suspected outbreak, further information is collected to confirm and describe the outbreak. Confirmation of the existence of an outbreak requires verifying that the diagnosis is correct and common to all cases. Detailed information should be collected as soon as possible – basic demographic information, 3-day food history, symptoms, hospitalization, treatment and test(s) ordered and/or results, large gatherings attended (e.g., common meals, social events, information on any contacts, including those who also are ill, etc.).

The preliminary information collected during the initial report may help determine if an investigation is necessary or not, may also provide important clues about the cause and source of the outbreak and help guide the direction of the investigation.

Defining Cases and Conducting Case Finding

As the outbreaks and their corresponding investigations can quickly become complex, it is important to establish a clear understanding of the outbreak as early as possible. Organizing the preliminary information will help in the development of a case definition and may also provide clues about the pathogen, its transmission, and source.

After verifying the diagnosis by (1) obtaining appropriate clinical histories by interviewing ill persons, family members, and/or physicians to record all relevant symptoms, possible exposures, and other details that might reveal the disease in question and (2) performing laboratory analysis (patient and/or environmental samples) to confirm the etiologic agent, a case definition is developed. It is a standard set of criteria to be used in the outbreak investigation to decide who is a case and who is not and includes information about simple and objective clinical criteria, pathogen or toxin if known, laboratory results, and essential elements of person, place, time, etc. The initial case definition may be refined as new information becomes available during the course of the investigation. Separate definitions may be developed for confirmed, probable, and suspected cases.

Using the case definition and a standardized questionnaire (demographic information, occupation, date of onset and symptoms, laboratory results, medical treatment, list of foods recently consumed, travel history etc.), investigators search for additional cases related to the outbreak by reviewing surveillance reports, requesting local clinical and laboratory professionals to notify cases of the particular illness more quickly, reviewing emergency room records or nursing homes for similar illnesses, obtaining lists of attendees from social events/functions, asking health officials in surrounding areas for illnesses that might be related, and alerting the public directly through the media if needed. This allows a more accurate estimate of the magnitude of the outbreak, reduces the likelihood of bias that may occur by focusing on cases detected early, and increases the sample size (and consequently the statistical power to identify risk factors).

At this point, the investigator is searching for common associations based on time, place, and person. Two major tools are used to arrange all incoming data: an epidemic curve and maps which should be regularly updated.

An epidemic curve is a graph that depicts the association of the time of illness onset of all cases that are associated with the outbreak. Time is plotted on the horizontal axis and the number of cases is plotted on the vertical axis. An epidemic curve provides information about the extent of the outbreak, potential period of exposure, and possible mode of transmission. Its shape may suggest what kind of outbreak is occurring: a common source or point source outbreak, propagated source or person-to-person outbreak, and continual source outbreak.

Maps and pictures are helpful in showing the geographical location or layout of the place in which an outbreak has occurred. The 'spot map' is a pictorial description of the spatial distribution of cases within a specific setting or geographical area. The cluster of cases may indicate a local exposure in the community as restaurant, place of employment, school attended, or in contrast a wide geographical area in case of continual source outbreak, for example. This spatial information may be crucial to the outbreak investigation and may provide clues about the source of the agent and/or nature of exposure.

At the end of this preliminary phase, a careful decision will be needed about whether or not to continue the investigation; it may be apparent at this stage that there is no further public health risk or in contrast that further action is needed.

Developing Explanatory Hypothesis about Likely Sources

Using the information previously gathered, the next step is to consider which specific exposure(s) may be the source of the disease and develop a hypothesis (or several hypotheses) to guide the direction of the investigation and initiate appropriate control measures. A useful hypothesis is testable, sensible, and fits the full picture of what is known about the cause of the outbreak and factors that may have contributed to illness.

Analysis of data collected from the interviews with patients (symptoms, incubation and recovery periods, and food items consumed), laboratory (characteristics of pathogens), and inspection of the premises provide insights into the source and cause of illness. Formulating hypothesis about the likely source of the outbreak should begin early in an outbreak investigation to narrow the focus of the investigation (by preparing a short list of suspected food and drinks) and uses time and resources most effectively. It should be an iterative process in which possible explanations are continually refined or refuted as more information becomes available. The sooner those hypotheses are developed, the sooner public health interventions and appropriate control measures may be instituted.

Achieving a hypothesis is often difficult and may take more time for outbreaks distributed over very large geographic areas; the delay inherent in surveillance systems contributes to the time needed to recognize clusters; as a consequence, food history interviews of cases, which are highly dependent on their memories, may be imprecise and this is especially challenging given the vast variety of existing foods and their ingredients. Investigation of restaurant clusters may be particularly informative in this type of outbreaks.

Developing Epidemiological Studies to Test Hypothesis

The goal is to compare the characteristics of a group of well persons with those of ill persons to quantify the association between specific food exposures and disease under investigation; this is done using a questionnaire that is designed specifically for the common exposure. This type of evidence may also be useful to further guide the environmental and/or laboratory investigation. The most commonly used analytical methods during foodborne outbreak investigations are cohort studies and case–control studies. The study design is usually chosen according to the characteristics of the outbreak.

Retrospective cohort studies are feasible for outbreaks in small, well-defined populations in which all exposed and nonexposed persons are identifiable (e.g., a church supper). In this study, the risk of illness is compared by what was eaten and what was not eaten. The outbreaks analyzed using cohort studies are usually small; they require significant resources as all exposed and unexposed individuals are interviewed.

In many circumstances, no clearly defined group of all exposed and nonexposed persons can be identified. In such

situations (primarily when the illness is rare or not easily identified or when it is easier to select participants for the study based on the illness status), case–control studies are used (e.g., when a widely distributed, branded food commodity is implicated in a nationwide outbreak). In this study design, cases and controls (nonill individuals) are compared to determine the likelihood of having eaten specific foods. Ideally, controls should be similar to cases and represent the same population except they do not have the disease.

Using appropriate statistical tests, the investigators determine the strength of the association and whether more than one food might be involved. Additional studies to supplement the epidemiological study might also be conducted at the same time: an environmental study to help determine the source of exposure and mode of transmission; and laboratory studies to confirm that a particular microorganism or chemical agent is present in clinical and/or environmental samples.

Analyzing the Data Collected and Interpreting Results

Analyzing epidemiologic investigation include: (1) reevaluating the case definition and ensuring that persons classified as cases meet the case definition; (2) updating epidemic curves; (3) calculating frequencies and percentages, median, and ranges for the incubation period and recovery period, the attack rate, food-specific attack rates, and relative risk ratios for a cohort study or odds ratios for a case–control study.

This information should then be integrated with the findings obtained during the environmental assessment and laboratory analysis. General knowledge about foodborne illnesses should be collectively used to help explain what happened, what measures should be taken immediately, and what steps should be selected to prevent similar situations from occurring in the future.

For a causal relationship the following criteria should be met: (1) the epidemiologic investigation obtained evidence from most of the people in the study; (2) the time relationship between the consumption of the food item and onset of illness is consistent with the incubation period of the disease under investigation; (3) the probability of the association being due to chance is less than 1% ($p = .01$) if there are several food items being tested, or less than 5% ($p = .05$) if the study began with a hypothesis of an association with a single food item; and (4) no important causes of bias in the conduct of the investigation was detected. Finding no statistical association does not mean that the outbreak was not foodborne but only that the source could not be identified.

Further investigations would likely be required for the following circumstances: outbreak is still ongoing, insufficient information to implement control measures, etiological agent, source and mode of transmission unknown, new or unusual etiological agent, and high public/media interest.

Environmental and Food Assessment

The primary goals of an environmental investigation are: (1) identifying the source, mode, and extent of the food contamination; (2) assessing how the causative agent could have survived; (3) determining whether conditions were conducive for subsequent growth or toxin production by the causative agent; and (4) identifying and implementing corrective interventions. This investigation step may involve one food facility or several. It is conducted in parallel with epidemiological and laboratory investigations.

An early visit to implicated food premise(s) should be made as soon as possible as the amount of physical evidence will diminish with time. The range of information obtained during the investigation will depend on the nature and size of outbreak, the causative agent, the type of establishment involved (catering operations, food manufacturer, health-care facilities, day cares and schools, community functions, etc.), the resources available and local priorities; as much information as possible should be obtained. During investigations of diffuse outbreaks spread over wide geographical areas, traceback extends beyond the immediate preparation of the implicated food to the whole food chain and cooperation at all levels of industry is required.

To prevent future occurrences, the establishment(s) should be regularly revisited after the outbreak to assess how the recommended specific measures are implemented.

Investigation of a Food Establishment

During a foodborne disease outbreak, investigation of a food establishment will often require:

- interviewing food workers (managers and any employees who may have had a role in the processing or preparation of suspected foods);
- collecting information on menus, production schedules, food sources and supplies, water system, processes (cooking, storage, service, possible cross-contamination sites, temperature and processing records (including work schedules)) and on the overall operations and hygiene with details of food safety management systems (such as Hazard Analysis Critical Control Point (HACCP));
- producing a map of the premises, showing its layout and food flows and pathways; factors such as the location and availability of sinks and appropriate hand washing facilities, and determining whether separate areas are maintained for the preparation of raw and ready-to-eat foods may be crucial in the understanding of food contamination;
- reviewing employee sickness records and medical screening of food handlers and staff training.

To save time and resources, the sanitary investigation should be guided by what is already known about the outbreak from epidemiological and laboratory investigations and about known reservoirs for the suspected causative agent.

Investigation of a Suspected Food

When the role of a suspected food is investigated, the purpose of the traceback investigation is to identify high-risk food preparation and handling practices that contributed to transmission of a particular disease in an outbreak. Main steps are the following:

- Preparing suspected product description (list of all raw materials and ingredients used, sources of the ingredients, physical and chemical characteristics including pH and water activity, use of leftover foods in processing, intended

use, product lot numbers, expiration dates and sales records, volume prepared, preparation schedule, etc.).

- Observing process: The food inspector should determine the three hazard categories that pose the greatest potential for foodborne illness:
  - Contamination hazards: Food source (food from unsafe sources, adulterated food, etc.), cross-contamination (raw foods not well separated from ready-to-eat foods, equipment not properly cleaned and sanitized, etc.), poor personal hygiene (lack of hand washing, bare hand contact with ready-to-eat food, ill food workers, etc.), environmental contamination (improper storage, usage of chemicals, presence of insects or rodents, lack of potable water, improper sewage disposal, etc.).
  - Survival hazards: Inadequate cooking, unfit reheating temperatures, etc.
  - Bacterial growth or toxin production hazards: Improper holding, unsafe cooling, or inadequate refrigeration, improper cold/hot holding temperatures, preparation several hours before serving, etc.

When conducting a traceback investigation, additional information should be collected such as label and package information, product name, package code/lot number, expiration/sell by/use by date, date of purchase, etc.

- *Interviewing food handlers*: Food handlers are persons who directly handle or prepare food. They may work as paid employees or volunteers, serving food in a variety of settings. Food handlers have an important responsibility to follow safe food preparation and handling practices to prevent illness. Poor hygiene practices among food workers continue to be a major contributing factor to foodborne illnesses. Analysis of more than 800 foodborne outbreaks demonstrated that the most frequently reported factor associated with the involvement of the infected worker was bare hand contact with the food followed by failure to properly wash hands, inadequate cleaning of processing or preparation equipment or kitchen utensils, cross-contamination of ready-to-eat foods by contaminated raw ingredients, and (for bacterial pathogens) temperature abuse. All food handlers should be carefully interviewed about food practices of the suspected food during the relevant period (exact flow, preparation, handling, unusual circumstances, practices, etc.), recent illnesses and knowledge and training in food safety. Although workers have been implicated in outbreaks, they were not always aware of their infections, either because they were in the prodromic phase before symptoms began or because they were asymptomatic carriers. Specimens for microbial analysis should be obtained from food handlers who are ill. If the same type of pathogen is recovered from specimen of a worker and the suspected food, it is essential to determine whether he or she is a potential source of the problem or is infected because of having eaten the same food. Because of the potential for food handlers to transmit pathogens through the food they serve, work restriction and exclusion requirements have been established for infected food handlers in a number of countries.
- *Taking appropriate measurements*: To understand circumstances of food processing and contamination with a pathogenic agent, some measurements can help such as time and temperature conditions, water activity, and pH.
- *Drawing a flowchart of the operations and conducting an outbreak hazard analysis*: After getting a complete history of the suspected vehicle and its environment, all data collected should be entered on a flowchart to facilitate the assessment of factors that may have contributed to the outbreak. The flowchart should show the flow of the different operations of the suspected food, equipment used, results of measures taken, name of persons performing operations, etc. This allows to conduct a hazard analysis and identify critical control points. If practices at the time of the outbreak can no longer be reconstructed, a flowchart of current practices may be useful.

In case no source of contamination at the place of preparation is identified, the possibility that contamination may have occurred before the food or ingredient arrived at the establishment should be documented. The simultaneous occurrence of multiple outbreaks due to the same pathogen at different places is often evidence of primary contamination by raw foods that may commonly be contaminated.

Managers of the implicated establishment(s) or company/companies will be kept informed of developments by the inspection authority.

Laboratory Analysis

Both epidemiological and food safety investigations usually involve laboratory testing. The purposes are: (1) identifying or confirming the clinical diagnosis through identification of the causative agent (frequently microorganism and more rarely chemical agents) from human samples; (2) ensuring proper identification of the disease; (3) determining if the causative agent is present in the implicated food and/or its environment; and (4) tracing the sources of, and evaluating the extent of, contamination of food that may be associated with the outbreak.

At any stage of the epidemiologic investigation, advice can be provided on potential or likely microorganisms or toxins that may be causing the outbreak, the appropriate specimens to collect, and timeliness of tests that can be used for diagnosis and typing. Laboratory identification of a pathogen can quickly validate a hypothesis and allow easier implementation of control and preventive measures.

One of the most important factors in the identification of etiologic agents responsible for foodborne disease outbreaks is the collection and analysis of clinical specimens as early as possible, at the time of first contact with the patient. Most foodborne infections are diagnosed through the identification of the pathogen in stool (vomitus samples can be used in some cases; blood cultures and serology for systemic infections); other specimens such as swabs from rectum, nostrils, skin, or nasopharynx may be collected from food handlers. Because pathogens or toxins may remain in the intestinal tract for only a short period of time after illness onset, stool specimens should be collected within 48–72 h after onset of symptoms during the period of active diarrhea (and whenever possible from individuals who have not received antibiotic treatment). Once the diagnosis has been confirmed

by laboratory tests, there is usually no special need to obtain additional samples if individuals manifest characteristic symptoms.

The main objective of the food and environmental testing is to support the epidemiologic investigation in detecting the pathogen in the suspected food and understanding how and why the outbreak occurred. The value of laboratory results in food microbiology depends on the quality of the samples submitted. Sampling and laboratory analysis of foods should be oriented by epidemiologic and environmental investigations to avoid wasting time and resources. Suspected foods (raw items, ingredients, leftovers, unopened packages, foods known to be associated with the causative agent, etc.) and environmental samples (work surfaces, equipment, containers, hand-washing facilities, etc.) should be collected early in the investigation as the amount of physical evidence will diminish with time. If an implicated food has not been identified at the time of sampling, a large number of specimens may be collected and stored for subsequent laboratory testing as additional information becomes available.

Molecular methods have contributed substantially to improve foodborne disease outbreak investigation. Polymerase chain reaction technology is increasingly used for the rapid detection and identification of pathogens. Comparison of PFGE patterns of isolates from clinical and food specimens can provide additional evidence to support epidemiologic data; PFGE can also be used to include additional related cases and exclude cases that are epidemiologically unrelated to an outbreak. Genetic sequencing technology is becoming more and more useful for assessing the relatedness of various foodborne pathogens.

Enhanced laboratory testing of clinical, food, and environmental specimens is important to confirm the pathogen of a foodborne disease outbreak, and therefore should always be considered as a high priority. However, confirmed laboratory identification is not needed to start an investigation, and outcomes of an investigation may be based solely on epidemiologic evidence (food with a short shelf life no longer available, leftover foods or foods in open containers may have been contaminated after opening, pathogen difficult to detect because of low number of cells, heterogenous distribution of the pathogen in food, overgrowth by other organisms, no test to detect a new pathogen, etc.).

Control Measures

The priority should be to implement effective control measures to prevent future foodborne cases as early as possible in the course of the investigation based on the initial hypotheses. Control measures and possibly regulatory actions should be considered at any time during the investigation and implemented as soon as new evidence is available. Ideally, control measures should be based on the results of all investigations but this may delay the prevention of further cases. Public health officials may not wait for laboratory proof of contamination, especially during diffuse and widespread outbreaks, and decide on control measures on the basis of strong epidemiologic evidence on the origin, spread, and development of the disease. This practice results in earlier action to protect the public's health. However, before initiating a control measure, it is necessary to consider the effectiveness, timeliness, costs, availability of resources, personnel requirements, and possible secondary consequences of proposed actions. Specific interventions – such as recalling a food product or closing food premises – can have very important economic and legal consequences.

Control measures will depend on the mode of spread and are dictated by the particular circumstances of each outbreak. They can be implemented through three main areas: (1) the outbreak source (e.g., modification of a food production or preparation process, exclusion or restriction of food handlers who are at high risk of spreading illness, closing of food premises, prohibition of the sale or use of certain foods, etc.); (2) the vehicle of transmission (recall/seizure of contaminated product, modified handling, or cooking instructions, etc.); and (3) human transmission (exclusion of cases from school or work, protecting groups at risk, advice on personal hygiene, food safety education of food workers, etc.). Continued monitoring of the control measures is essential to ensure that the measures are effective in the long term.

Preventing reoccurrence of outbreaks requires the implementation of a well functioning and integrated food control system, with collaboration among all the components, including food law and regulations, food control management, inspection services, food monitoring, laboratory services, and education of the consumer.

Deciding the End of the Outbreak, Debriefing, and Final Report

Information collected from the epidemiologic investigation, in combination with the environmental investigation and laboratory testing results, should be regularly reviewed to determine whether the outbreak investigations can cease or whether further investigations are required. Further investigations would likely be necessary if the outbreak is still ongoing, if there is insufficient information to implement control measures, in case of unknown, new, or unusual etiological agent and/or transmission mode, and if there is a high public/media interest.

An outbreak ends when illnesses are declining and the number of new illnesses reported returns to the number usually expected. Surveillance continues even after to make sure the outbreak is over and detect possible new cases associated with an incompletely controlled source or a secondary contamination involving another food or location linked to the first outbreak.

The postoutbreak debriefing/reviews should be organized in a timely manner after the resolution of the outbreak and are useful, especially to consider any lessons that can be learned from the outbreak and its management, and to discuss dissemination of this information to prevent future outbreaks. After analysis of epidemiologic, laboratory, and environmental data, conclusions should be summarized in a report. The report should also include a root cause analysis of the incident, i.e., identifying the underlying factors which have led to the failures causing the incident, for example, weakness in inspection of food establishments, gaps in legislation, or failures in training or education of food handlers.

This report should be written in a scientific publication format, should clearly reflect the complexity of the outbreak, and should improve the quality of future investigations. It includes, at least, a description of the outbreak, data on confirmation of the outbreak source, methods to prevent a reoccurrence, difficulties met in implementing the control measures, assessment of the effectiveness of outbreak control measures, discussion of any legal issues that may have arisen and possible needs for further scientific studies. Data must be protected from public disclosure to the extent allowed by law so that they can be shared with other agencies and it may be wise to seek legal advice about production of final reports in case of potential legal proceedings. The report is distributed to all investigators, to appropriate local and national authorities, and individuals; it should also be provided to the managers of any facility involved in the outbreak for prevention measures and education of food workers. Synopses may also be used for press releases and postings on websites.

Finally, proper reporting of the investigation includes also notification to the national foodborne outbreak surveillance system whose aim is to provide data to improve understanding of the human health impact of foodborne outbreaks and identify the most frequently involved pathogens, foods, settings, and contributing factors.

Conclusion

The careful and meticulous investigation of foodborne and waterborne outbreaks is essential for disease control and prevention. However, too often, outbreaks of foodborne disease go unrecognized or unreported or are not investigated. Analysis by CDC of data on foodborne outbreaks reported in 1998 and 1999, which occurred in the US in FoodNet surveillance areas, indicates that in 71% of these outbreaks, no confirmed etiology was identified, and in 46%, no suspected food vehicle was identified. Main reasons include delay in the outbreak notification, insufficient staff or resources, no specific food hypothesis, too small number of cases for an analytical epidemiologic study, or lack of memory of what has been eaten by people, negative food testing. In resource-limited countries, outbreaks of foodborne disease are poorly investigated, if at all, mainly because appropriate skills and resources are unavailable. Developing web-based alert systems, enhancing current surveillance systems to identify large outbreaks as early as possible, establishing multiagency/multidisciplinary foodborne outbreak investigation teams with role and responsibilities clearly identified, working with specific written protocols/procedures, standardization of investigations methods and of sharing reports, training of investigators by online courses, especially for food traceback, improving communications between agencies are some developments to be considered worldwide.

Most foodborne etiologic agents were discovered in the course of outbreak investigation. An important objective of an outbreak investigation, which is a unique comprehensive source of information, is to identify and resolve unanswered scientific questions about foodborne disease and pathogens; well-conducted investigations may provide significant information on the natural history of the disease, reveal new vehicles, transmission modes, contributing factors, groups at risk or specific risk factors, and improve our understanding of food processing and how the contamination occurred at specific points in the food supply. Field investigations provide unique opportunities to address research issues, such as new detection, diagnosis, and typing/subtyping methods, studies on the behavior, resistance, or elimination of the pathogen in food, the emergence of new antibiotic resistance; case–control study of sporadic cases to identify risk factors evidenced during outbreaks. Data derived from outbreaks can be used for risk assessment, particularly for dose–response and source attribution. New knowledge on food safety may also be gained by monitoring the impact and effectiveness of control measures. Such understanding not only facilitates future investigations but is also essential for developing effective long-term control strategies. By updating regularly our scientific understanding about agent, disease, host, and environment, outbreak investigations play a key role in preventing foodborne disease, demonstrating the need for new public health or regulatory policies and/or broader education efforts – of the public, the food industry, or health-care providers. In addition, outbreak investigations can also provide valuable information to ongoing surveillance activities, may be used to evaluate and improve public health programs, and guide future strategies in these areas; epidemiologic investigations can also contribute to teaching, as an example of the systematic and logical approach an epidemiologist follows in an investigation, and a valuable on-the-job training and experience for future outbreaks.

PUBLIC HEALTH MEASURES

Environmental Assessment in Outbreak Investigations

CA Selman, US Centers for Disease Control and Prevention, Atlanta, GA, USA

Glossary

Contributing factors These are determinants that directly or indirectly cause an outbreak. A contributing factor can be biological, behavioral, or attitudinal; or an element of the physical or social environment; or the result of policies related to the problem. Examples include retort, pasteurization, or cooking temperatures that do not destroy or reduce pathogens, poor personal hygiene of food workers, or cross-contamination. Contributing factors are what happened to cause a foodborne outbreak.

Critical control point (CCP) A step at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Critical limit (CL) A criterion that separates acceptability from unacceptability.

Environmental antecedents These are supporting factors for the contamination, survival, or increase of biological or chemical agents in food. They may be related to people, equipment, food process, food type, economics, or other circumstances. In other words, antecedents are the reason why the contributing factors occur. Antecedents are sometimes referred to as root causes of foodborne outbreaks.

Environmental investigation It is a generic term used to refer to all aspects of the environmental component of an foodborne illness outbreak (FBIO) response. It encompasses the environmental assessment and/or traceback activities.

Foodborne illness outbreak (FBIO) environmental assessment (EA) The systems-based component of an FBIO response that fully describes how the environment contributed to the introduction and/or transmission of agents that cause illness or could cause illness. Environment is everything external to the host, including air, food, water, animals, plants, climate, etc., as well as people and the social and built environments. All aspects of the external environment can be listed as variables that, in relation to transmission, are neutral, conducive, or protective. From this description, contributing factors and environmental antecedents to an outbreak can be determined.

Hazard analysis critical control point (HACCP) plan A document prepared in accordance with the principles of HACCP to ensure control of hazards that are significant for food safety in the segment of the food chain under consideration.

Traceback investigation An investigation activity that is conducted to support the epidemiological investigation in determining the likely food vehicle and/or the location of the food contamination, such as the point of final service, production, food source, etc.

Introduction

For decades, public health and food regulatory agencies have been investigating foodborne illness outbreaks (FBIOs) to identify and understand their etiology. There are three critical components of an outbreak investigation: epidemiological, laboratory, and environmental. The epidemiological and laboratory investigations have typically focused on identifying the pattern of illness, the pathogen, and the food associated with the outbreak. There are accepted epidemiological and laboratory procedures and methods for conducting these components of FBIO investigations. Some organizations have compiled and published the find ings from these investigations. Data from these reports are sometimes used to measure the burden of foodborne dise ase within a population, to characterize the agents involved, and to suggest food safety priorities. The epidemiological and laboratory components of a foodborne outbreak investigation are discussed in more detail elsewhere within this encyclopedia.

Investigations of FBIOs are historically conducted by local and state/provincial public health agencies. FBIO response requires a multidisciplinary approach involving laboratorians, epidemiologists/communicable disease control authorities, and environmental health/food regulatory personnel. This multidisciplinary team's focus is to:

- stop an outbreak quickly if it is ongoing;
- understand what happened to cause the outbreak (i.e., contributing factors);
- implement immediate measures to prevent the ongoing contamination of food;
- understand why the outbreak occurred (i.e., environmental antecedents);
- implement long-term measures to prevent future outbreaks in the establishment; and

 doi:10.1016/B978-0-12-378612-8.00412-1

- use the information from the outbreak investigation to inform public policy on preventing future outbreaks.

The team may include – in addition to epidemiologists, clinical and environmental laboratorians, and environmental public health professionals – microbiologists, food technologists, engineers, hydrologists, geologists, veterinarians, and others, as outbreak circumstances warrant.

Detection of FBIOs is accomplished through laboratory-based surveillance for reportable diseases and through consumer complaint follow-ups. In the USA, more FBIOs are identified through consumer complaints than through laboratory surveillance. In either instance, once an outbreak has been detected, epidemiological investigations with laboratory support are conducted to verify that an outbreak has occurred and to determine the outbreak agent and vehicle. Other investigation activities, such as environmental or traceback investigations or other environmental activities, may follow.

Environmental assessments (root cause analysis) determine the contributing factors and environmental antecedents that led to the outbreak and/or to support the epidemiological investigation as needed. Traceback investigations support the epidemiological investigation when the source of contamination, such as the point of final service, production, etc., has not been determined or when there is a need to assist epidemiologists in determining the likely vehicle. Traceback investigations may follow the vehicle back through the farm-to-fork continuum to determine the source of contamination; when the food vehicle has not been identified; such investigations involve detailed food ingredient menu item reviews at the point of final service.

Other activities, such as regulatory/enforcement actions, can involve recalls, public alerts, and legal actions when indicated. Prevention/research activities may be initiated on the basis of investigation findings to permit a further understanding of the agent, the mode of transmission, and contributing factors, as well as to permit identification of ways to prevent similar outbreaks from occurring in the future. Research addressing data gaps may also be conducted by industry, academia, and government agencies.

FBIO Environmental Investigations

The processes and or methods of all aspects of a foodborne outbreak investigation have evolved over decades. A routine inspection using the current regulations as a guide provided the first approach to FBIO environmental investigations. This often produced a list of violations of the regulations, but often missed the true causes. During the late 1970s and early 1980s, published articles by Dr Frank Bryan and others called for a focus on the factors that caused outbreaks rather than regulation violations during FBIO environmental investigations. In more recent years, hazard analysis critical control point (HACCP) principles, such as identifying hazards, critical limits (CLs), and critical control points (CCPs), are employed in FBIO environmental investigations. The addition of systems theory as an additional tool to understand why outbreaks occur represents the latest step in the evolution of the FBIO environmental investigation process.

Unfortunately, the FBIO environmental investigation is carried out less frequently and with less insight than other activities during an outbreak investigation. In many instances, these investigations are conducted by food safety regulatory agencies that often conduct regulatory inspections in response to outbreaks, rather than making epidemiologically, laboratory data-driven/systems-based environmental assessments to identify both contributing factors and environmental antecedents.

The findings from FBIO environmental investigations are also less frequently compiled and shared. As a result, there is often a lack of data from the environmental component of an investigation. In addition, there are doubts regarding the quality of the data that are reported, as those data relate to actual contributing factors. An example of such findings is the suggestion that improper food holding temperatures are a possible contributing factor for norovirus illness outbreaks. This is an unlikely relationship for an agent that does not reproduce outside a host cell. Improper food holding temperatures are a common violation in food inspection work; yet, such food holding temperatures are not an appropriate contributing factor to report in a viral FBIO.

To identify and understand the environmental causes of FBIOs, an investigator must conduct a systems-based environmental assessment, informed by available epidemiological and laboratory data, seeking to identify both contributing factors and their environmental antecedents. The FBIO environmental assessments will be covered in the remainder of this article. Developing an understanding of FBIO environmental assessments requires a basic understanding of a few general systems theory concepts, and an understanding of the food chain and its corresponding systems.

General Systems Theory

Systems theory is not new. It was first proposed in the 1940s by biologist Ludwig von Bertalanffy. He is recognized as one of the founders of general systems theory. His theory has been applied to a number of fields and served as the source of inspiration for those working to understand and influence complex systems.

Some of the basic concepts Bertalanffy proposed are especially helpful in framing the complexity of food facilities in such a way that food safety managers and foodborne outbreak investigators can become more effective in managing risk and understanding why outbreak events unfold, thus providing a basis for improved risk management. Those concepts include:

- understanding that the deep underlying interactions of all forces that make up a system is key to influencing or changing that system;
- all systems have 'set points' or set outcomes that are predetermined by the nature of these underlying interactions;
- changes to complex systems require a great deal of information about the nature of these underlying interactions; and
- unless this deeper understanding is achieved, efforts to change the system will ultimately fail and the system will return to its 'set point.'

Whether a facility food safety manager, regulatory inspector, or outbreak investigator, all have experienced either the cycle of making a food safety correction, only to see it occur repeatedly or having the same food facility involved in more than one or two foodborne outbreak investigations. Using Bertalanffy's concepts can help move foodborne outbreak investigation and food safety programs away from these cycles that do not support food safety.

Farm-to-Fork Continuum and Food Systems

The FBIO environmental assessment occurs within the context of the farm-to-fork continuum, sometimes referred to as the food chain. The farm-to-fork continuum represents how food flows from its source through processing or manufacturing, distribution, and finally to the point of final service, which may be a retail establishment such as a restaurant or a consumer's home. The source is where the food originates. It may include a farm where produce is grown or a sea where fish are harvested. Processing or manufacturing includes all the steps along the continuum that prepare the food for distribution. This point in the continuum may be as simple as washing whole produce or as complex as pasteurization or low-acid canning. Distribution includes everything from storage and warehousing to repacking, reprocessing, and transporting to the next point in the continuum. Sometimes distribution involves multiple points along the farm-to-fork continuum. Finally, the concept of point of final service includes any points where foods are purchased and/or consumed, such as grocery stores, restaurants, and delis, or the home.

Each point in the farm-to-fork continuum represents its own unique system (Figure 1). Although the systems themselves are unique, they all consist of the same components:

- Inputs – items that enter the system.
- Processes, steps, and methods to which the inputs are subjected.
- Internal system variables – factors that exert positive, negative, and neutral effects on all other aspects of the system.
- Outputs – immediate results of the system.
- Outcomes – what happens as a result of the outputs.
- Feedback to that particular system on the basis of the outcomes (Figure 2).

Food Systems

Inputs and Processes

At the source, inputs might include the weather, soil conditions, and the hydrology of the watershed as it relates to irrigation source water, type or breed of animal, organisms, and/or chemicals inherent to the product or from the environment. Inputs at subsequent points along the farm-to-fork continuum will include much more than circumstances directly related to food safety such as ingredients for the final product that include organisms or chemicals that may or may not be harmful if consumed. They could include infusions of financial and human capital or other elements that are less obvious, such as management structures that do not support a food safety culture within the establishment.

The flow of food through such processes as storing, cooking, etc. to which inputs are subjected at different points along the farm-to-fork continuum provides a road map for the environmental assessment at that particular point in the continuum. It is essential to describe the related processes step by step, from receipt of ingredients through disposition of the final product or output, whether that is shipping the product to the next stop on the farm-to-fork continuum or to final service or consumption. There may be a few processes involved or many, depending on the complexity of the food product. Using the establishment's HACCP plan, if there is one, also helps identify potential or real hazards, CCPs, and CLs along the way. Mapping the flow of food through processes is necessary for identification of contributing factors (Figure 3). This basic mapping of the flow of food through the establishment's food processes is the total extent of many foodborne outbreak environmental assessments. However, to understand the environmental antecedents, the internal system variables must be examined.

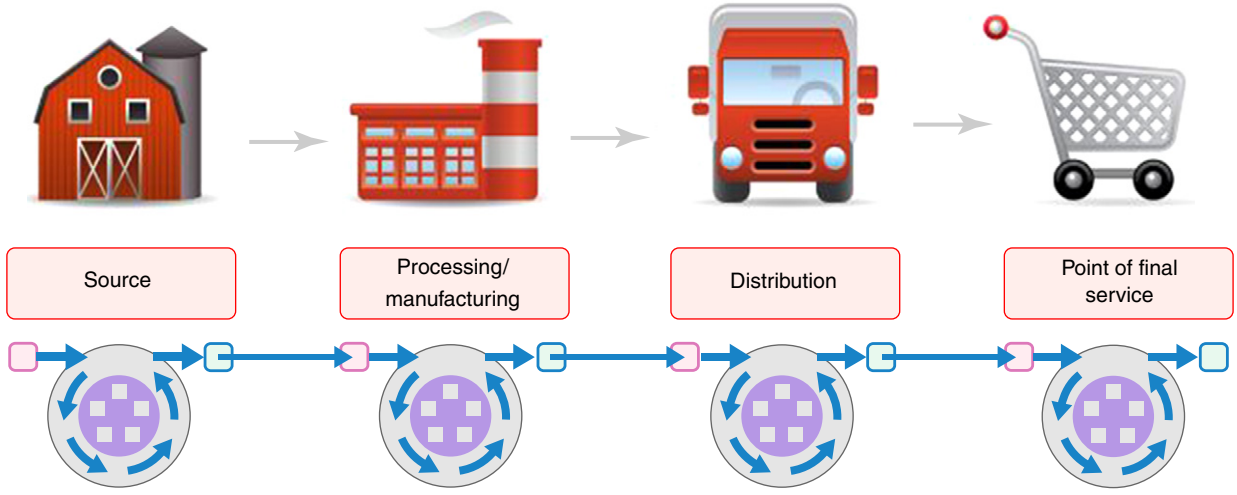

Figure 1 Farm-to-fork continuum.

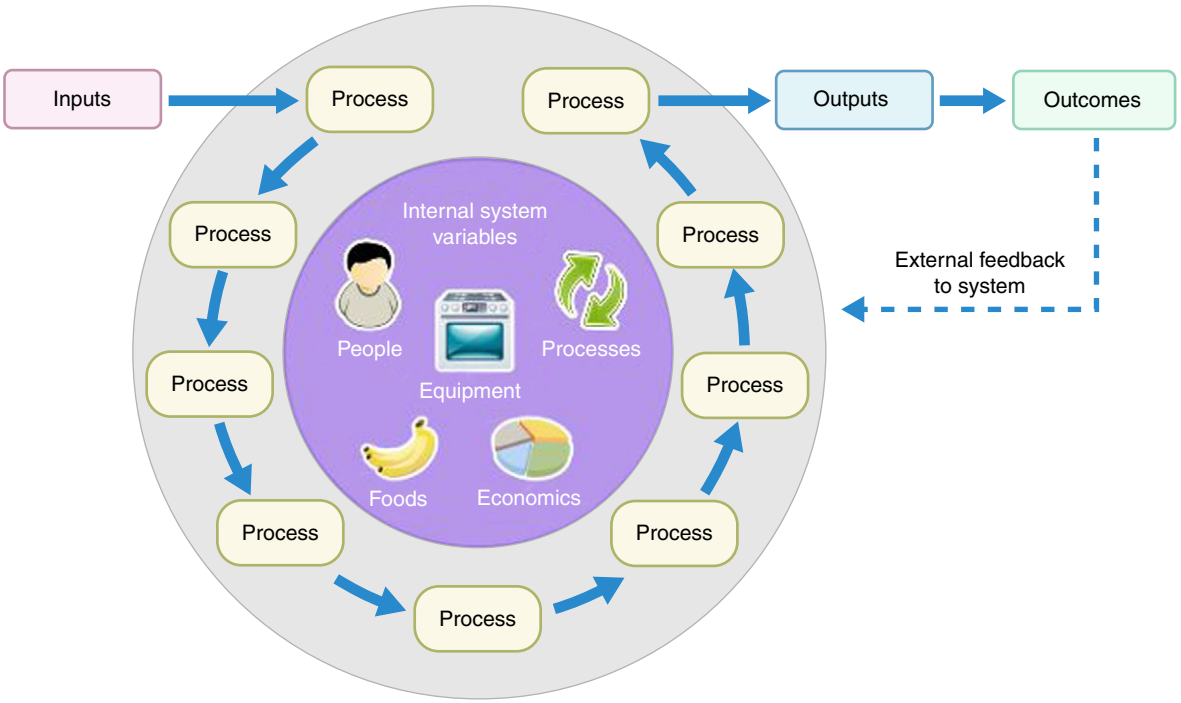

Figure 2 System components.

Internal System Variables

Understanding internal system variables and especially their interactions with each other is important to understand how the system operates and why it operates the way it does. Knowledge of these variables and their interactions can also lead to an informed analysis of the degree of control exerted over critical food safety hazards. It can also explain how, in various circumstances, that degree of control may change. Although no system is completely safe or unsafe, properly managing internal system variables helps to influence the system's outcome toward a safe product.

Internal system variables include:

- People
- Equipment
- Processes
- Foods
- Economics (Figure 2).

These are variables currently recognized as having the greatest influence on food safety. Understanding these variables and their influences helps in determining why the outbreaks occurred. The internal system variables and their potential influences on food safety are complex; on any given day, they may have a positive, negative, or neutral influence on food safety within a particular system in the farm-to-fork continuum. The environmental assessment team must determine the role of these variables during its investigation.

The people, as an internal variable, exert the greatest influence on all aspects of the system at any point in the farm-to-fork continuum, from inputs through outcomes. This internal system variable refers to the individuals working at any point in the continuum and the food safety culture within which they work. The food safety culture at any point in the farm-to-fork continuum is reflected by such things as the owner's/manager's/supervisor's knowledge and commitment to food safety, the existing written standard operating procedures, HACCP plans that include monitoring, the recordkeeping and corrective actions, the supervision of employees, etc. The people variable also refers to how an individual is inclined to behave and how an individual interprets standard operating procedures. For example, some food workers are not inclined to view diarrhea as an illness, and therefore they do not report it to management.

The internal system variable equipment refers to the physical layout of the facility and the equipment appropriate to that point in the farm-to-fork continuum. To support safe food practices, the equipment must be properly designed and constructed for its intended purpose. It must be properly located, not only for its proper operation but also for its facilitation of the most efficient work flow for the processes involved. Proper installation also requires adequate space in the facility to accommodate both the equipment and the work flow in the facility. In addition, equipment that is not properly maintained can potentially exert a negative influence on food practices and CLs. Finally, poorly located or maintained equipment may also influence workers to develop procedures independently to work around the problems caused, thus negatively influencing CLs (Figure 4).

The internal system variable processes refer to the inherent qualities of processes but not to such actual food-processing steps as cooking, holding, storing, etc., as depicted in the flow of food at any point along the farm-to-fork continuum. Although a process may be capable of delivering a safe end result, the inherent nature of the process may pose circumstances that negatively influence the safety of the system. An example is the complexity of the process. A

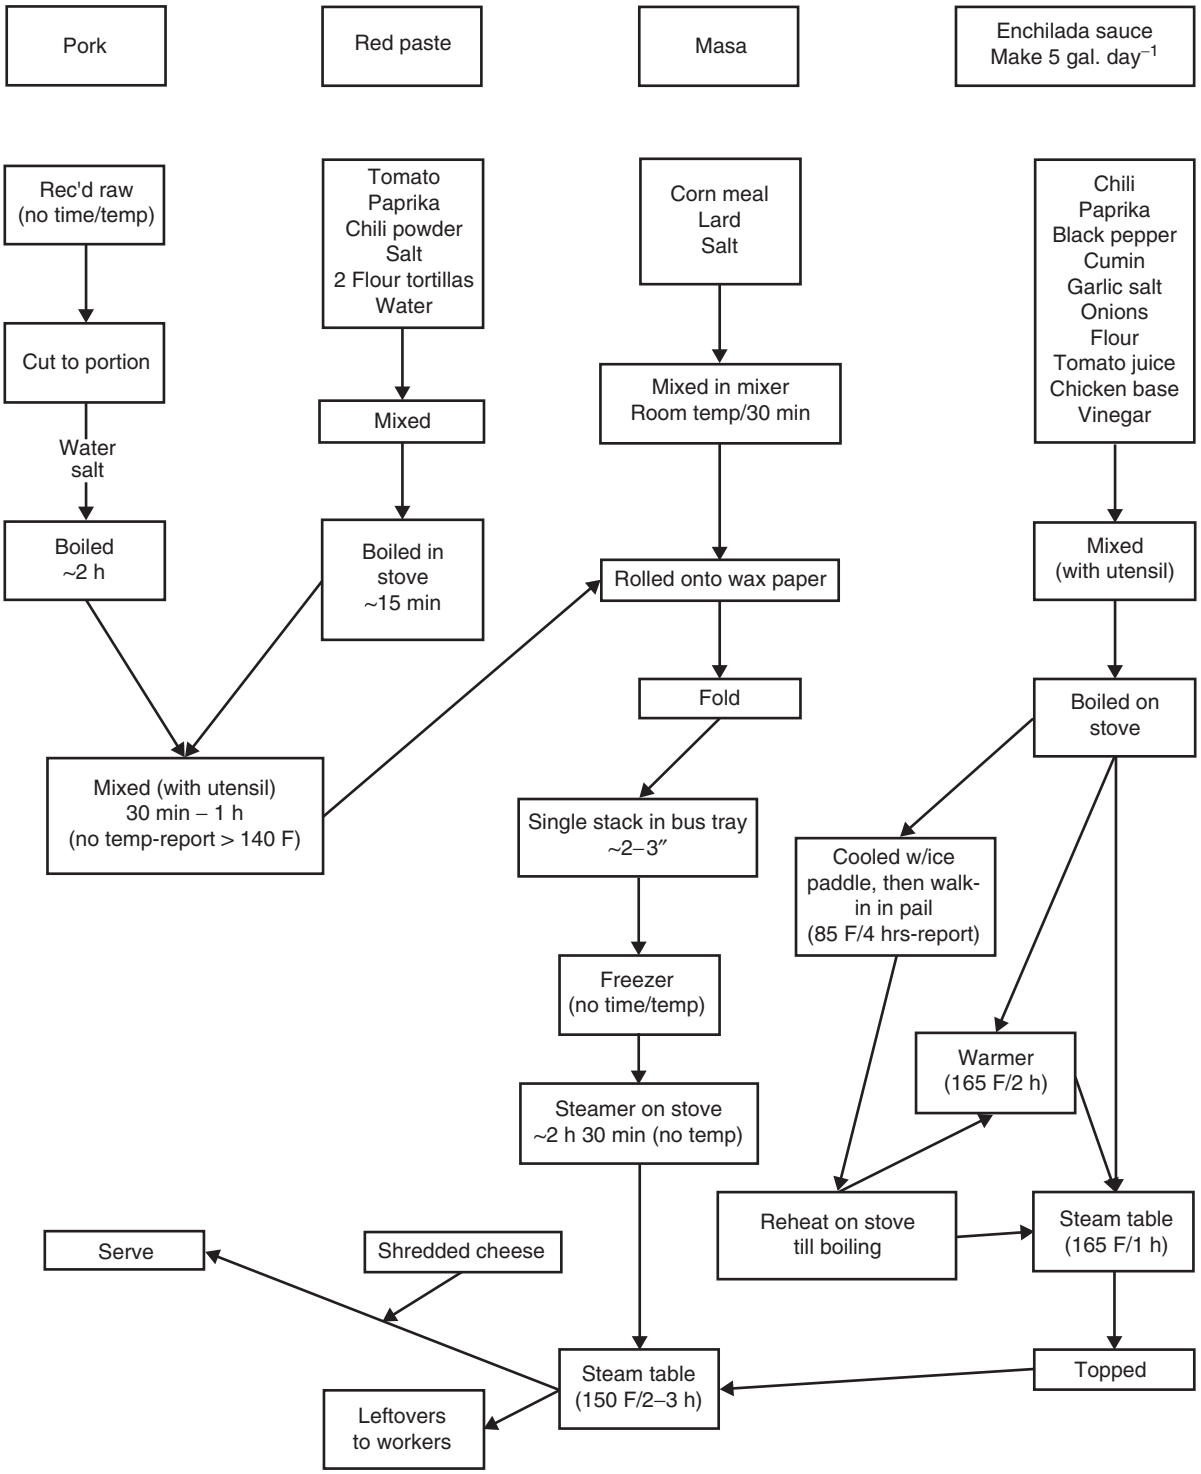

Figure 3 Food flow.

process that is highly complex may pose many risks for contamination or for survival or proliferation of the agents that cause foodborne illness. Industry efforts to reduce the complexity of processes can be found at many points along the farm-to-fork continuum. For example, a manufacturer or restaurant manager may remove steps from a complex process to make it as simple as possible. By changing the inherent nature of the process from complex to simple, a manufacturer or restaurant manager reduces opportunities for contamination or for survival or proliferation of agents. However, complexity of a process is more obvious than other examples, such as the influence of traditions in food

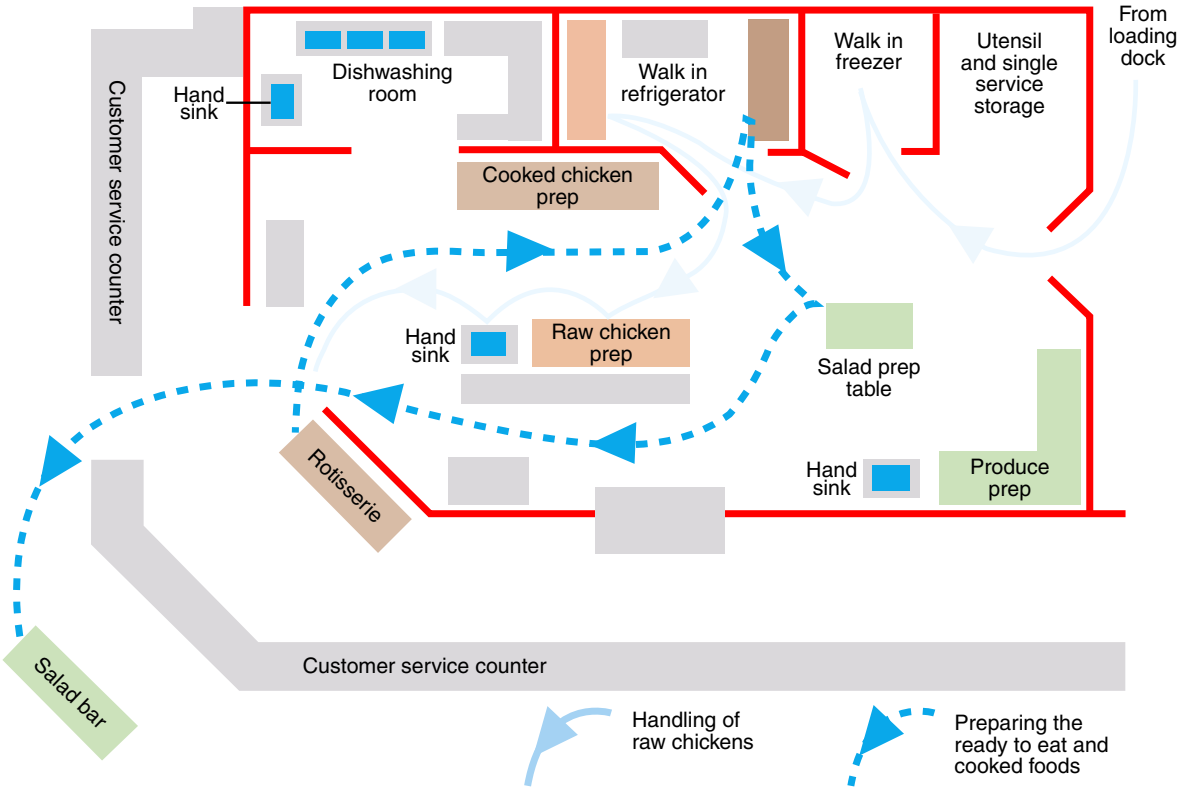

Figure 4 Physical facility layout.

processing or when pathogens change rendering the inherent properties of a process from safe to unsafe. A good example is the ability of *Salmonella* to develop a protective barrier that renders low water activity of a process to be ineffective in reducing pathogens.

The internal system variable food refers to the inherent qualities of food that may positively or negatively influence food safety. These qualities include pH, water activity, texture, and viscosity. For example, the texture of leafy greens renders them difficult to clean; the thickness of such a food as refried beans may require specialized cooling practices.

The internal system variable economics refers to issues affecting the costs and profit margins at any point along the farm-to-fork continuum. For example, a restaurant may be required to change its menus to accommodate changes in food trends, and doing so can potentially affect costs and profit margins. Adequate profit margins may allow any point along the farm-to-fork continuum to maintain itself in a way that promotes safe food practices, whereas poor profit margins may contribute to inadequate staffing, training, or maintenance of equipment, all of which can negatively influence food safety.

People, equipment, processes, foods, and economics are the internal system variables currently recognized as being related to food safety. Overtime well-conducted FBIO environmental assessments will identify other important variables.

Outputs, Outcomes, Feedback

The last three system components along the farm-to-fork continuum are outputs, outcomes, and feedback. Outputs are represented by the final food item that moves from one point in the continuum to the next, ultimately including the final product that is consumed by customers. Outcomes include such elements as customer satisfaction, profit, and customer health. These are only a few of the outcomes of the individual systems represented along the farm-to-fork continuum, but they may be most closely related to public health.

Outcomes spark results that are fed back into each system in one way or another. The feedback may prompt changes within an individual system or in the larger farm-to-fork continuum. For example, feedback on customer satisfaction may trigger a change in menu at a restaurant, or a change in the production of a particular food at manufacturing; feedback on profits may trigger a change in practices or processes at any point along the continuum. Finally, feedback from large foodborne outbreak events can result in system changes at each point in the farm-to-fork continuum.

Although the individual food systems along the farm-to-fork continuum are unique, they are interrelated. Each point affects food safety of any subsequent points along the continuum. A breakdown in food safety at any point along the continuum can contribute to an outbreak of foodborne illness (Figure 1).

Internal System Variable Interaction

It is important to understand all the components within an individual system, whether that system resides at the farm, the manufacturing plant, in the distribution, or at the point of final service. But it is especially important to understand the

internal system variables, because these variables exert such strong influences on every aspect of the individual food system, from inputs through outcomes, including customer health. Specifically, the internal variables can pull the system toward a safe or an unsafe outcome – or sometimes, in varying degrees, toward both a safe and an unsafe outcome. Understanding these variables, and especially their interactions with each other, is pivotal to understanding how an individual system operates and why it operates the way it does. Knowledge of these variables and their interactions can also lead to an informed analysis of the degree of control that system managers have over food safety hazards. It can also facilitate an analysis of how, in various circumstances, that degree of control may change. Properly managing the underlying variables helps to pull the individual system's outcome toward a safe product. But it is important to understand that no individual food system is ever completely safe or unsafe. Instead, the system 'tends' to be safe or unsafe. A simple analogy can clarify this point.

If a room's thermostat is set at 70 F, then 70° is the system's set point, the point the system will attempt to maintain. The heating and cooling mechanisms will work to keep the temperature at 70°. It will try to maintain this temperature in spite of the negative effects of some of the system's internal variables, such as insufficient attic or window insulation or improperly sealed doors.

If it is cold outside and a door is opened, the temperature may temporarily drop to 65°. That is because opening the door overwhelms the set point of the system. However, once the door is closed, the system works to regain the set point in spite of its internal variables' negative influences.

Understanding a system and how it reacts to internal variables is important. In the case of a room with a heating and cooling system, an open window will not change the thermostat setting. The thermostat will try to help the room regain its set point, which is what all systems do. It is important to understand that the system's set point is one condition that, together with internal variables, is influenced by positive and negative factors. Successfully changing the system's set point, if that is necessary, requires understanding these variables and their influences.

The internal variables influence the individual food systems described along the farm-to-fork continuum. Each of these variables may have a positive, negative, or neutral influence on food safety at any given point in time, and yet the food system works to remain at its set point. However, if the negative effects of one or more variables overwhelm the other variables' positive or neutral influences, the result can be contamination and/or survival or proliferation of an etiologic agent in food, to such an extent that an FBIO occurs.

For one to determine contributing factors and environmental antecedents, the interactions of these variables with each other and within the individual food system itself must be understood. Such an understanding provides the information required to strengthen internal system variables and if necessary change the food safety system's set points, thus reducing the opportunity for a similar outbreak to occur. Over time, data from foodborne outbreak environmental assessments can be compiled, analyzed, and trends determined and provided to decision makers to inform food safety policy development.

Environmental Assessment

Environmental assessment, as a part of an FBIO investigation, is different from other environmental/food safety inspection activities at food establishments. An FBIO environmental assessment reconstructs past events. It is triggered by an outbreak of foodborne illness. It describes the outbreak influences of people, equipment, processes, food, and economics on variables that may have contributed to the outbreak. This assessment identifies contributing factors and environmental antecedents to the outbreak. It is a forensic process that looks at clues and data to develop an hypothesis regarding the cause of the outbreak and to implement appropriate controls to prevent future outbreaks.

By contrast, routine regulatory inspections involve the present – what an inspector can observe or measure at the time of the visit and what violations of regulations can be cited. Routine regulatory inspections involve documenting current conditions at the establishment to provide snapshots of observable conditions at the time of the inspection. It may be risk based – that is, focused on risks that are most likely to cause foodborne illness – and it is conducted when specific information is not available to suggest that any process is out of control. This activity should also be based on an environmental assessment, one that is conducted in the present.

A plan review/HACCP development inspection focuses on future operations at a facility. It identifies potential problems before they lead to a foodborne illness, and it identifies control points for preventing foodborne illness in the future. It allows the facility to evaluate plans and procedures. This activity should also be based on an environmental assessment, one that is conducted on the basis of expectations of the future.

FBIO Environmental Assessment

An FBIO environmental assessment is an in-depth, multidisciplinary, systems-based approach to determine how the environment contributed to the introduction and/or transmission of the agent that caused illness. The environment can include everything external to the host, including air, food, water, animals, plants, climate, etc., as well as people and social and built environments.

The objectives of an assessment are to identify contributing factors and environmental antecedents, as well as to generate recommendations for informed interventions. Contributing factors are divided into three categories:

- Contamination
- Survival
- Proliferation/amplification

Contamination factors refer to how an etiologic agent got onto or into the food vehicle. Examples of contamination factors include a contaminated ingredient or bare-hand contact by a food handler/worker/preparer suspected to be infectious.

Survival factors refer to processes or steps that would have eliminated or reduced an etiologic agent if conducted properly. Although survival factors primarily relate to bacterial outbreaks, under limited circumstances they may be appropriately cited in viral outbreaks as well. For example, although norovirus is more heat resistant than most bacteria, it can be inactivated by cooking processes (185 °F/85 °C for 5 min or boiling for 1 min). As a result, depending on the cooking processes involved, citing survival of the agent as a contributing factor in an outbreak can be appropriate. Examples of survival factors include insufficient time and/or temperature during cooking/heat processing or insufficient time and/or temperature during reheating.

Proliferation/amplification factors identify how an etiologic agent was able to increase in number and/or produce toxic products before the vehicle's being ingested. These factors relate only to bacterial outbreaks. Examples of proliferation/amplification factors include improper cold or hot holding of foods or inadequate processing, such as acidification, water activity, or fermentation.

Environmental antecedents are directly related to contributing factors. They explain why the outbreak occurred and are often referred to as the root causes of outbreaks. For example, a worker who cooks food may not speak the native or primary language of food managers or supervisors. This language barrier may limit the worker's ability to understand food safety training properly, thus resulting in improper cooking of food.

FBIO environmental assessments are best accomplished with a team approach. Team members will vary depending on the setting and the expertise needed, but the team can include such specialists as microbiologists, epidemiologists, water experts, environmental health specialists, food technologists, and veterinarians. The team must understand the farm-to-fork continuum, the systems that make up each point along the continuum, and the interrelationship between different points on the continuum. They must be able to think critically as they filter through information once it evolves over the course of the outbreak investigation, describe each system relevant to the outbreak event, determine the most likely contributing factors and environmental antecedents, and provide recommendations for informed interventions.

Recommendations for informed intervention are based on the findings of the FBIO environmental assessment. These recommendations may be implemented during the environmental assessment in order to stop the outbreak and prevent the further spread of the agent, and/or they may result in the development of longer term strategies to reduce the likelihood of future outbreaks. Immediate steps taken might include destroying food or taking steps to stop its distribution, excluding food workers who are ill, or closing the facility. Longer term strategies might include development and implementation of an HACCP plan or updating and implementing policies regarding identifying and managing food workers who are ill with such symptoms as diarrhea, vomiting, and/or fever.

Challenges Encountered in an FBIO Environmental Assessment

There are four important challenges sometimes encountered in the course of conducting an environmental assessment: the ability to think critically; timing; distinguishing between regulatory violations and factors and antecedents that contribute to foodborne outbreaks; and the seasonal nature of growing foods.

The foodborne outbreak environmental assessment is complex, requiring a high level of critical thinking skill among team members to determine the most likely contributing factors and environmental antecedents in an outbreak event. Each point along the farm-to-fork continuum represents its own unique individual food system, but the systems are interrelated. Therefore, an outbreak of foodborne illness that appears related to one part of the continuum can actually be the result of a food safety breakdown in another part of the continuum. The team must continuously assess an outbreak event, not only in terms of the immediate system under scrutiny but also in terms of the other systems in the farm-to-fork continuum. Such an assessment requires a continuous and iterative analysis and assessment of current thinking within the team as information is gathered and premises are revisited until the team is convinced that the best possible conclusions have been reached. Objectively and continuously evaluating a hypothesis based on information gathered at a point in time during a foodborne outbreak event is one of the most challenging aspects of critical thinking during an environmental assessment. Developing such an hypothesis requires giving equal weight to information that weakens a favored hypothesis and information that supports it. After all, human nature renders it difficult to prove yourself wrong. Therefore, evidence that conflicts with assumptions tends to be discounted. During an environmental assessment, it is human nature to seek information that confirms a hypothesis, rather than information that refutes it. There is a tendency to believe what is expected to be believed. Such a tendency can lead to flawed or inaccurate conclusions.

Another important challenge is timing. Agencies may become aware of an FBIO when it is over or nearly over. Affected persons may no longer be sick, and they may have a hard time remembering what they ate, thereby making it difficult for epidemiologists to identify the vehicle. Food preparation may have been days or weeks earlier, and management and food workers may have a difficult time remembering what actions they took. Investigators try to reconstruct what happened and why food workers acted the way they did, but the workers may not be able to give investigators a complete picture. Therefore, agencies must act quickly when they receive a report that an outbreak may have occurred.

Differentiating between violations of regulations and variables that may have led to an outbreak represents another significant challenge. A food establishment system has its own set point at which some level of regulatory compliance occurs on a day-to-day basis. At any point in time, violations of regulations may be present, but such violations may not result in an FBIO. An FBIO is usually the result of a convergence of factors, and investigators must focus on determining the specific system variables that led to the outbreak. These variables are often associated with a regulatory requirement, but some variables may not be. At the same time, there may be multiple regulatory violations that are unrelated to the FBIO event. For example, floors, walls, and ceilings of a food establishment

that are in poor repair or are dirty are likely violations of food regulatory requirements and are likely to be noted during a routine inspection. However, during an environmental assessment, these things may be noted as part of a general description of the establishment, but they are not at all likely, for instance, to be related to a *Clostridium perfringens* or a *Staphylococcus aureus* outbreak.

Finally, the growing, harvesting, and processing activities for implicated commodities may have ceased for seasonal operations by the time an environmental assessment is being started. Such a cessation means that investigators cannot observe operations or conditions that might have contributed to the outbreak.

Conclusion

Although there have been improvements in FBIO investigation and reporting, the reports still leave many questions regarding environmental causes of outbreaks. Environmental assessments are a critical part of the FBIO response. Unfortunately, information from FBIO environmental assessments, if they are conducted, is sometimes missing or minimally supplied in subsequent publications on specific FBIOs or in outbreak surveillance systems. A compilation and analysis of environmental causes of FBIOs provides the data needed to inform public policies, procedures, and training at the point(s) involved along the farm-to-fork continuum; such a compilation also identifies research gaps and evaluates the impact of food safety programs in reducing the risks of FBIOs. All these benefits, however, depend on a standard method or approach to conducting an FBIO environmental assessment and to reporting and analyzing the data from FBIOs.

In 1999, the US Centers for Disease Control and Prevention (CDC) began to explore using a systems approach, as described in this article, during FBIO environmental assessments. This approach was further explored by state and local food safety programs participating in the CDC Environmental Health Specialists Network and by the US Food and Drug Administration (FDA). As a result, the US FDA began conducting systems-based environmental assessments in 2011 during that agency's foodborne outbreak responses. In 2002, the US National Park Service Public Health Program began its exploration of a systems approach for its field assessments of foodservice establishments. The Park Service continues to work with this approach to determine if it can help regulators and food managers gain additional control over food safety issues.

In 2013, CDC will launch an e-learning program on how to conduct an FBIO environmental assessment. This training program will be required of participants who report assessment data to the National Voluntary Environmental Assessment Information System (NVEAIS), an expansion of the existing CDC FBIO reporting system. This new reporting system is expected to help identify factors that can be routinely monitored to prevent or reduce the risk for FBIOs. By building on the foundation of a standard method for FBIO environmental assessments, NVEAIS provides a basis for understanding and preventing future outbreaks, as opposed to simply responding to them.

Safe Use of Wastewater for Agricultural Production

KO Medlicott and R Bos, World Health Organization, Geneva, Switzerland

Glossary

Health-based target A defined level of health protection for a given exposure. This can be based on a measure of disease, for example, 10^{-6} DALYs per person per year, or the absence of a specific disease related to that exposure.

Log reduction Organism removal efficiencies: 1 log unit = 90%; 2 log units = 99%; 3 log units = 99.9%; and so on.

Multiple barriers Use of more than one preventive measure as a barrier against hazards.

Operational monitoring The act of conducting a planned sequence of observations or measurements of control parameters to assess whether a control measure is operating within design specifications (e.g., for wastewater treatment turbidity). Emphasis is given to monitoring parameters that can be measured quickly and easily and which can indicate if a process is functioning properly. Operational monitoring data should help managers to make corrections that can prevent hazard breakthrough.

Restricted irrigation The use of wastewater to grow crops that are not eaten raw by humans.

Risk The likelihood of a hazard causing harm in exposed populations in a specified timeframe, including the magnitude of that harm.

Unrestricted irrigation The use of treated wastewater to grow crops that are normally eaten raw.

Validation Testing the system and its individual components to prove that it is capable of meeting the specified targets (i.e., microbial reduction targets). Should take place when a new system is developed or new processes are added.

Verification monitoring The application of methods, procedures, tests, and other evaluations, in addition to those used in operational monitoring, to determine compliance with the system design parameters and/or whether the system meets specified requirements (e.g., microbial water quality testing for *Escherichia coli* or helminth eggs, microbial, or chemical analysis of irrigated crops).

Introduction

Domestic wastewater is increasingly used for agriculture in both developing and industrialized countries. In developed nations, wastewater is typically used under controlled conditions after secondary and, most often, tertiary treatment. However, in developing countries the greatest proportion of wastewater use is with raw or partially treated wastewater applied either directly or indirectly in diluted form from polluted rivers and streams.

The value of wastewater has long been recognized by farmers worldwide. It is less affected by seasonal variations than rivers and streams and can provide a reliable year-round source of water. It also contains the nutrients necessary for plant growth. The use of wastewater in agriculture is a form of nutrient and water recycling, which can reduce downstream environmental impacts on soil and water resources.

However, wastewater also contains waterborne pathogens found in the local population and can promote the spread of water-related vectorborne diseases, if not managed carefully. In addition, if the wastewater contains a substantial amount of industrial component chemicals, it may affect soil conditions and plant growth as well as having potential impacts on human health.

Growing competition between the agricultural and urban uses of high-quality freshwater supplies, particularly in arid, semiarid, and densely populated regions, will increase the pressure on this ever-scarce resource. The concept of 'water fit for purpose' is increasingly important in this context: Wastewater use for agriculture will substitute high-quality freshwater, which can instead be used for urban piped water consumers. Within the next 50 years, more than 40% of the world's population will live in countries facing water stress or water scarcity.

In Africa and Asia, the urban population is predicted to double between 2000 and 2030. As these urban and periurban populations grow, the amount of wastewater produced and demand for food, fiber, and freshwater will grow proportionately. This presents urban planners with the challenge to make cost-effective use of resources and provide sufficient quantities of safe food and water to cities. These combined factors are leading to a growing understanding of the value of wastewater as a resource for agricultural production rather than as a waste product.

The third edition of the World Health Organization (WHO) Guidelines for the Safe Use of Wastewater, Excreta and Greywater in Agriculture and Aquaculture provides a summary of the evidence of health impacts from use of

waste-water, excreta, and greywater, and put forward a health risk assessment and management approach. The approach is a departure from the earlier concept of fixed guideline value and norms for wastewater quality: it incorporates multiple barriers along the sanitation chain rather than rigid treatment quality thresholds, and starts with the establishment of viable health-based targets. This article provides a summary of Volume II of the Guidelines: Safe Use of Wastewater in Agriculture.

Health Risks Associated with Wastewater Use

Wastewater is likely to contain a variety of pathogens, many of which are capable of survival in the environment (in the wastewater, on the crops, or in the soil) long enough to be transmitted to humans.

Health risks may manifest directly as outbreaks of food-, water-, and vectorborne diseases or less visible yet persistent diseases such as helminth infections, and noncommunicable diseases resulting from exposure to industrial waste containing heavy metals. Indirect health effects are also possible through contamination of drinking water sources with nitrates or by causing the production of toxic cyanobacteria. However, there are also significant potentially positive health effects from improved food supply and nutrition in arid and food-insecure areas.

The greatest health risks are associated with crops that are cultivated in close proximity to the soil and are eaten raw, such as salad crops, onions, and radishes. Intestinal helminths are the most likely infection in places where wastewater is used without adequate treatment due to the long survival time of their eggs, up to several years in water and soil. Studied viruses, bacteria, and protozoa have shorter survival times in water of usually less than 10–70 days. Factors that affect survival of pathogens in the environment include humidity, temperature, soil content, pH, ultraviolet radiation levels, plant and foliage type, and competition with other native flora and fauna.

Information available from epidemiological studies of infectious disease transmission related to wastewater use in agriculture is summarized in Table 1.

The Stockholm Framework and Health-Based Targets

The Stockholm Framework is an integrated approach that combines risk assessment and risk management to control water-related diseases. The approach allows countries to develop health-based guidelines and standards for water- and sanitation-related microbial hazards within a harmonized framework.

The framework includes health risk assessment followed by setting of health-based targets and the development of national guideline values, best practice, and agreed control approaches together with evaluation of the impact of these combined controls on the stated public health objectives. A

Table 1 Summary of health risks associated with the use of wastewater for irrigation

Group exposed	*Health threats*		
	Nematode	*Bacteria/viruses*	*Protozoa*
Consumers	Significant risk of *Ascaris* infection for both adults and children with untreated wastewater	Cholera, typhoid, and shigellosis outbreaks reported from use of untreated wastewater; seropositive responses for *Helicobacter pylori* (untreated); and increase in nonspecific diarrhea when water quality exceeds 10^4 thermotolerant coliforms per 100 ml	Evidence of parasitic protozoa found on wastewater-irrigated vegetable surfaces, but no direct evidence of disease transmission
Farm workers and their families	Significant risk of *Ascaris* infection for both adults and children in contact with untreated wastewater; risk remains, especially for children, when wastewater treated to <1 nematode egg per liter; and increased risk of hookworm infection in workers	Increased risk of diarrheal disease in young children with wastewater contact if water quality exceeds 10^4 thermotolerant coliforms per 100 ml; elevated risk of *Salmonella* infection in children exposed to untreated wastewater; and elevated seroresponse to norovirus in adults exposed to partially treated wastewater	Risk of *Giardia intestinalis* infection was insignificant for contact with both untreated and treated wastewater; increased risk of amebiasis observed with contact with untreated wastewater
Nearby communities	*Ascaris* transmission not studied for sprinkler irrigation, but same as above for flood or furrow irrigation with heavy contact	Sprinkler irrigation with poor water quality (10^6–10^8 total coliforms per 100 ml) and high aerosol exposure associated with increased rates of infection; use of partially treated water (10^4–10^5 thermotolerant coliforms per 100 ml or less) in sprinkler irrigation is not associated with increased viral infection rates	No data on transmission of protozoan infections during sprinkler irrigation with wastewater

Source: Reproduced with permission from WHO (2006b).

health-based target can be based on a standard metric of disease, such as a disability-adjusted life year (DALY) (e.g., 10^{-6} DALYs lost), or it can be based on an appropriate health outcome, such as the prevention of the transmission of vectorborne diseases resulting from exposures to wastewater used in agricultural practices.

The Stockholm Framework provides the conceptual framework for the WHO Guidelines for the Safe Use of Wastewater, Excreta and Greywater and other WHO water quality-related guidelines. The WHO Guidelines for Drinking Water Quality recommend a target of 10^{-6} DALYs lost, and this is also adopted within the Safe Use of Wastewater Guidelines on the premise that consumers should reasonably expect food to be as safe as drinking water. However, countries may opt for a lower target of 10^{-4} or 10^{-5} DALYs lost in situations where the disease burden is high and other water, sanitation and hygiene interventions may be more effective.

The Multiple-Barrier Approach to Achieve Health-Based Targets

To achieve a health-based target, a range of health protection measures need to be developed along the wastewater treatment and use chain. The target may be achieved entirely in the treatment step, but in situations where treatment is poor or nonexistent the 2006 WHO Guidelines allow flexibility for the target to be met through a combination of subsequent health protection measures. This is the essence of what is commonly referred to as the multiple-barrier approach.

A health-based target of 10^{-6} DALYs is equivalent to a total of 6–7 log reductions of pathogens from the point of waste generation to the point of contact with humans. Figure 1 illustrates different combinations of health protection measures that can be used to achieve the 10^{-6} DALYs or 6–7 log reductions for excreta-related diseases.

As shown in Figure 1, a variety of health protection measures can be used to reduce health risks to consumers, workers and their families, and local communities to meet the health-based target.

The following health protection measures have an impact on product consumers:

- *Wastewater treatment*: Waste treatment methods include primary treatment such as septic tanks, primary and secondary sedimentation tanks, anaerobic sludge blanket reactors, aerated lagoons, or low-rate processes such as constructed wetlands. In some cases, tertiary treatment steps for disinfection and nutrient removal are included. Wastewater treatment can reduce exposure to pathogens by 1 to >6 log units depending on the treatment methods selected and efficiency of operation.
- *Crop restriction*: It requires that wastewater is not used for crops that are eaten raw or nonfood crops such as cotton. Food consumers are protected through subsequent food processing or cooking. Crop restriction can only be used in circumstances where there is a strong enforcement and management of restrictions and profitable restricted crop options exist in the local market conditions.

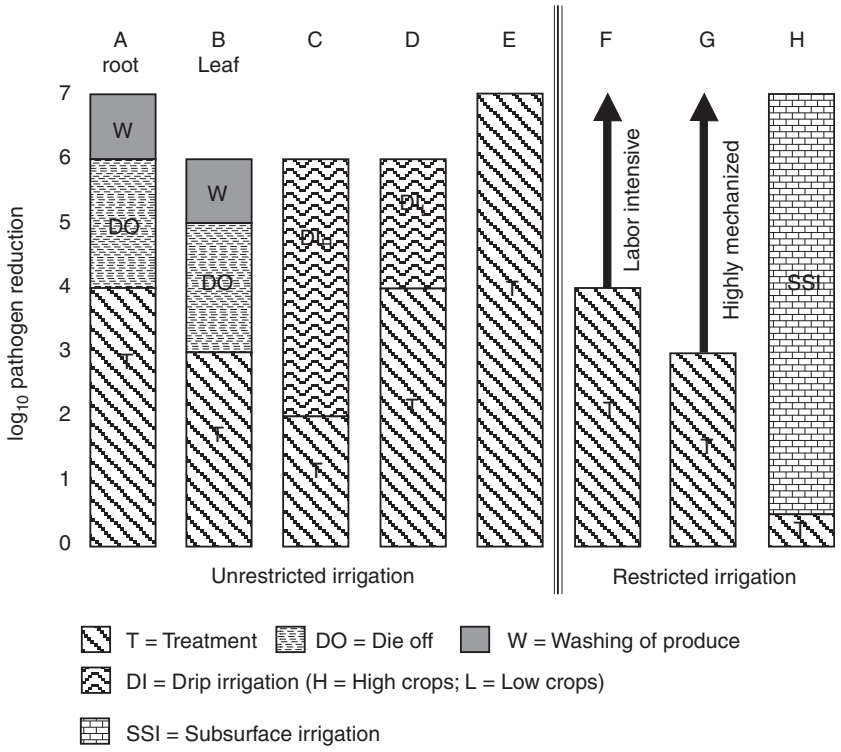

Figure 1 Examples of options for the reduction of pathogens by different combinations of health protection measures that achieve the health-based target of $\leq 10^{-6}$ DALYs per person per year. Reproduced with permission from WHO (2006b).

- *Wastewater application techniques that minimize contamination*: Techniques such as drip irrigation, subsurface irrigation, spray drift control, and enforcement of spray buffer zones can greatly decrease the contact of wastewater with edible parts of the crop, workers, and surrounding communities. Localized irrigation systems and subsurface irrigation can substantially reduce exposure to pathogens by 2–6 log units.
- *Withholding periods to allow pathogen die-off after the last wastewater application*: Allowing 1–2 weeks between the last application of wastewater and harvesting effectively reduces crop contamination by providing time for pathogen die-off naturally. The interval between final irrigation and consumption reliably reduces pathogens by approximately 1 log unit per day. Freshwater can be used for irrigation during the withholding period if needed.
- *Hygienic practices at food markets*: Hygienic practice at market is needed to prevent recontamination of produce. Safe water should be provided at markets for washing and freshening produce and regular inspections to be conducted by food safety authorities to ensure that proper procedures are being used at markets or restaurants where products are prepared.
- *Health and hygiene promotion*: Targeted hygiene promotion programs are required to inform food handlers in their homes, restaurants, and markets on how and why they should wash, disinfect, peel, or cook wastewater-irrigated produce effectively and prevent recontamination.
- *Produce washing, disinfection, and cooking*: Washing of rough-surfaced crops such as lettuce and parsley and vegetables eaten raw in safe water reduces bacteria by at least 1 log unit. For smooth-surfaced crops such as tomatoes, the reduction is approximately 2 log units. Washing in a disinfectant solution and rinsing in safe water can reduce pathogens by 1–2 log units. Peeling fruits and root vegetables reduces pathogens by at least 2 log units. Immersion in boiling or close to boiling water until the food is cooked ensure pathogen destruction.
- *Chemotherapy and immunization*: Immunization for most water-related diseases is currently not possible. However, immunization programs for poliovirus and typhoid and chemotherapy treatment of intestinal helminths and schistosomiasis can complement other control measures above in providing palliative health protection, provided they are applied at the appropriate frequency.

Although not directly related to the consumers of wastewater-irrigated food products, the measures for the protection of farm workers and their families are also important in addressing the range of public health threats posed by wastewater use. Additional controls that can be effective in protecting farm workers and their families and local communities include:

- use of personal protective equipment;
- access to safe drinking water and sanitation facilities at farms and in local communities;
- disease vector and intermediate host control;
- reduced vector contact;
- restricted access to irrigated fields and hydraulic structures; and
- access to safe recreational water, especially for adolescents.

Risk Assessment and Risk Management Plans

The key concept put forward by the 2006 Guidelines for the Safe Use of Wastewater, Excreta and Greywater and the Stockholm Framework is an integrated risk assessment and risk management approach as the most effective means of consistently ensuring safety in the agricultural application of wastewater.

The approach includes the three components of system and exposure assessment, system management, and system

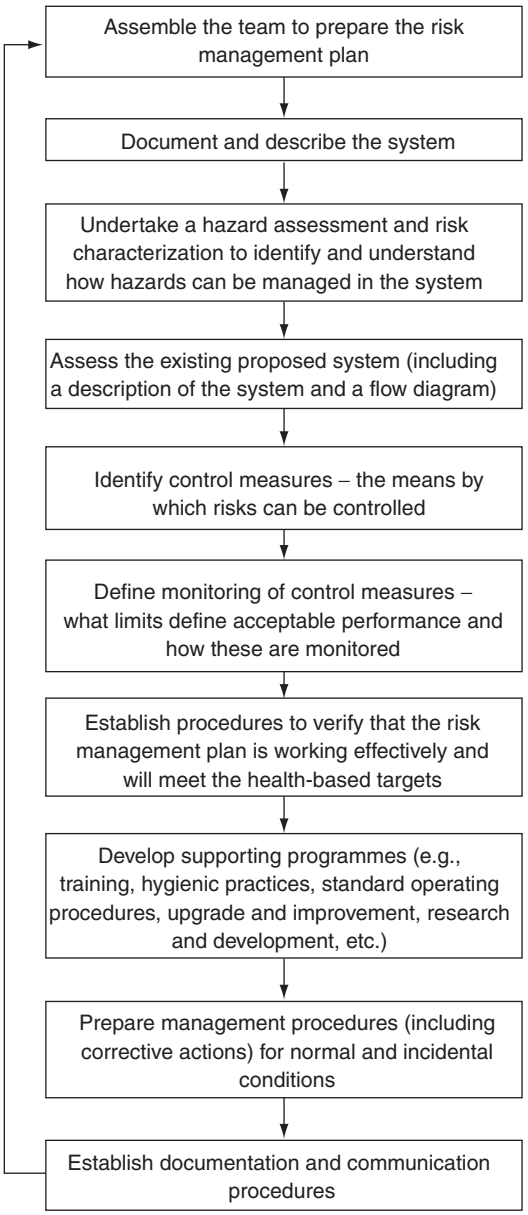

Figure 2 Development of a risk management plan. Reproduced with permission from WHO (2006b).

monitoring, and goes beyond monitoring of effluent quality against the primary management tool.

The approach can be tackled by a multisectoral team representing the wastewater use system from the point of generation to the point of produce consumption using the stepwise process outlined in Figure 2.

The first step in the risk assessment and risk management approach is to establish a system boundary for study and assemble a team of institutional and stakeholder representatives which are responsible for the various elements in the wastewater use chain from generation to use.

The team can then describe the system by generating a flow diagram or geographic map of the system, identifying and describing the path of all fractions of the wastewater through the system as well as the various groups of people at risk of exposure or disease transmission at critical points along the system path. The team should also gather data on the chemical and microbial quality of the wastewater to be used as well as existing surveillance data on waterborne and water-related vectorborne diseases in the area as part of the system description. The system description should also include other relevant contextual information such as water quality standards to be met, certification and auditing requirements, and information on local demographics and land use patterns as well as known weather or seasonal variations that may affect the safe management of the system. All data collected should be validated through onsite investigations.

The team can then assess the hazards, hazardous events, and associated risks at each stage of the system and make an assessment whether the hazard/risk is already adequately managed or not. The prioritization of hazards can then be done using a matrix of likelihood and severity to rate the risk posed by each hazard.

The prioritized risk assessment allows the team to identify new control measures to improve the system in order of the greatest health risk. Ideally, improvements should be targeted as near to the source of the hazard as possible and provide reliable long-term control. However, it may be quicker and more cost-effective to plan for interim controls that are less costly until more comprehensive controls implemented. The improvement plan identifying new and improved control measures is a key output of the risk assessment and risk management process.

The other key output is a monitoring plan. Even if no new controls are identified in the improvement plan, a clear monitoring plan is needed with agreed operational and verification monitoring parameters at critical points in the system. Each monitoring parameter needs to have identified limits and action to be taken in the event these are exceeded.

Operational monitoring parameters mainly include simple measurements that can be carried out on a day-to-day basis to indicate that processes are working as expected. Monitoring of this type relies on simple measurements that can be read quickly so that decisions can be made in time to remedy a problem. Examples of operational monitoring parameters include flow rates and retention times, turbidity, pH, monitoring of types of crops grown, length of withholding periods observed, and adherence to market hygiene and food preparation advice.

Verification monitoring is used to show that the end product (e.g., treated wastewater, crops) meets treatment targets and ultimately the health-based targets. Information from verification monitoring is collected periodically and thus would arrive too late to allow managers to make decisions to prevent a hazard breakthrough. However, verification monitoring can indicate trends over time such as improvements or deterioration of the efficiency of a specific process. Examples of verification monitoring include *Escherichia coli* and helminth egg counts and chemical levels as shown in Tables 2–4 as well as monitoring measures such as analysis of plant contamination levels, hygiene of markets and food preparation areas, and prevalence and intensity of infections in potentially affected populations.

Table 2 Verification monitoring[a] (*Escherichia coli* numbers per 100 ml of treated wastewater) for the various levels of wastewater treatment in Options A–G presented in Figure 1

Type of irrigation	*Option (Figure 1)*	*Required pathogen reduction by treatment (log units)*	*Verification monitoring level (*E. coli *per 100 ml)*	*Notes*
Unrestricted	A	4	$\leq 10^3$	Root crops
	B	3	$\leq 10^4$	Leaf crops
	C	2	$\leq 10^5$	Drip irrigation of high-growing crops
	D	4	$\leq 10^3$	Drip irrigation of low-growing crops
	E	6 or 7	$\leq 10^1$ or $\leq 10^\circ$	Verification level depends on the requirements of the local regulatory agency[b]
Restricted	F	3	$\leq 10^4$	Labor-intensive agriculture (protective of adults and children under 15 years of age)
	G	2	$\leq 10^5$	Highly mechanized agriculture
	H	0.5	$\leq 10^6$	Pathogen removal in a septic tank

[a]Verification monitoring level refers to what has previously been referred to as effluent standards or effluent guideline levels.

[b]For example, for secondary treatment, filtration, and disinfection: 5-day biochemical oxygen demand, <10 mg l^{-1}; turbidity, <2 nephelometric turbidity units; chlorine residual, 1 mg l^{-1}; pH 6–9; and fecal coliforms, not detectable in 100 ml (State of California, 2001).

Source: Reproduced with permission from WHO (2006b).

Table 3 Maximum tolerable soil concentrations of various toxic chemicals based on human health protection

Chemical	*Soil concentration (mg kg^{-1})*
Element	
Antimony	36
Arsenic	8
Barium[a]	302
Beryllium[a]	0.2
Boron[a]	1.7
Cadmium	4
Fluorine	635
Lead	84

PCBs	0.89
Pentachlorophenol	14
Phthalate	13 733
Pyrene	41
Styrene	0.68
2,4,5-T	3.82
Tetrachloroethane	1.25
Tetrachloroethylene	0.54
Toluene	12
Toxaphene	0.0013
Trichloroethane	0.68

[a]The computed numerical limits for these elements are within the ranges that are typical for soils.

Abbreviations: DDT, dichlorodiphenyltrichloroethane; PAHs, poly-aromatic hydrocarbons; PCB, polychlorinated biphenyl.

Source: Reproduced with permission from WHO (2006b).

To ensure the plan is consistently applied the team may need to develop a range of supporting program and management procedures. This may include actions such as operator training programs, development of standardized data collection and reporting formats, development of standard operating procedures taking into account normal and critical incident situations, and public communications and feedback mechanisms.

Crucially the risk management plan should be periodically reviewed and updated as new information becomes available and especially after system upgrades or incidents, or changes in system performance requirements.

Verification Monitoring Levels

The verification monitoring levels shown below and in Tables 2–4 summarize the verification monitoring levels presented in the 2006 WHO Guidelines for the Safe Use of Wastewater, Excreta and Greywater in Agriculture and Aquiculture, Volume II.

For helminth infections, no excess helminth infections for both product consumers and farmers could be measured when wastewater quality of ≤ 1 helminth egg per liter was used for irrigation with the exception of children less than 15 years of age being exposed in the fields.

The 2006 Guidelines for the Safe Use of Wastewater, Excreta and Greywater also generally validated the 1989 WHO Guideline value of 1000 *E. coli* per 100 ml of unrestricted use of wastewater in agriculture but puts forward various monitoring levels based on the type of irrigation used and other control measures in place after the treatment step with reference to the options shown in Figure 1.

The level of chemical pollutants in wastewater is dependent more on crop tolerances than health concerns. Table 3 on good agricultural practice outlines concentrations of chemicals in irrigation water that impact agricultural productivity.

However, over time, application of wastewater with chemical concentrations tolerable to plants may accumulate to levels of soil contamination unacceptable for human health. For chemical exposure, numerical limits for the maximum tolerable pollutant concentration in wastewater-irrigated soils are derived by establishing the acceptable daily human intake for a pollutant. Limits shown in Table 2 are derived from a wastewater → soil → plant → human route.

Sociocultural Considerations

Public perceptions about wastewater use are generally negative and often accompanied by disproportionate fears about chemical exposure over microbial exposure. Well-planned and technically sound projects can fail if managing public perception is not adequately accounted for in the project design.

The multiple-barrier approach requires a greater degree of human behavior change to implement control measures after the treatment step compared to enforcing wastewater treatment thresholds. Health protection measures such as changing irrigation methods, enforcing crop restriction or die-off periods, using personal protective equipment, or market and food hygiene measure all require behavior change that may be more or less easily accepted in differing sociocultural contexts.

Behavioral patterns and the social feasibility of behavior change in order to introduce wastewater use schemes or to reduce disease transmission in existing schemes need to be assessed on an individual project basis. It cannot be assumed

Table 4 Threshold levels of trace elements in irrigation water for crop production

Element		*Recommended maximum concentration*[a] *(mg l^{-1})*	*Remarks*
Al	Aluminum	5	Can cause nonproductivity in acid soils (pH <5.5), but more alkaline soils at pH >7 will precipitate the ion and eliminate any toxicity
As	Arsenic	0.10	Toxicity to plants varies widely, ranging from 12 mg l^{-1} for Sudan grass to less than 0.05 mg l^{-1} for rice
Be	Beryllium	0.10	Toxicity to plants varies widely, ranging from 5 mg l^{-1} for kale to 0.5 mg l^{-1} for bush beans.
Cd	Cadmium	0.01	Toxic to beans, beets, and turnips at concentrations as low as 0.1 mg l^{-1} in nutrient solutions Conservative limits recommended due to its potential for accumulation in plants and soils to concentrations that may be harmful to humans
Co	Cobalt	0.05	Toxic to tomato plants at 0.1 mg l^{-1} in nutrient solution Tends to be inactivated by neutral and alkaline soils
Cr	Chromium	0.10	Not generally recognized as an essential growth element. Conservative limits recommended due to lack of knowledge on its toxicity to plants.
Cu[b]	Copper	0.20	Toxic to a number of plants at 0.1–1.0 mg l^{-1} in nutrient solutions
F	Fluoride	1	Inactivated by neutral and alkaline soils
Fe[b]	Iron	5	Not toxic to plants in aerated soils, but can contribute to soil acidification and loss of availability of essential phosphorus and molybdenum Overhead sprinkling may result in unsightly deposits on plants, equipments, and buildings
Li	Lithium	2.5	Tolerated by most crops up to 5 mg l^{-1}; mobile in soil. Toxic to citrus at low concentrations (<0.075 mg l^{-1}) Acts similarly to boron
Mn[b]	Manganese	0.20	Toxic to a number of crops at a few-tenths to a few mg l^{-1}, but usually only in acidic soils
Mo	Molybdenum	0.01	Not toxic to plants at normal concentrations in soil and water. Can be toxic to livestock if forage is grown in soils with high concentrations of available molybdenum
Ni	Nickel	0.20	Toxic to a number of plants at 0.5–1.0 mg l^{-1}; reduced toxicity at neutral or alkaline pH
Pd	Lead	5	Can inhibit plant cell growth at very high concentrations
Se	Selenium	0.02	Toxic to plants at concentrations as low as 0.025 mg l^{-1}, and toxic to livestock if forage is grown in soils with relatively high levels of added selenium. Essential element to animals, but in very low concentrations
V	Vanadium	0.10	Toxic to many plants at relatively low concentrations
Zn[b]	Zinc	2	Toxic to many plants at widely varying concentrations; reduced toxicity at pH >6 and in fine textured or organic soils

[a]The maximum concentration is based on a water application rate that is consistent with good irrigation practices (5000–10 000 m^3 ha^{-1} $year^{-1}$). If the water application rate greatly exceeds this, the maximum concentrations should be adjusted downward accordingly. No adjustment should be made for application rates less than 10 000 m^3 ha^{-1} $year^{-1}$. The values given are for water used on a continuous basis at one site.

[b]Synergistic action of Cu and Zn and antagonistic action of Fe and Mn have been reported in certain plant species' absorption and tolerance of metals after wastewater irrigation. If the irrigation water contains high concentrations of Cu and Zn, Cu concentrations in the tissue may increase greatly. In plants irrigated with water containing a high concentration of Mn, Mn uptake in the plants may increase, and, consequently, the concentration of Fe in the plant tissue may be reduced considerably. Generally, metal concentrations in plant tissue increase with concentrations in the irrigation water. Concentrations in the roots are usually higher than in the leaves.

that controls that are effective in one part of the world would necessarily be effective in another.

Environmental Aspects

The use of wastewater in agriculture has the potential for both positive and negative environmental impacts. With careful planning and management, the use of wastewater in agriculture can be beneficial to the environment.

Where wastewater treatment services are not provided, the use of wastewater in agriculture actually acts as a low-cost treatment method, taking advantage of the soil's capacity to naturally remove contamination. In addition, the nutrients contained in wastewater can offset or replace the need for chemical fertilizers that can damage the soil structure. Therefore, the use of wastewater in irrigation can help to reduce downstream health and environmental impacts that would otherwise result if the wastewater were discharged directly into surface water bodies.

However, there are potential negative environmental impacts of wastewater use such as soil salination and heavy metal contamination, and these vary according to the composition of the wastewater used and properties of the land used and

duration of the application of wastewater. Wastewaters with industrial effluents included are generally more harmful that domestic effluent.

Efforts should be made to reduce or eliminate practices that entail the mixing of industrial and domestic wastewater, particularly where wastewater is used for agriculture. Many environmental impacts can be reduced by good agricultural practices.

PUBLIC HEALTH MEASURES

Food Control and Public Health Laboratories

MFG Jermini, Cantonal Laboratory, Ticino, Switzerland

Introduction

The principal objectives of national food control systems are:

- Protecting public health by reducing the risk of foodborne illness;
- Protecting consumers from unsanitary, unwholesome, mislabeled, or adulterated food; and
- Contributing to economic development by maintaining consumer confidence in the food system and providing a sound regulatory foundation for domestic and international trade in food.

Food control systems should cover all food produced, processed, and marketed within the country, including imported food. Such systems should have a statutory basis and be mandatory in nature. Although the components and priorities of a food control system will vary from country to country, most systems will typically comprise the following components:

- Food law and regulations
- Food control management
- Inspection services
- Laboratory services: food monitoring and epidemiological data
- Information, education, communication, and training

An important element of a national food control system is its integration in a national food safety system so that links between food contamination and foodborne diseases can be established and analyzed. Access to reliable and current intelligence on the incidence of foodborne illness is critical. The laboratory facilities for this type of activity are generally situated outside the food control agencies. It is essential, however, that effective linkages are established between food control agencies and the overall public health system including epidemiologists and microbiologists as well as the food inspection services. In this way, information on foodborne diseases may be linked with inspection data such as degree of implementation of hazard analysis and critical control point (HACCP), results of analytical own-check programs, official food monitoring and surveillance data, and lead to appropriate risk-based food control policies. This information includes annual incidence trends, identification of susceptible population groups, identification of hazardous foods and economic sectors, identification of high-risk food businesses, identification and tracing of causes of foodborne diseases, and the development of early-warning systems for outbreaks and food contamination. Only in this way risk-based inspections and risk-based food control programs can be planned as stated in many national legislations. The European Union (EU) regulation 854/2004 states indeed that 'the nature and intensity of the official controls should be based on an assessment of public health risks, animal health and welfare, where appropriate, the type and throughput of the processes carried out, and the food business operator concerned.'

Therefore, the present contribution considers that the work of a public health food laboratory should not be dissociated from considerations regarding inspection services; they both are elements of the risk management section within the framework of the risk analysis process. The entities should indeed work in close collaboration, taking into consideration important interactions that should exist between them and other governmental bodies or societal institutions.

What is Public Health?

The United Nations' World Health Organization (WHO) defines health as 'a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity.' Public health is typically divided into epidemiology, biostatistics, and health services. Environmental (e.g., food, water, waste, and noise), social, behavioral, and occupational health are other important subfields. Public health is 'the science and art of preventing disease, prolonging life, and promoting health through the organized efforts and informed choices of society, organizations, public and private, communities, and individuals.'

Investing in state and territorial public health systems is a direct investment in the health and wellness of a nation's population. The goal of public health is to improve lives through the prevention and treatment of disease and foster a nation of healthy people who will help strengthen the economy by creating a more productive workforce and lessen the burden on medical costs by lowering the need for intensive treatment for chronic diseases.

Among others, this is achieved by the following strategies:

- Incorporating positive opportunities for health, including access to healthy food choices and protection of people from largely preventable factors – causes of death and disability – such as microbial agents, toxins, and contaminants;
- Developing and implementing national, state, and local policies using science-based evidence that promotes prevention and wellness.

Food and Health – The 'Farm-to-Fork Life Cycle Approach'

A comprehensive food and nutrition policy comprises three strategies: on nutrition, food safety, and food security (sustainable food supply). This framework provides a starting point to address the question of how to promote public health through food. The strategies are interrelated because the food supply influences both the safety and the composition of food. Usually a number of government departments or agencies are concerned about food, including health, agriculture, fisheries, trade, tourism, education, environment, planning, and finance.

A comprehensive and integrated approach 'from farm-to-fork' is therefore required to ensure effective food safety policy.

Although the predominant concern during the seventies and for most of the eighties related to the risks of chemical pollution of the environment and food chain (due to pesticides, ground water pollution by animal waste, natural toxins, and drug residues in food), the later period has seen zoonotic disease emergencies of global public health significance. In both developing and industrialized countries, where nutritional issues and/or chemical contamination are still of concern, microbial contamination of food and the emergence and reemergence of zoonotic diseases continues to be a major problem along with concerns caused by the rising antimicrobial resistance and its possible links with the use of antimicrobial agents in food-producing animals. Despite recent activities and initiatives, the incidence of some foodborne and zoonotic diseases continues to increase, and it is a consequence of the influence of different factors, often interrelated and complex. These factors include changes in:

- Food supply system (see Figure 1), resulting in mass production and distribution leading not only to opportunities for contamination but also to larger outbreaks; in intensive agriculture and animal husbandry practices leading to increased contamination of the raw foodstuffs, increased use of pesticides and veterinary drugs; in international trade and importation of potentially contaminated food and infected animals; in a longer food chain as a result of urbanization and globalization with greater opportunities for contamination, growth, and survival; in the rapid increase in the number of food service establishments where food handlers do not necessarily have any training in food hygiene.
- Health and demographic situation, including population growth; increase in the number of vulnerable people such as the elderly and immunocompromised individuals, malnourished persons; rapid urbanization and ruralization of cities, particularly in developing regions with poor infrastructures.
- Social situation, behavior, and lifestyle entailing increased consumption of food outside of home; closer association between animals and humans, for example, pet animals; increased travel and exposure to unsafe food; change in food preparation habits; poverty and lack of education; lack of time and strive to increase economic profit; lack of training and education of animal keepers and food handlers.
- Health systems and infrastructure meaning a decrease in resources with simultaneous increase in the number of businesses which require supervision, guidance, and control; weaknesses in the investigation and surveillance of zoonotic and foodborne diseases and monitoring contaminants leading to incapacity to evaluate impact of these diseases; cutting resources for preventive public health and veterinary program and privatization of veterinary services.
- Environmental conditions such as pollution; climatic conditions and its changes; and changes in microbial as well as ecological systems.

Nutritional challenges vary as we progress through the human life cycle. Good nutrition during the first few years (maternal nutrition, breastfeeding, and introduction of safe and adequate complementary food) pays dividends throughout

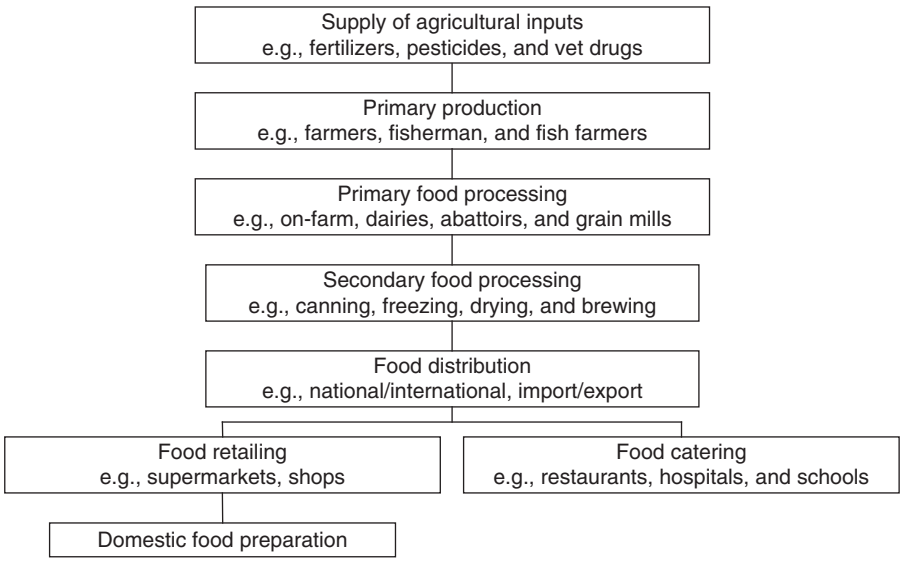

Figure 1 Principal stages of the food supply chain.

life. In adolescence, a period of rapid growth, the health impact of nutrition is pronounced. In adulthood, the main challenge is to avoid premature death from cardiovascular diseases and cancer. The issue of healthy ageing is also of major concern.

Contradictory opinions may be held by various parties involved; to be effective, food and nutrition policy will need to harmonize these opinions as far as possible. A 'farm-to-fork life cycle approach' taking into consideration food safety and nutritional aspects helps to find a consensus among potentially conflicting interests and strengthening partnership between sectors.

What is Food Control?

The terms food safety and food quality can sometimes be confusing. Food safety refers to all those hazards, whether chronic or acute, that may make food injurious to the health of the consumer. It is not negotiable. Quality includes all other attributes that influence a product's value to the consumer. This includes negative attributes such as spoilage, contamination with filth, discoloration, and off-odors and positive attributes such as the origin, color, flavor, texture, and processing method of food. This distinction between safety and quality has implications for public policy and influences the nature and content of the food control system most suited to meet predetermined national objectives.

Food control is defined as:

> ….a mandatory regulatory activity of enforcement by national or local authorities to provide consumer protection and ensure that all foods during production, handling, storage, processing, and distribution are safe, wholesome, and fit for human consumption; conform to safety and quality requirements; and are honestly and accurately labeled as prescribed by law.

The foremost responsibility of food control is to enforce the food law(s) protecting the consumer against unsafe, impure, and fraudulently presented food by prohibiting the sale of food not of the nature, substance, or quality demanded by the purchaser. It is again obvious that it would be inappropriate to dissociate analytical from inspectional food safety control activities.

Risk-Based Approach for Food Safety Control

Modern food safety control systems should include risk-based approaches in both testing and inspection.

As far as inspectional activities are concerned in identifying the level of risk, most of the systems presently in place in the EU have three levels, for example, high, medium, and low. Risk-analysis scores are used to determine classification of the establishment, which in turn determines the frequency of inspection or other controls. Allocation of responsibility for planning controls is often split between central planning and local application. Generic risk is normally determined at central level, based on inherent hazards, with a focus on the local level for targeting noncompliances. The approach of risk categorization might be very varied and there is no correct answer for risk categorization. A number of challenges have been identified:

- Ensuring an appropriate balance between risk to the consumers and political and economic risk.
- Identifying a cost-effective means of providing reasonable levels of assurance and increasing compliance distortion of categorization by media interest groups and political intervention.
- The system should be easy and not too costly in term of resources.
- The system should be documented.
- The system should be flexible to allow changes as necessary, especially for continuous improvement.

The EU Regulation 854/2004 states that the frequency of official controls should be regular and proportionate to the risk, taking into account the results of the checks carried out by feed and food business operators under HACCP-based control programs or quality assurance programs, where such programs are designed to meet requirements of feed and food law, animal health, and animal welfare rules. *Ad hoc* controls should be carried out in case of suspicion of noncompliance. Additionally, *ad hoc* controls could be carried out at any time, even where there is no suspicion of noncompliance.

As far as analytical activities are concerned, several elements are used to identify and rank food according to risk as well as to determine frequency of sampling and testing. Some national regulations lay down specific requirements for food sampling. In Germany, for example, these require 5 food samples and 0.5 samples of food commodities and cosmetics per 1000 people per year. Risk oriented sampling systems also consider food product risk, product compliance data over a defined period, business compliance over a defined period, and emerging risk and changing consumption patterns. In line with the farm-to-fork approach, sampling program also consider feed. In Austria, the population size, percentage of noncompliancy within different food types, and type of noncompliancy (leading to health problems related only to fraudulent activity, labeling, etc.) are used by the Central Authority, Agentur für Gesundheit und Ernährungssicherheit (AGES), to define type and number of samples which have to be taken officially by the different regions (Länder) of the country. In Ticino, Southern Switzerland, cantonal guidelines approved by the regional parliament laid down performance requirements for food control services of 1 food sample per 300 people per year and 1 water sample per 1000 people per year together with yearly inspections in minimum 25–33% of the registered business to be achieved by an overall expenditure of maximum 10 Swiss francs per habitant per year. Efficiency of the services are monitored by safety indicators related with the percentage of noncomplying inspected food businesses (should always decrease) and the incidence of foodborne diseases (appropriate level of protection) for *Salmonella* spp. and *Listeria monocytogenes*, which should be decreasing year after year and be below the national average.

Regulation 882/2004 of the EU requires each Member State to prepare a single integrated multiannual national control plan. This plan must contain general information on the structure and organization of the systems of feed

and food control and of animal health and animal welfare control in the Member State concerned among others on:

- The strategic objectives of the plan and on how the prioritization of controls and allocation of resources reflect these objectives;
- The risk categorization of the activities concerned;
- The designation of competent authorities and their tasks at central, regional, and local level, and on resources available to these authorities;
- The general organization and management of official controls at national, regional, and local level, including official controls in individual establishments;
- Control systems applied to different sectors, and coordination among the different services of competent authorities responsible for official controls in these sectors.

Similarly other nonEU countries have introduced multiannual programs, for example, Switzerland.

Organization of a Food Control Laboratory and Inspectorate

In many governmental structures there are staff and facilities located in different agencies that are involved in some or all aspects of food control, but their efforts are often not highly effective because of the lack of facilities, expertise, or an adequate legal or administrative framework. Food control laboratories and food inspectorates, as complementary elements within risk management, should be located within the same institution (ideally a public health institution) or alternatively have strong means for coordination.

Staffing of the Laboratory

Besides a head of the laboratory, analytical, administrative, and support staff should be active. The head of the laboratory may include a director and a deputy if the staff is sufficiently large. The head of the laboratory should be a graduate chemist or microbiologist trained in food safety. In some countries, conditions for assuming the position of a chief executive officer (or food inspector/ controller) within the food safety system are legally set; as a consequence, special university curricula to train official food safety officers are organized. Head of an official food control laboratory should receive a broad spectrum education including all food chemistry, microbiology and technology, elements of nutrition, food legislation at national as well as international level, food toxicology, strategies for risk-based food control, hygiene and HACCP, quality assurance, epidemiology, risk analysis (assessment, management, and communication), and elements of business and administration. Supervisors, or on-site managers of the laboratory, are also expected to be involved in analytical work; therefore, they also should be graduated in the specific area of work and have considerable experience in food analysis. A reasonable maximum number of analysts or lab technicians to be supervised by one person is 10–12. A team leader may also be appointed to do specific tasks or type of analysis. The main job of the analytical staff is to analyze the samples received. It can be drawn from three levels: university graduates, trained technicians, or unqualified staff who have received on-the-job training. The support staff of a laboratory are all those persons working in and for the laboratory who are not conducting analysis or are not involved in administrative duties. Some examples include washing, cleaning, and housekeeping. Laboratory administration includes staff responsible for sampling (if not assigned to official inspectorates), receiving and assignment of samples, storage and disposal of samples, budgeting, purchasing, supply management, equipment maintenance, housekeeping, training, and so on. Most of these activities, in line with the certification scheme ISO17025, are, however, assigned to scientific staff dealing with testing.

Analytical Activities

Normal activities of food control laboratories encompass tests on composition and residues of contaminants of different nature (chemical, microbiological, or radiological) using different techniques such as wet chemistry, titration, potentiometry, atomic absorption or emission, ionic, liquid, or gas chromatography, with different detection systems, gamma spectrometry, immunological tests, commercial rapid tests, and so on, for the chemistry and radiology or culture-based respectively, or molecular biological methods for microbiology. Accurate laboratory testing is essential to public health. Yet, no laboratory test can be guaranteed to be accurate 100 percent of the time. To assure that test results are acceptable and reliable, a laboratory must incorporate both quality assurance and quality control procedures into its daily laboratory routine. Laboratory design and features must be in line with the quality requirements set by international standards, such as the basic structure, safety features, ventilation and air conditioning, space utilization, and utilities.

Selection of the Contaminant-Commodities to be Investigated

Different strategies can be adopted to identify commodities and contaminant worthy of investigation. Ideally contaminants' choice should be related to epidemiological data; where data on foodborne diseases show high incidence of a particular pathogen among the population, and the frequency of sampling and testing of suitable commodities known to be potentially contaminated should be increased. Therefore, trend analysis of foodborne disease including typing patterns (e.g., different serotypes of *Salmonella enterica* sub. *enterica* or different biovars of *L. monocytogenes*) is essential to be able to identify and adopt correct risk-management options when dealing with important outbreaks or increased epidemiological figures. However, literature data or reports from other countries or international organizations such as WHO or Food and Agriculture Organization of the United Nations (FAO) regarding presence of pathogens or contaminants in certain food types should immediately foster specific testing at national or local level. The list of microbiological or chemical contaminants to be tested could be indeed drawn from trend

analysis from international alert systems such as the EU Rapid Alert System for Food and Feed or from other databanks such as the International Food Safety Authorities Network or from Food Global Environment Monitoring System – Food Contamination Monitoring and Assessment Program. Multiannual analytical programs from other countries, for example, for pesticide residues in the EU might also be suitable tools to identify appropriate commodities-contaminants to be investigated. In this context, analysis of food to assess compliance with nutritional composition standards should also be taken into consideration; content of vitamins or folic acid, presence or absence of allergens, fatty acid composition, and more should also be addressed within a national risk-based analytical plan.

Strategy and Aim of Sampling: The Link between Food Inspectors and the Food Laboratory

A sampling strategy means a planned procedure for selecting samples from a population and conducting the sampling to obtain the information needed. Terminology for selecting samples from a population is under development in EUROSTAT/Food Safety statistics. The competent authority should establish a sampling strategy. The following definitions for sampling strategies in the context of control and monitoring activities have been proposed by EUROSTAT:

- Objective sampling: A planned strategy based on the selection of a random sample, which is statistically representative of the population to be analyzed. Each unit, within the framework population, has a specified probability of being selected. This strategy provides data from which statistical inference can be implemented. It means that the results inferred are comparable. This approach could be applied to a convenient selection of food retailers for hygiene controls where the retailers are grouped according to predefined characteristics or a stratified regional selection of food producers for HACCP controls. It would give results that could be extended to all the population and breakdown by region. For example, sampling of soft cheese at the retail level for detection of *L. monocytogenes* to determine the prevalence in soft cheese at a specific point of the food chain or other monitoring schemes or surveys on the prevalence of foodborne pathogens in certain food categories.
- Selective sampling: A planned strategy where the selection of the sample is from previously defined 'high-risk' population groups. Samples are normally selected to either illustrate or document unsatisfactory conditions or suspected adulteration of a product. The sampling is deliberately biased and is directed at the particular products or manufacturers. For example, sampling of high-risk products, for instance, vacuum-packed cold-smoked fish product supporting the growth of *L. monocytogenes* during its shelf-life for detection and/or enumeration of *L. monocytogenes* to determine the rate of contamination and/or the level of contamination.
- Suspect sampling: A selection of samples where the units are selected on the basis of the judgment and experience regarding the population, lot, or sampling frame. The samples obtained from this procedure are not randomly extracted. For example, sampling carried out as a part of a foodborne-outbreak investigation or where an inspection indicates that there may be a food safety problem or where a HACCP plan review results in concerns regarding potential food safety problems.

The aim of sampling might be different, but usually sampling is carried out for monitoring and surveillance purpose as well as to assess food safety management plans. Monitoring is the performance of routine analysis aimed at detecting contamination of foodstuffs from which useful prevalence data may emerge. Surveillance is the performance of routine analysis aimed at detecting contamination of foodstuffs for the purpose of applying appropriate control measures. Such control measures are normally determined in advance. One of the main objectives of surveillance is to follow-up unsatisfactory results with an investigation and possible enforcement action. When assessing a food business operator's food safety management plan based on HACCP, good hygienic practices (GHP), and good manufacturing practice (GMP), the food inspector might find it necessary to take additional samples for official control if it has concerns about the food safety management systems or verification of the system. The extent of such official sampling is dependent on the food business operator's analyses' results and the competent authority's assessment of a food business operator's food safety management plans. However, the focus of the activities of the competent authority should be on both the assessment of the activities of the food business operator and on requesting them to correct their food safety management plans to ensure that the food business operator remedies weaknesses in their food safety control.

Staffing of the Inspectorates

Food control inspectorates should also be managed under quality control schemes, in particular ISO17020 (quality assurance scheme for inspection bodies). Food inspectors not only should possess a set of techniques and apply procedures to verify compliance with food safety and quality regulations, but also should foster food safety partnerships with food processors. This approach is derived from many experiences in countries where such partnerships have contributed greatly to the active involvement of inspectors in the improvement of existing quality and safety management systems. The approach requires a change of philosophy regarding the inspector's traditional regulatory role, which is generally limited to verifying that regulations are complied, to a vision of him or herself as a food safety professional actively contributing to improving the system through incremental changes that are meaningful with regard to enhancing the safety of food products. Thus, the philosophy relies on placing the inspector's emphasis on factors that are likely to lead to foodborne disease. The traditional regulatory inspection seeks only to obtain correction of food safety concerns that already exist rather than to prevent future violations from occurring. Although this approach may have helped to improve sanitation in the past, it emphasizes reactive rather than preventive measures. In contrast, the future should be on prioritizing inspections using a risk-based approach. This new approach

has proven effective in changing the attitude of the regulation to a new level of respect toward the inspector. In addition to a new philosophy and approach to food inspection, the focus should be replaced from the inspector's attention from environmental aspects and end-product testing to a risk-based process. That change of focus is from the simple (and often unfounded) 'verification' of the compliance of a product or premises with dated-prescribed regulations to an assessment of the controls put in place in the operation to address foodborne disease risk factors that could put the processor's products at risk (i.e., cause disease). Food inspectors should, therefore, have similar professional profile to the graduated staff working in the testing facilities, however, with a broad-documented experience in auditing techniques, especially in HACCP and GHP. Ability to confirm and verify whether or not the HACCP system of the inspected company is correctly working (all hazards identified, risk properly evaluated, CCP correctly defined and critical limits correctly set, monitoring procedures and corrective action in place, and verification and documentation implemented) are essential tools of a modern food inspector. Independency between inspectors and controlled institutions must also be granted to avoid conflicts of interest.

Inspectional Activities

The activities of a food inspector are mainly the following:

- Prepare for an inspection. If a full HACCP system is in place, then an audit (assessment/evaluation) should be performed. Preparation includes consulting the food control authority's records to gain an insight into the background of the operation to be inspected, its history of compliance and the product(s) it handles.
- Prepare a list of potential foodborne disease risk factors identified for the type of product and facility to be inspected.
- Prepare the necessary inspection wear (unless it is provided by the establishment), tools, and equipment.
- Make an adequate time allocation for the inspection based on the size and complexity of the operation.
- Obtain information about the registration status, the identification number of the facility, and, hopefully, the name(s) of the person(s) to communicate with before, during, and, if necessary for follow-up, after the inspection.
- Take care of personal aspects such as obtaining protective clothing (unless provided by the inspected establishment) and preparing the necessary equipment (e.g., flashlight, thermometer), sampling tools, note-taking materials, and official forms.
- Consider the task at hand and organize each inspection. Unless the inspection is a follow-up to a complaint or known violation, in which case a nonannounced visit is in order, establishments should be notified of inspections in advance so that management will be available to accompany the inspector during the inspection, and the necessary records will be available. The notion that this will result in preinspection-fixing of problems in the inspected establishment may be countered with the argument that if the inspection serves to fix something that is wrong, it is worth it. After all, the sooner non-compliances and violations are corrected, the better.
- Plan an opening meeting to get to know the management, explain the objective and scope of the inspection and the procedure to be followed, go over the relevant regulations, review existing records, discuss the quality and safety management system, and ask pertinent questions.
- Evaluate paper work regarding prerequisite programs, HACCP system, traceability, and recall procedures.
- Walk-through should be done to assess hazards and the associated controls, to observe the performance of the members of staff and floor personnel, and to talk to them.
- Take GHP or HACCP verification samples.
- Carry out an exit meeting, where noncompliance findings and ways of improving food safety and quality in the future are discussed.
- Record the observations and document them as needed.
- Have management sign the original and keep a copy of the inspection form.
- File the original of the inspection form with the food control authority.
- File a copy of the inspection form in a 'pending' file if follow-up is necessary, and, if the case, conduct an unannounced visit to ensure corrective actions have been taken.

As far as the prerequisite plan is concerned, the inspection must cover all the following aspects:

1. Plant construction and equipment program, i.e., the physical characteristics of the facility;
2. Standard Operating Procedures, the established procedures for conducting specific processing operations;
3. Sanitary Standard Operating Procedures, the plant and equipment sanitation schedules and procedures;
4. Pest control program;
5. Management review, the training received by management and the knowledge that managers have about food safety;
6. Personnel hygiene;
7. Training program;
8. Customer complaints and handling;
9. Suppliers' specifications and control;
10. Record keeping.

If the facility follows the HACCP system and has a HACCP plan in place, it should be available to the inspector. If a HACCP is in place, an audit will be undertaken, not an inspection. The traceability and recall program comprises all the techniques and procedures in place at the facility to (a) maintain records of incoming materials, indicating date, lot number, supplier, carrier, amount and condition, and (b) implement a recall program that allows products to be traced to retail in case they need to be withdrawn from the marketplace. This requires coding of all products, keeping records of lot and/or batch numbers, and keeping distribution records.

To trace back activity and justify the quality of the performance delivered, documentation and record keeping should be in line with the internationally recognized quality norms ISO17020 for inspectional bodies and ISO17025 for testing facilities.

Food inspectors as well as supervisors of the analytical laboratories should deliver inspection and testing report with exhaustive conclusion in order to facilitate interpretation of data and further action by responsible managers.

Interactions between Food Control Services and Other Public Health Authorities, Other Governmental Bodies or Societal Institutions

An effective, integrated national food control system is essential to protect the health and safety of domestic consumers.

As depicted in Figure 2, effective food control systems should work in close contact with other elements of the public health system as well as with other important socio-economical elements of our society. In general:

Food control services, consisting of food microbiology, chemistry, and radioactivity laboratories as well as food inspectorates should be element of an important network of institutions and liaise – as risk-management instrument – with risk assessors and other risk managers at all level (national, regional, and local). They should

a. Provide data on food contamination to risk assessors for their exposure and dose-response assessment as well as technological parameters of food for risk management;
b. Provide data of inspectional noncompliance, especially on pre-requisite programs and HACCP systems, to risk managers to define risk-based analytical programs as well as inspection frequency;
c. Careful evaluation, based on local epidemiology and environmental patterns, of the tests to be carried out on specific commodities;

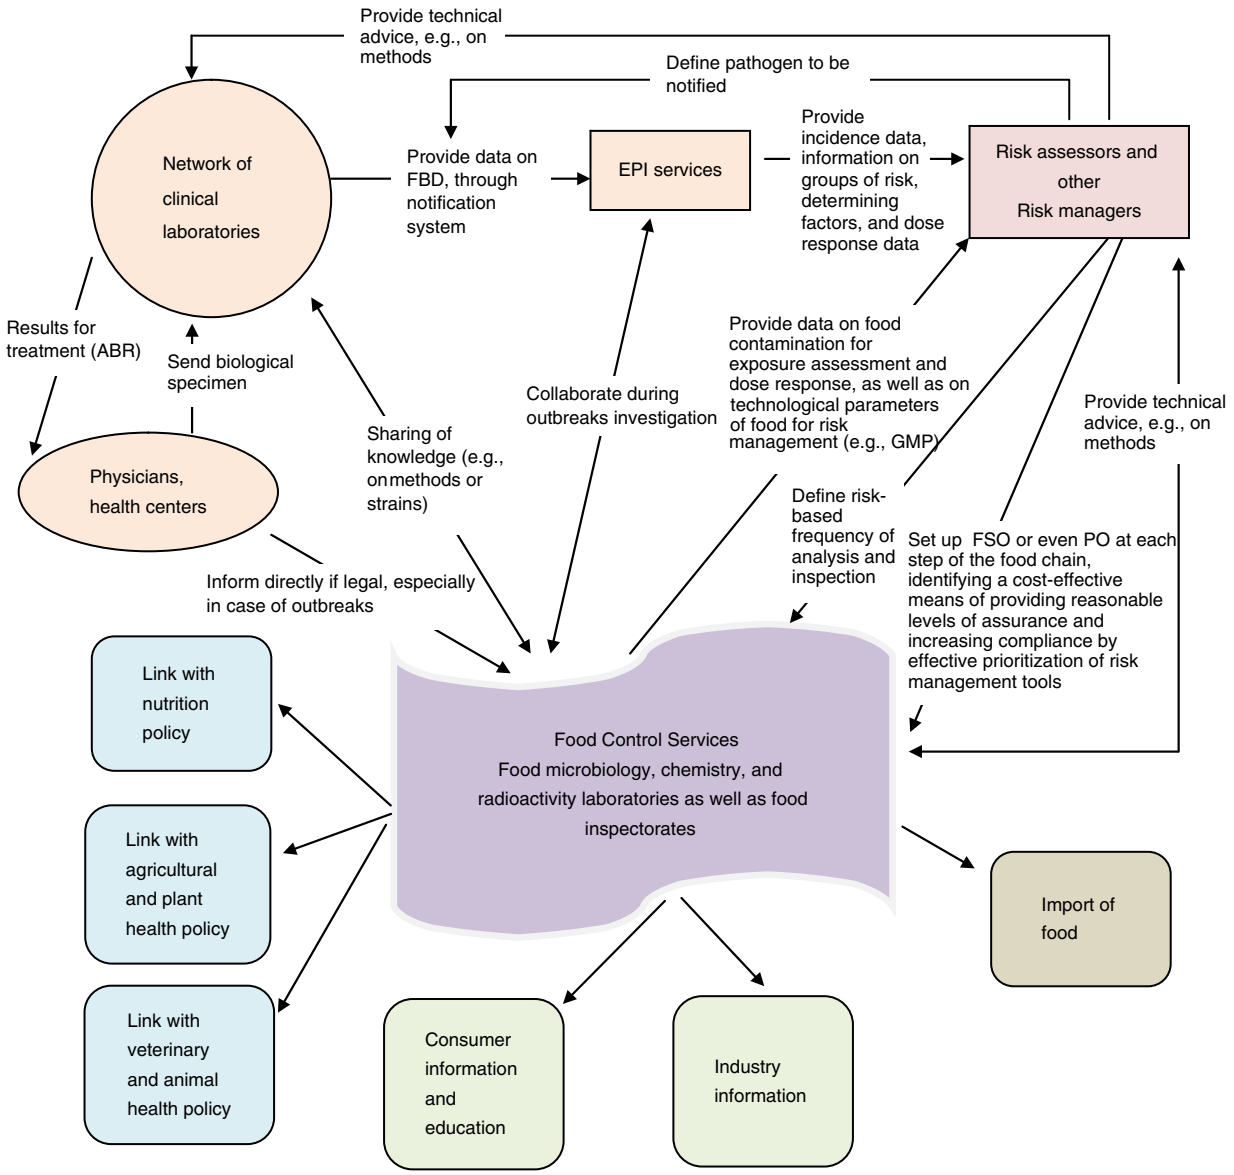

Figure 2 Interactions between food control and other public health authorities, other governmental bodies, or societal institutions.

d. Receive from risk managers (in principle from legislators) essential information on Food Safety Objectives in form of maximum residue limits or even Performance Objective for each step of the food chain, to be implemented as risk management tools;
e. Provide or receive, depending on their nature and capacity, important technical information or advice, for example, on analytical methods;
f. Liaise with custom services to provide adequate protection at importation level;
g. Interact with industry and other elements of the private sector to disseminate relevant information not only on legislation, but also on other risk-management tools such as sectorial GMP;
h. Keep in touch with consumer associations to disseminate relevant information necessary to implement food safety at home;
i. Communicate not only with the agricultural sector, thus primary producers, but also with the agricultural and economic institutions as well as veterinary services within the governmental administration to harmonize the approach and minimize conflicting situation between the economic and the health sector. Responsibility for food control in most countries is shared among different agencies. Further the roles and responsibilities of these agencies may be quite different and duplication of regulatory activity, fragmented surveillance, and a lack of coordination are common. There may also be wide variations in expertise and resources among the different agencies, and the responsibility for protecting public health may conflict with obligations to facilitate trade or develop an industry or sector;
j. Be in close contact with public health elements of the governmental administration dealing with nutrition in order to harmonize the approach and minimize conflicting situation between the safety and nutritional aspects of the food supply;
k. Work together with the physicians, epidemiological services, and network of clinical laboratories to collaborate during outbreak investigations as well as to share important information on agents and their antibiotic resistance, symptoms, methods of analysis and typing, patient patterns, data relevant for dose-response assessment, type of food involved and their technologically important parameters (such as pH, water activity, and redox potential), and so on. Close liaison must exist among food scientists and nutritionists, veterinarians, medical and other health professionals including epidemiology, surveillance, occupational health, and environmental control and laboratory services.

PUBLIC HEALTH MEASURES

Health Education, Information, and Risk Communication

Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland

Glossary

Case-control study Observational study in which subjects are enrolled based on the presence (cases) or absence (controls) of the disease of interest. Information is collected about earlier exposures and compared between cases and controls.

Fecal–oral transmission A means of spreading pathogenic microorganisms from feces produced by an infected host to another host, usually via the mouth, e.g. contact between contaminated hands or objects and the mouth.

Foodborne disease Any disease of an infectious or toxic nature caused by or thought to be caused by consumption of contaminated food, including drink. Frequently, the term food poisoning is used to mean foodborne disease. However, this use is misleading and is discouraged.

Foodborne pathogens Disease-causing microorganisms that are transmitted to humans via foods.

Food handler Any person who handles, prepares, or serves food, be they domestic food handlers, such as preparing family food, or professional food handlers, such as those working in food service establishments (cooks, waiters), retail stores, supermarkets, etc. (See also food worker.)

Food worker Individuals who harvest, process, prepare and serve food, i.e., across the whole food chain to retail/foodservice; it is a broader term than that of food handler, who typically works in foodservice establishments; however, the two terms are used interchangeably in the literature. (See also food handler.)

Outbreak A group of at least two cases of a single illness that are demonstrated by epidemiological investigation to have a single common exposure or source.

Introduction

There is no better introduction to such an article than the visionary speech of President John F. Kennedy, who in 1982 introduced The Consumer Bill of Rights, inscribing four rights:

1. The Right to Safety.
2. The Right to Be Informed.
3. The Right to Choose.
4. The Right to Be Heard.

Later, in 1985, the concept of consumer rights was endorsed by the United Nations through the United Nations Guidelines for Consumer Protection, which expanded these rights to eight basic rights, among which is The Right to Consumer Education.

The Consumer Bill of Rights was the forgoer of developments in food safety, which started in the 1980s, i.e., the recognition of

1. the importance of food safety,
2. the role of health education and consumer information, and
3. risk communication as an integral part of risk analysis, which in itself was to become the new approach to the decision-making process and management of food safety at national level.

From the above, it is clear that education and information of consumers in food safety or, more generally speaking, health education of consumers and risk communication are key responsibilities for any government. This should, however, not undermine the fact that other sectors such as academia and industry also have a role to play. For instance, through clear and validated labeling, industry is responsible for providing consumers with safety information, for example, declaration of food allergens, instructions on safe preparation or storage conditions, appropriate age or conditions of consumption, and/or any other safety warnings. However, the focus of this article is on the education and information of consumers as a governmental activity.

Health education in food safety goes beyond the simple exchange of information or communication of risks, although these constitute an integral part of it. Education per se can have many meanings, but it is generally defined as the process of learning and acquiring information. It is carried for different purposes such as imparting or acquiring particular knowledge or skills for a profession, a university degree, or more generally for developing the power of reasoning and judgment.

For the purpose of this article, health education in food safety refers to a process where the educator is providing necessary knowledge to empower and motivate the subject to a change of behavior, to adopting hygienic practice and/or making an informed and reasoned choice.

Education is also to be differentiated from training. Training is the process of teaching a person (or an animal) a particular skill or type of behavior, whereas education in food safety aims at influencing the way of life and empowering people to make

a reasonable and informed choice without imposing preconceived values. A key difference between training and education is that in training, the subject may learn to practice a behavior without knowing the reason or the science behind it. In education, the subject receives the knowledge and motivations to make informed decisions and choices.

The subjects of risk communication and crisis communication are addressed in other articles. Here, the subject of risk communication is addressed as it relates to health education and information.

Despite many international policies calling for increased education in food safety, and laudable efforts made during the past decades, in most countries of the world, the subject of health education in food safety has still not received the attention that it deserves, and a systematic education in food safety is yet to be established in the national public health and educational programs. For instance, to date, in spite of news on alarming outbreaks, few countries have introduced food safety in the curricula of their school health programs. Therefore, at the start of this article, it is important to write on the importance of the subject.

Importance of Health Education and Information

Although safety of food has probably been a cause of concern since the beginning of the existence of human beings, and foodborne diseases, be they microbial or intoxication, have prevailed since the dawn of history of humankind, it was in the mid 1980s that the subject of 'foodborne diseases' and its corollary 'food safety' have received increased and specific attention in public health.

A major milestone in the recent history of foodborne diseases was when a renowned group of experts of the World Health Organization recognized the gravity of the situation and in 1983 declared that "illness from contaminated food was perhaps the most widespread health problem in the contemporary world and an important cause of reduced economic productivity."

This declaration came at a time when several foodborne diseases such as salmonellosis and campylobacteriosis had started to increase, and new illnesses such as listeriosis and *Escherichia coli* O157 infections were emerging in the industrialized countries. Experience from these countries showed that with improvements in personal hygiene, safe water supply and basic sanitation, and the application of food technologies, such as pasteurization, a number of foodborne diseases, for example, shigellosis, typhoid and paratyphoid fevers, cholera, or brucellosis had decreased or been effectively prevented. Nevertheless, in spite of their extensive food control system (including legislation and enforcement mechanisms), industrialized countries continued to experience an impressive number of episodes of foodborne illnesses and these too encountered a major public health problem.

For instance, even to date, data from the US show that of the 178 million estimated acute gastroenteritis occurring each year in the USA, 48 million (27%) are believed to be foodborne in origin, resulting in 128 000 hospitalizations and 3000 deaths. This percentage is consistent with that found by a similar type of estimate made in the Netherlands, where 30% of the 1.8 million gastroenteritis cases are probably foodborne.

Additionally, an analysis of reported foodborne disease incidents and outbreaks in these countries has shown that a great proportion of these illnesses occur as a result of faulty handling of food during preparation and storage in homes or in food service establishments. Not undermining the fact that raw agricultural products can also be contaminated and are partly a source of these outbreaks; domestic or professional food handlers could render food safe, or prevent their contamination, if they are better educated in food safety (see Section Methods and Approaches for Selecting Key Behaviors) for the predominant errors in food handling that lead to foodborne illnesses.

From the experience of industrialized countries, it is very clear that a regulatory system, no matter how comprehensive it may be, cannot alone prevent the occurrence of foodborne illnesses.

Experience from industrialized countries has shown that when regulatory and educational measures have been combined, the measures have been effective in reducing foodborne diseases. A case in point is the measures taken in the UK and the USA to prevent listeriosis. Combined regulatory and educational measures have been successful in significantly reducing the incidence of this disease.

In developing countries, where foodborne illnesses are more widespread, the situation is alarming. These countries are affected by a range of foodborne illnesses: amebiasis, brucellosis, cholera, campylobacteriosis, *E. coli* gastroenteritis, poliomyelitis, and salmonellosis are only a few examples. With poor or nonexistent reporting systems in most countries, reliable statistics on these diseases are not available and their magnitude is, therefore, difficult to estimate. The gravity of the situation can, however, be appreciated by the high prevalence of diarrheal diseases, particularly in infants and children. Globally, some 1.3–1.5 million deaths of children aged less than five, i.e., nearly one in five child deaths is associated with diarrhea. Although this is a remarkable decrease from the 4.6 million of the 1980s, diarrheal diseases remain the second leading cause of death in children, after respiratory diseases. According to the 2004 estimates, an estimated 4.6 billion episodes of diarrhea occur worldwide per year for all ages and 2.2 million die as a result.

In spite of the reduced mortality, the morbidity has not declined in the past 30 years. In the developing regions of the world, on average, children less than the age of five continue to suffer 3.2 episodes of diarrhea per year. In a great proportion of these cases – possibly up to 70% – these are due to contaminated food and water used for drinking or for preparation of food. A plethora of pathogens, i.e., bacteria, viruses, and parasites are associated with infectious diarrhea. These include: pathogenic *E. coli*, *Shigella* spp., *Salmonella* spp., *Vibrio cholerae*, *Campylobacter*; protozoa such as *Giardia lamblia*, *Entamoeba histolytica*, *Cryptosporidium* spp.; and viruses such as rotavirus. In this context, it is to be noted that infections with *E. coli* are probably the most common cause of diarrhea in developing countries. The frequent contamination of foods with *E. coli* and pathogens of fecal origin signifies the contamination of food with fecal matters. Consequently, any pathogen that can be transmitted through the fecal–oral transmission of pathogens

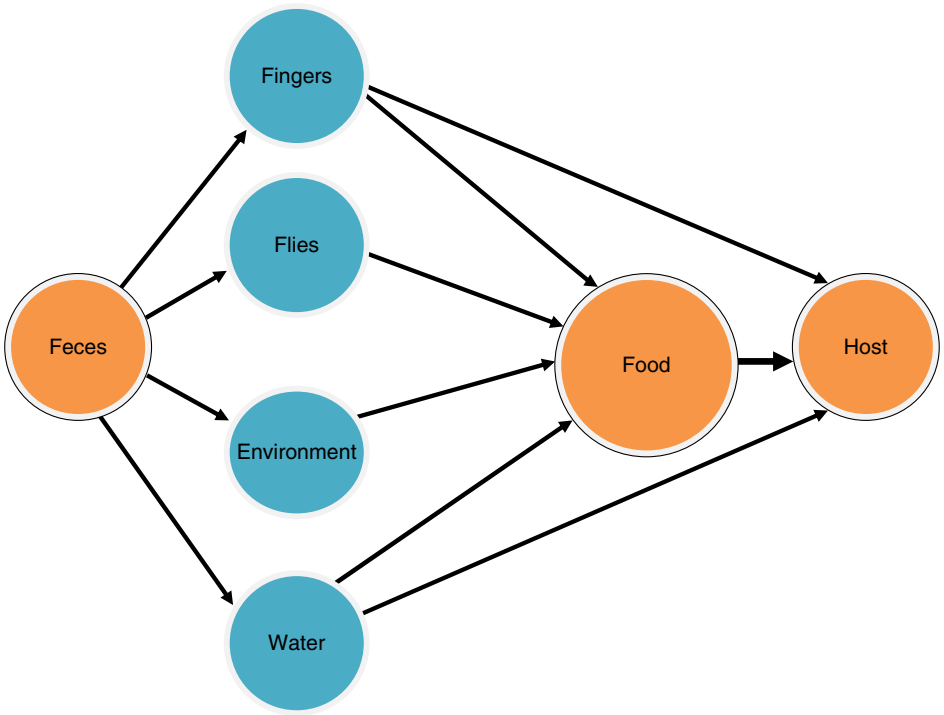

Figure 1 Role of food in the fecal–oral transmission of pathogens.

can be transmitted through food. The role of food in the fecal–oral transmission of pathogens is shown in Figure 1. Therefore, in developing countries, where subsistence farming and agriculture is more prevalent and food production and/or preparation are even less industrialized, education of the population in food safety, or guidance on how they should manage food safety risks in a contaminated environment, becomes even more important. Poverty, rudimentary sanitary conditions, and lack of food preparation facilities in the poorest countries are all aggravating factors and urge for a nonregulatory approach to food safety.

Over and above health aspects, education in food safety is also important because it contributes to the reduction of health care costs, as the cost of foodborne illnesses and their sequelae can by itself be a significant source of economic loss. An improved food safety situation also promotes trade and tourism, which are all contributing factors to prosperity and economic development.

There are also other reasons for which education in food safety should receive particular attention.

As alluded above, preparation is the last stage of the food chain before consumption and hence it is a critical control point (CCP) of the food chain. In this last stage, any foodborne pathogens that may have contaminated food at an earlier stage or during food preparation itself, or have found conditions favorable for growth to disease-causing levels, if not inhibited at this stage, are likely to cause infection in the target host. Also, as a result of urbanization, the food chain has become longer and more complex; thus, opportunities for contamination or growth of microorganisms are increased. Additionally, mass production has contributed to the spread of infections among food animals and contamination of derived foodstuff. All these factors underline the increasing role of food handlers and consumers and the importance of their awareness and compliance with good hygienic practices.

Certain groups of the population are subject to a greater risk of contracting foodborne infections and intoxication than others. These people need to be educated to protect themselves. Two high-risk groups can be distinguished:

1. Travelers, because they are more likely to be exposed to contaminated food and lack immunity to the microbiological flora of the country they visit.
2. Vulnerable people, because, for physiological or other reasons, they are more susceptible to foodborne infections. They include: infants and children, the elderly, pregnant women, persons who are undernourished, those with underlying illness, for example, liver disease or diabetes, and those who are immunocompromised due to an infection, for example, acquired immunodeficiency syndrome (AIDS), the malignancy of their disease, or their immunosuppressive treatment. Poor health and nutritional status caused by war, famine, and natural disasters make the population more vulnerable. In these latter conditions, the risk of epidemics is greater. Thus, all the populations more vulnerable to foodborne illnesses should be educated to protect themselves.

Tourism, migration, as well as international trade in food also lead to change in the dietary habits and expose the population to foods and pathogens that may be new to them. For instance, an increased immigration in Denmark in the 1990s led to increased consumption of red kidney beans among the local population. As the indigenous population was not familiar with the proper preparation of the beans, the

number of cases of intoxication due to hemagglutinin increased. Subsequently, the health authorities in Denmark launched a campaign to educate consumers in the proper cooking of various beans. Incidence of salmonellosis also increased in Japan after a change in dietary habits and increased consumption of foods of animal origin.

Advances of new food technologies in the society also justify the need for information and education of the population on the new technologies and the handling of the derived products. For instance, so often people think that a dried product is sterile as they can store the product at room temperature without it spoiling. A case in point is infant formula that after its reconstitution and storage at ambient temperature led to various illnesses in infants, such as salmonellosis and *Cronobacter* infection (previously referred to as *Enterobacter sakazakii*). Also, frozen prepared meals improperly warmed in microwaves have led to outbreaks.

Finally, consumers can make an informed decision which is right for them only if they are properly informed of the risks and benefits of the foods they eat and of the technologies that are used for their production or processing.

Frequently, the question is raised about the evidence for the efficacy of education for the prevention of foodborne diseases, in particular foodborne diarrhea. The problem in answering this type of request is that often education alone is not sufficient to prevent foodborne illnesses and as mentioned above about listeriosis, a combination of efforts is necessary. Also, when foodborne illnesses are prevented and an adverse event does not occur, it is still not possible to attribute the outcome to the efficacy of a specific preventive measure. Nevertheless, there are some studies and report which provide evidence for the positive impact of training and education in food safety. A case is the report of Seville Expo in 1992, where reportedly a 15 h accredited training course of some 8000 food handlers (including reserve staff) before opening of the Expo was effective in providing safe meals and foods for the visitors. Similar initiative were taken in case of 2010 International Federation of Association Football World Cup in South Africa. However, an experience from Latin America provides an insight to factors which may negatively influence the outcome of an educational and training activity. During 1995–96, the Pan American Health Organization conducted a study to evaluate the microbial contamination of street food sold in eight Latin American cities. Over and above the fact that a significant proportion of the foods were contaminated, it was also found that much of the effort made in training of street food vendors did not produce significant changes in the contamination of the foods prepared by them. Most of the hygienic procedures taught to food handlers, like hand washing, using dispensable utensils, clean clothing, etc. created additional costing that ultimately impacted on the price for consumers. Because consumers were not educated to appreciate the importance of improved hygiene, they preferred food with lower price. Subsequently, the discouraged street food vendors returned to their old habits.

Selection of Key Behaviors

Experience from the various fields of health has shown that change of behavior in the population, in particular the adult population, is often very difficult. Therefore, it is necessary to focus the educational program on a selected number of behaviors that are likely to have the highest impact on health and effectively prevent foodborne diseases. These behaviors are referred to here as key behaviors.

The selection of such behaviors is a fundamental question in any health education program. As opposed to some other areas of health where one hazard or behavior is targeted, such as the prevention of tobacco, the selection of key behaviors in food safety is particularly complex. These reasons are:

1. Education in food safety is aimed at preventing a wide range of diseases caused by totally different etiological agents: bacteria, viruses, parasites, naturally occurring toxins, and other hazardous chemical agents and antinutritional factors.
2. The etiological agents differ considerably in their behavior and ecology. Some, like most bacteria, grow on food, whereas others such as viruses and parasites do not. Bacteria alone show a wealth of variation. The range of temperature for bacterial growth varies widely. Some agents such as salmonellae are mesophilic and their growth is slowed down or stopped at refrigeration temperatures (below 10 °C); others such as *Listeria monocytogenes* or *Yersinia enterocolitica* can grow at these temperatures. Although, most parasites are killed by thorough freezing (-18 °C for at least 24 h), bacteria and viruses survive. Some agents like *V. cholerae* are sensitive to acids and may not survive an acidic food environment or even gastric acid, whereas others such as *E. coli* O 157 are acid resistant. Some bacteria grow or produce toxin only under anaerobic conditions, whereas others require oxygen. Some bacteria are hazardous if ingested (e.g., *Campylobacter*), whereas others are hazardous only if they have the opportunity to produce toxins in food (*Clostridium botulinum*). The toxin of some bacteria (*C. botulinum*) is thermolabile and is destroyed by adequate heating, whereas the toxin of some others (e.g., *Staphylococcus aureus*) is heat resistant. There may be variations even within one species. For instance, depending on the type of strain (diarrheal or emetic), *Bacillus cereus* may produce heat-labile or heat-stable toxins.
3. Food preparation is a complex procedure that involves a multitude of actions, some influenced by socioeconomic conditions or cultural habits. Not only the actions themselves may be hazardous (e.g. undercooking, storing food at room temperature, and touching with contaminated hands) but also the order in which they are carried out may constitute a risk factor.
4. The likelihood of contamination, i.e., the risk that a certain food or behavior will cause disease varies according to environmental conditions and source of food. For instance, manure or wastewater may present a health hazard, but if vegetables are grown according to good agriculture practice, they are generally safe. In times of algal bloom or red tide, in the sea, the consumption of shellfish or some species of fish may present greater health risk than that in normal circumstances. Thus, the type of food or method of preparation may be safer at one time or in one area, but unsafe at other times or in other environmental conditions.

5. The infective or toxic dose varies according to pathogens, toxic substances, individuals, and the food matrix. Some pathogens, such as *Shigella* spp., have a low infective dose, and even a few cells can cause disease. Others such as salmonellae may require a large number of cells to cause infection, and healthy adults are at risk only if the food is grossly contaminated or has been subject to time/temperature abuse. Even pathogens with a generally high infective dose may sometimes present a danger to health in low numbers if the composition or structure of the food is likely to protect from gastric acid. For example, some *Salmonella* serotypes in a chocolate matrix have been found to be infective at a low number, possibly due to the protective effect of the lipid component.
6. The risk posed by foodborne diseases is not the same for all individuals. Certain individuals are more vulnerable to some pathogens than other individuals are. Thus, a food or behavior may constitute a risk factor for one person but not for another. In addition, some persons may have allergic reactions to some foods or to ingredients, whereas others are not affected.
7. The likelihood of an adverse food safety event is related not only to the above factors but also to a range of other factors that find their root in the socioeconomical cultural conditions.

Therefore, for an effective health education intervention that requires a considerable amount of resources, time, and energy to be successful, it is important to:

1. base the health education intervention on the changes of behavior which have proven to lead to illness or are of relevance to food safety and
2. consider the sociocultural and economic factors underlying the risky behavior.

Methods and Approaches for Selecting Key Behaviors

Depending on the situation and nature of hazards, different methods can be used.

Toxicological or Epidemiological Evidence of Hazards Inherent in Certain Foods

Toxicological or epidemiological studies can provide evidence of hazards associated with certain foods, such as toxicants in mushrooms or wild green plants, marine biotoxins in fishery products, and hemagglutinin (lectin) in red kidney beans.

Monitoring Contaminants

It is a prospective approach in which information on the extent and level of hazardous contaminants and their health risk is obtained through monitoring of foodstuffs. Information collected can be used for regulatory action or education of the population. For instance, results of monitoring of methylmercury in fish have led some countries to advise pregnant women to limit consumption of some species of fish in order to keep the dietary intake of methylmercury within safe levels. In times of disasters (e.g., Chernobyl and Fukushima nuclear disasters), monitoring data have been used to advise the population to restrict consumption of affected foods.

Foodborne Disease Outbreaks and Epidemiological Investigation and Surveillance

Surveillance of investigated foodborne disease outbreaks and the root cause analysis of outbreaks provide information on major illnesses and their trend, the principal factors (mishandling) leading to foodborne diseases, places where food is likely to be contaminated, and the type of food frequently implicated. For instance, reviews of foodborne disease outbreaks in several countries have shown that major risk factors for salmonellosis and *S. aureus* intoxication is time/temperature abuses, whereas for shigellosis and typhoid fever it is the handling of food by an infected food handler.

The limitation of this approach is that in most countries, particularly in developing countries, the infrastructure and trained personnel for investigation of foodborne disease outbreaks are poor or nonexistent. Also, usually only outbreaks involving large numbers of people are investigated. Thus, statistics may not adequately reflect the incorrect handling leading to sporadic cases of foodborne diseases.

Worldwide investigation of outbreaks have shown that factors that are the predominant cause of foodborne disease outbreaks and should be the subject of health education measures are:

1. preparation of food several hours before consumption, combined with storage at a temperature that favors growth of pathogenic bacteria and/or formation of toxins;
2. insufficient cooking or reheating of food to reduce or eliminate pathogens;
3. use of contaminated water or raw food material;
4. cross-contamination in the premises where food is prepared; and
5. infected or colonized persons in charge of the preparation of the meals.

Case-Control Studies of Sporadic Cases

Epidemiological case control of studies of sporadic cases is widely used to study risk factors and thus identify behaviors that need to be changed or promoted. Case-control studies can be simple and economical to carry out. However, the validity of the factors identified and the success in targeting the relevant risk factors depend very much on the design of the study. As the studies become more comprehensive, the validity of the results improves, but so do the expenses and the complexity of the study. Unfortunately, many studies omit factors related to food safety or do not reflect them properly. As a result, conclusions may be misleading. For instance, for the prevention of diarrheal diseases, scientists have investigated the impact of toys, baby bottles, and dirty diapers strangely without even questioning the role of food contamination.

The Hazard Analysis and CCP (HACCP) System

The HACCP system is a scientific method for food safety assurance. It consists of a systematic identification and assessment of hazards and the determination of effective control measures and monitoring of those that are critical for safety. The steps identified as critical are referred to as CCPs and are the key behavior that should be the target of educational interventions.

The system was originally developed for ensuring the safety of foods for astronauts. Today, it is applied worldwide, across the entire food chain from primary production, processing, and manufacturing to final preparation and consumption of foods. It is intended to focus the attention, efforts, and resources on the measures critical for the safety of food. The full system as applied in the food industry has seven principles, including documentation and record keeping. In health education in food safety, the HACCP system has two applications. First, the system can be used as training of professional food handlers. In this case, food handlers are taught to think along the first five principles of the HACCP system, i.e., to evaluate the potential risks with their raw materials and operations and how to use the various control measures (cooking, refrigeration, washing, etc.) to manage the safety of prepared foods.

The second is the application of the system for analyzing the food preparation practices in homes, street food vending operations, cottage industry, etc., and for identifying the steps and practices that are critical for safety or are CCPs. As mentioned above, these are the 'key behavior' which should be subject of educational interventions. The application of the HACCP system has been particularly important for the education of caregivers in the preparation of infant food or of street food vendors. Another application, outside of the scope of this article, is in the training of food inspectors so that they focus their attention, in priority, on CCPs of the food operations and confirm that these points are well managed.

In this context, it is to be noted that the risks at each step of food preparation, i.e., the decision whether the step is critical for safety or not depend on the general hygienic conditions and an accurate evaluation of these. In other words, the focus on critical steps should not undermine the importance of underlying hygienic conditions that are a premise for the validity of the hazard analysis.

Factors Influencing Behavior

In relation to food safety, behavior is influenced by a number of cultural, socioeconomic, and environmental factors. Experience has repeatedly demonstrated that knowledge of risks alone will not bring a change in behavior. There are cases where people will adopt risky practices or eat a risky food, knowing the dangers that are involved.

There may be different reasons for this; for instance, it may be due to their perception of the risk and their acceptability of the risk, their bias and overoptimism about the likelihood of occurrence of the illness, or the severity of it. There may also be economical or social reasons. Therefore, social scientists have classified the conditions necessary to change behavior into three groups:

1. Predisposing factors: These are the antecedents to the behavior that motivate or provide the person with the rationale to change behavior. Knowledge of food safety hazards and their risks for health are among these. Other such factors are beliefs, values, attitudes, confidence, and existing skills.
2. Enabling factors: These are the conditions in the environment that enable the motivation to be realized. Examples of enabling factors are availability or accessibility to facilities for food preparation (e.g., easy access to water and facilities for hand washing, means for cooking, or refrigeration) and supporting policies (e.g., legal framework such as paid sick leave for professional food handlers or maternity leave enabling mothers to breast feed and care for their children).
3. Reinforcing factors: These are the factors that follow the behavior. They provide the continuing reward or incentive for the behavior and contribute to its persistence and/or repetition. Among the reinforcing factors is the reward or approbation of parents, a teacher, or the manager in the case of a food service establishment for hygienic practices or reprimand by them in case of poor practices. Peer pressure is also an important reinforcing factor that can encourage the individual to adopt certain positive or negative behavior.

Therefore, over and above identifying the factors that lead to illness from a pure scientific perspective, it is important to also understand the underlying factors that motivate individuals to adopt or reject good practices, in particular their perception of risk and their belief, and build the education program accordingly. **Box 1** presents examples of risk perception of people or professionals on food safety or on the causes of foodborne illness. These lead to errors in their practices or influence their acceptance of risk.

To better understand these social and cultural factors, sociologists have different methods such as Knowledge,

Box 1 Common misconceptions in food safety, among both general public and health professionals

1. An unsafe food will look, smell, or taste bad
2. What is visibly clean is safe (free from bacteria)
3. Cooked food can be stored at ambient temperature for extended time as the bacteria are killed
4. A dried food, for example, powdered milk and infant formula, is sterile
5. Warming or cooking food is for improving palatability and digestibility (its importance for safety is often overlooked)
6. Food additives are a health hazard
7. Food irradiation makes food radioactive
8. Unprocessed foods are generally safer
9. Diarrhea is a benign and self-limiting health problem with no long-term health impact
10. Contamination with a few bacteria has no major health consequence, ignoring some bacteria have a low infective dose
11. Diarrhea is caused by imbalance of heat and cold associated with food (general public)
12. Diarrheal illnesses are mainly waterborne (health professionals)
13. Outbreak data represent the magnitude of foodborne diseases (health professionals)
14. Microbial safety of products can be prevented by testing
15. All hazardous chemicals in food present a risk
16. Naturally occurring chemicals are not hazardous

Attitude, and Practice studies; surveys; focus groups; or root cause analysis in case of an incident.

Implementation of Health Education in Food Safety: Strategy, Plan of Action, and Evaluation

Target Audience

In principle, health education in food safety should target almost the entire population from the policy makers to food producers, food processors, professional food handlers, and consumers, as all have a role in food safety and all are also potential food handlers. However, for the purpose of this article, the target groups considered here are specifically those who have a direct and key role in food preparation, such as professional food handlers or consumers, or those that, due to their susceptibility (e.g. elderly, pregnant women), need to receive a greater emphasis in the health education programmes. These include:

1. Domestic food handlers, particularly mothers of small children.
2. Professional food handlers including those who handle, prepare, and serve food in cottage industries, food and catering establishments, retail outlets, supermarkets, and street food vendors.
3. High-risk groups, including travelers.

Partners

Governments, in particular the health sector, have the leading role in health education in food safety. They are responsible for initiating, coordinating, and implementing food safety educational programs and related measures. However, the impact of their effort is strengthened if the educational program is developed and implemented in partnership and collaboration with other sectors or community groups. Examples of partners who are in a position to influence food handlers are presented in Table 1.

Plan of Action

Problems, sociocultural features of the population, and available resources vary from country to country. It is, therefore, not possible to devise a plan of action or provide a curriculum for a food safety education program that would be globally applicable. Each country or region should develop a plan of action that is relevant to its needs, population characteristics, and infrastructure.

However, here few recommendations are given on the subject. They are valid for educational programs, whether they are applied at national level are more specific or limited in scope or time (Figure 2).

Recognition, Commitment, and Resources

Political recognition and endorsement of the aims and objectives of a food safety education and support from prominent community leaders and institutions are essential to the success of a program. Thus, the first steps toward health education in food safety are to raise the awareness of policy makers on the importance of foodborne disease and the role of health education in food safety, ascertaining commitment for integrating education in food safety into national food, nutrition, and related public health policies. Resources for the implementation of the program also need to be identified and made available.

Coordination

Education in food safety has a greater chance of success if all concerned sectors are appropriately involved. The public health sector has the leading and coordinating role. However,

Table 1 Partners in education in food safety by target population, as applicable to the system of the country

Partners for implementation	*Target population*
Public health services, primary health care centers, clinics, hospitals, and physicians	Parents of small children High-risk groups (elderly, children, immunocompromised individuals, pregnant women, and travelers) and general public
Maternal and child health centers	Pregnant or lactating mothers of infants and young children
Academia (universities and research institutes)	Food workers, public health professionals, food scientists, food inspectors, and policy makers
Secondary and primary schools	Children and adolescents, teachers, and parents
Professional schools	Professional food handlers (cooks and waiters/waitresses) and managers of hotels and restaurants
Food industry, including food service and catering establishments	Professional food handlers or food workers, supermarkets, retailers, and consumers
Supermarkets and retailers	Professional and domestic food handlers
Mass media	Policy makers and the general public
Food inspectors (consumer affair bureau)	Consumers, food industry, food service and catering establishments, and street food vendors
Consumer groups	Consumers and policy makers
Religious and social institutions	Consumers, particularly those disadvantaged
Tourism sector (travel agencies and tour operators)	Travelers and hotel management personnel
Local police and municipalities	Street food vendors, retailers, and food service establishments

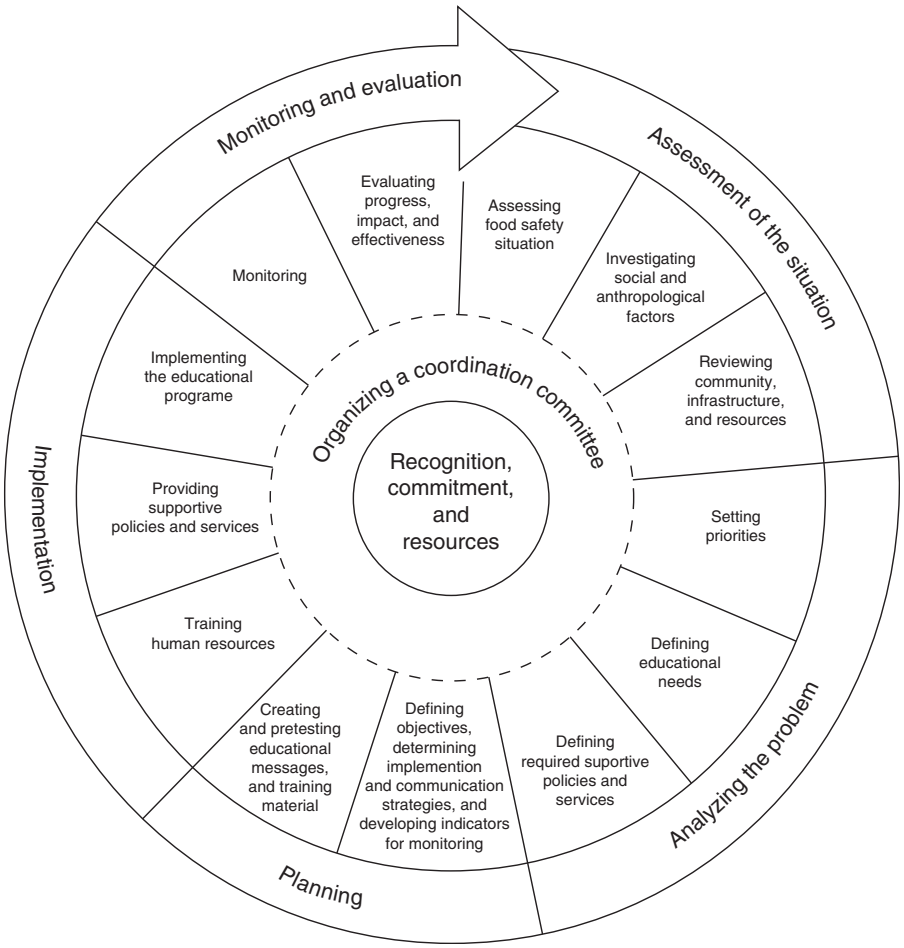

Figure 2 Key elements of a plan for health education in food safety.

through an interdisciplinary committee, or a similar mechanism, it must also involve representatives of other sectors, be they governmental or nongovernmental (e.g., universities, research, and consumer groups).

Assessment of the Situation

Health education in food safety should be culture specific. It must respond to the health, technological, social, and economical situation that prevails in a particular society or in particular cultural or social groups. The educational program or interventions should take into account problems and needs that are specific to the target groups. As mentioned before, it should be based on a combination of two types of information: (1) technical information on food safety and practices that leads to foodborne illnesses and (2) underlying social and economic factors that influence food safety. It should also take into account available resources and the characteristics of the target population. The latter will influence the strategy and partners for implementing the program.

Where such data are not available, research studies may need to be initiated before planning and implementing the program. Universities and other health and educational institutes can facilitate this kind of study. The assessment of the situation and the identification of the problems would also require an interdisciplinary team including epidemiologists, food scientists, and anthropologists.

Analysis of Problems and Decision Making

The results of the assessment should lead to the analysis and identification of problems and priorities, selecting appropriate strategies, defining educational needs, and decisions on the supportive policies and services.

Planning and Implementation

Following the identification of problems and educational needs, a plan should be developed. The plan should specify priorities, define objectives, and determine strategies for communication and for the training and education of various target groups or population groups. The plan should determine the need for qualified and trained human resources, supportive policies, and other services as well as the means to achieve them.

The selection of strategies and partners for implementation should take into consideration the characteristics of the population and the existing infrastructure. As part of the planning and implementation process, training material or educational messages need to be developed for the different

Table 2 Criteria for evaluating food safety education programs

Criterion	*Definition*	*Example of application*
Effectiveness	The degree of attainment of predetermined objectives	Have food handlers' practices improved? Have the levels of knowledge increased and behavior changed? What percentage of food handlers has adopted the desired behavior?
Impact	The overall effect on health and related socioeconomic development	What is the overall effect on health and related socioeconomic development? Has there been a decrease in foodborne diseases or related economic costs?
Efficiency	The relationship between the results obtained and resources spent	What is the relationship between the results obtained (decrease in incidence of foodborne diseases or number of food handlers trained) and resources spent?
Progress	The comparison of actual with scheduled activities to ensure that operations are proceeding as planned	Did the program go as planned? How many food handlers have been trained compared with the number originally planned? How many households have been covered compared with the planned number?
Adequacy	Whether sufficient attention has been paid to certain previously determined courses of action	Has the program adequately covered all the target audiences? Has sufficient attention been paid to vulnerable groups (e.g., infants, pregnant women, and the elderly)?
Relevance	The rationale for selecting behavior in terms of relevance to foodborne diseases as well as the social and economic consequences	Is the behavior being changed in relevance to the foodborne diseases in question (e.g., hand washing will not be relevant to prevention of botulism)?

target groups. This involves translating the technical and scientific information into training programs and educational messages that are readily understood and accepted by the target populations, taking into account their culture and socioeconomic situation.

Before launching a long-term program, it may be necessary to carry out a pilot study to test its efficacy. Pretesting of educational material is important to ensure that the message is understood correctly. The message or material can be tested for clarity and accuracy on a small representative group of the general audience. Pretesting of the educational material is particularly important when the material is intended for persons of different cultures.

At the planning and implementation stages, it is also important to consider indicators that will be used in monitoring and evaluation. This will enable constraints to be identified and remedial actions to be taken if necessary.

Monitoring and Evaluation

Even when educational programs are well designed and implemented, monitoring and evaluation can significantly contribute to their improvement. They should be considered as integral parts of each program and should take place as the program proceeds as well as when it ends. The purpose of evaluation is to ascertain whether the intervention has been successful. Evaluation also helps to identify changes that may be desirable or necessary to improve the program. Pretesting of the education material and the research studies mentioned above are themselves forms of evaluation.

Depending on the results of the evaluation, or other findings and changes (e.g., change in the epidemiology of foodborne diseases, levels of food contaminants, food production practices, and emerging hazards), it may be necessary to bring changes to the educational plan.

Evaluation can be carried out according to criteria listed in Table 2.

Conclusion

To date, foodborne diseases remain a major public health problem. Health education in food safety is the cornerstone of strategies for the prevention of foodborne disease, keeping the population abreast with technological developments and enabling them to make informed choices. In principle, the entire population should receive education in food safety, as everyone has a role in food safety and everyone is a potential food handler or a consumer. To this end, a systematic, effective, and long-lasting approach is needed. Public health authorities must play the leading role, particularly as the medical community is often the most trusted source of information.

Many health education initiatives have failed because the fundamental conditions were not met. Some among these are as follows:

- Understanding that transfer of knowledge is necessary but not a sufficient condition for an effective program. Health education interventions based on the sole transfer of knowledge are not effective in changing behavior. There is a need for complementary measures such as policies, services and infrastructure, and social–cultural promotion. For instance, health education programs in the industrialized countries have for years provided knowledge on simple hygiene processes such as the need to wash one's hands after using the toilet. However, repeatedly, surveys show that deficient habits persist among food handlers. Similar observations have also been made in the medical community where physicians, both in the industrialized

and developing countries, neglect to wash their hands before examining their patients, in spite of the knowledge. Transfer of knowledge should go hand in hand with understanding and addressing factors that are a constraint or that can motivate the person to change behavior.

- Failures in the planning process. Health education should not be a shopping list of actions but should be based on scientific evidence of factors leading to illness and understanding the underlying sociocultural factors. Modifying behavior should have a significant impact on health. Many resources have been wasted promoting behavior that has little or no relevance to health problems.

In conclusion, health education in food safety should be considered as an essential public health function; together with regulatory measures, it is a pillar for an effective national food safety program. A rigorous scientific approach is essential as a poor or erroneous education is likely to do more harm than good.

Management of Food Safety in Food Service Sector

R Mitchell, Bob Mitchell Food Safety, Sevenoaks, UK

Glossary

Catering The preparation, storage and, where appropriate, delivery of food for consumption by the consumer at the place of preparation or at a satellite unit.
Cook-chill A specialized food production and distribution system for prolonging the life of prepared and cooked food by rapid chilling, storage at refrigeration temperatures, and reheating at the time of service.
Cook-freeze A specialized food production and distribution system for prolonging the life of prepared and cooked food by rapid freezing, storage at frozen temperatures, and reheating at the time of service.
Institutional catering Providing a mass catering service to people in an enclosed community such as a hospital, school, old people's home, or prison.
Mass catering The preparation, storage, and/or delivery and serving of food to a large number of people.
Open-air catering Providing a mass catering service to people out of doors such as in a disaster or civil emergency or attending an open-air sporting event or festival.
Sous-vide A specialized food production and distribution system for prolonging the life of food by cooking it in a vacuum pack, then rapidly chilling it for storage at refrigeration temperatures, and reheating at the time of service.
Travel catering Providing a mass catering service to people in transit such as on an aeroplane or ship or on holiday staying in a hotel or holiday camp.

Introduction

Mass catering technologies include the cook-freeze, cook-chill, and sous-vide systems. The situations where mass catering is used can present additional risks, for example, catering in hospitals or in schools can expose vulnerable groups to risks that might not affect the population at large.

Mass catering requires sophisticated technology, fully trained staff, intensive monitoring, and a considerable capital outlay. If these are not available then simpler, more labor intensive traditional systems need to be employed.

Mass Catering

Traditional catering is the professional supply of food to order for individuals or small groups. Consequently, a relatively small amount of food is prepared when ordered and served with little delay. In contrast, mass catering involves the preparation of large volumes of food to be stored in advance for a set period of time and then served not only to individuals and small groups but also often to a large number of people at the same time. In the current economic climate, there is an increasing demand for mass catering with its associated convenience and economy of scale. Preparing food in advance for serving at different times of the day can also be referred to as 'time-shift catering'. Mass catered food may also be prepared centrally and then distributed to a number of outlets or consumers that may be geographically situated over a wide area. Therefore, in order to be practical, economical, and safe, mass catering can necessitate the production, storage, distribution, and serving of food in bulk quantities. Traditional catering premises, or domestic kitchens for that matter, are not geared up for this type of operation. Bulk food preparation is predicated on the use of new technologies and specialized equipment and processing. These can introduce risks not typically seen with traditional small scale catering. As a result, the management of food safety in this food service sector has to develop novel food management techniques to account for these highly specialized production systems.

In short, mass catering requires sophisticated technology, fully trained staff, intensive monitoring, and a considerable capital outlay. If these are not available then simpler, more labor intensive traditional systems may need to be employed. Alternatively, less complicated meals or smaller quantities of food should be produced if circumstances allow this.

Management of Food Safety in Mass Catering

Although many of the principles of hygiene, food safety, and nutrition are common to all forms of catering, many systems of mass catering and the situations in which mass catering is employed present their own particular challenges. Many of the hazards are common to all forms of catering but the mass catering food environment is different. For example, when cooking bulk quantities of food, it is much more difficult

to deliver sufficient heat to kill vegetative pathogenic microorganisms than with smaller quantities of food. Similarly, it is much more of a challenge to subsequently cool bulk quantities of food and then chill or freeze them to prevent germination of spores and subsequent increase of vegetative cells to numbers of concern. Following this, reheating bulk quantities of food is much more difficult than for small-scale catering. Finally, serving bulk quantities of food at the same time presents many logistical challenges with numerous associated opportunities for cross-contamination from food handlers or other sources.

Risk assessment of the use of mass catering in the food service sector reveals an additional factor that demands major consideration. The hazard identification step requires an examination of the susceptibility of the exposed population to the potential hazards being assessed. As will be seen later in this article, mass catering food service techniques are sometimes used in hospitals, schools, care homes, and even in disaster situations where vulnerable groups that will have reduced resistance to foodborne illness will be present.

By definition, an outbreak associated with mass catering is likely to involve large numbers of people in some cases in the hundreds or thousands. An outbreak associated with mass catering also has the potential to be geographically widespread, either through people dispersing after consuming the contaminated food, for example, air travel or people coming from long distances for an event, whether a wedding reception or the summer Olympic Games.

It is not easy to find reliable statistics on the number of cases of foodborne illness caused by mass catering. Often the general term 'catering' is used, so it is difficult to discriminate between traditional and mass catering. Table 1 shows the verified outbreaks of foodborne illness in the European Union in 2009 by reported setting. The largest outbreak was caused by *Shigella sonnei*, involving 58 cases and took place in a workplace canteen. Todd et al. reviewed outbreaks where food workers have been implicated and reported that some of the outbreaks were very large; 11 involved more than 1000 persons, 4 with more than 3000 ill. The larger outbreaks tended to be extended over several days with a continuing source of infections, such as at festivals, resorts, and community events, or the contaminated product had been shipped to a large number of customers, for example, icing on cakes or exported raspberries. During an outbreak of salmonellosis caused by *Salmonella indiana* during the European Summit Conference in Maastricht in 1981, it is estimated that 600–700 of the 1000–1200 exposed persons became ill. The cause of the outbreak was probably a salad base, which was used in various snacks and cold dishes. Serious errors were made during preparation of this salad base which allowed the *S. indiana* present in the product to multiply on a large scale.

Table 1 Verified outbreaks of foodborne illness in the EU in 2009 by setting

	Percentage (N = 977)
Household	36.4
Restaurant, café, pub, hotel	20.6
Unknown	15.0
Temporary mass catering (fairs, festivals)	2.8
Hospital or medical care facility	4.8
Canteen or workplace catering	4.9
School, kindergarten	5.5
Other setting (nursing home, prison, boarding school, aircraft, ship, train)	9.9

[378 pp.]. doi:10.2903/j.efsa.2011.2090. Available online: www.efsa.europa.eu/efsajournal

Risks and Hazards Associated with Mass Catering

The risks and hazards associated with mass catering are more or less the same as with any other food production system and can be classified as biological, chemical, or physical. Biological hazards include: infectious bacteria, for example, *Salmonella* and *Listeria monocytogenes*; toxin-producing organisms, for example, *Clostridium botulinum*; and viruses, for example, norovirus. Biological hazards are controlled by following the general rules of food hygiene set out in the WHO Five Keys to Safer Food, namely: keep clean; separate cooked and raw; cook thoroughly; keep food at safe temperatures; and use safe water and raw materials. Generally speaking, foods should be cooked to an internal temperature of 70 °C. Chilled foods should be held at as low a temperature as possible, generally <5 °C depending on the food, whereas frozen foods are generally held below -18 °C. In any case, every effort should be made to avoid holding foods in the 'danger zone' of 5–60 °C for more than 2 h. Of course, the technical and practical challenges of achieving these requirements with high volumes of food are significantly more demanding for mass catering than for traditional catering and are discussed later in this article, along with control measures relating to more specialized products, for example, sous-vide foods.

Chemical hazards include some food additives and a range of food contaminants such as heavy metals, dioxins, radionuclides, veterinary drug residues, and pesticide residues as well as contaminants from processing and packaging or other environmental contaminants; allergens such as peanuts and naturally occurring toxins such as those from poisonous mushrooms or toxic algae in seafood. It is difficult, if not impossible, to eliminate chemical hazards from foods therefore controls focus on using uncontaminated raw materials and preventing contamination during processing, storage, and distribution. In terms of food allergens, all staff, including servers, should appreciate the importance of this subject and be sensitive to this issue when serving clients.

Physical hazards are myriad and include: metal filings, glass, jewellery, stones, and bone chips. Control measures include source control, for example, vendor certification and raw-material testing; or production control, for example, metal detectors and visual inspection.

General Risk Management

The Codex Alimentarius Commission has produced a code of hygienic practice for precooked and cooked foods in mass catering based on the principles of the hazard analysis critical control point (HACCP) system. It covers many of the general principles of food hygiene including and prerequisites to HACCP. Key points specific to mass catering are:

- Establishments should be located in areas, which are free from objectionable odors, smoke, dust, or other contaminants and are not subject to flooding. However, in order to allow for safe storage and processing of bulk quantities of food, mass catering really should take place only in specifically designed premises. Simply scaling up a hotel or restaurant kitchen is plainly not good enough. The equipment needs to be properly designed for the storage, chilling, freezing, cooking, and handling bulk quantities of food. Furthermore, it needs to be designed to operate hygienically and be easy to clean.
- As for all food premises, mass catering facilities not only need to be sited near a good infrastructure with potable water and a reliable power supply but must also avoid areas of heavy industry where environmental pollution might contaminate the food.
- Managers should arrange for adequate and continuing training of every food handler in hygienic handling of food and in personal hygiene so that they understand the precautions necessary to prevent contamination of the food. Training should initially cover the rules of general hygiene but then progress to be specific to the type of operation under consideration. However, many countries lack sufficient suitable skilled workers required for some of the more complicated modern specialized equipment and processes designed for mass catering. In addition, this industry sector is well known for its rapid turnover of staff. All of these factors can make it difficult to guarantee a workforce well trained in mass catering equipment and techniques. In some countries, the competent authorities will require records of any training undertaken to be kept for inspection.
- No raw materials or ingredient should be accepted by the establishment if known to contain parasites, microorganisms, or other hazards that will not be reduced to acceptable levels by normal plant procedures of sorting and/or preparation or processing. Catering for large numbers of people demands an adequate supply of raw materials of satisfactory safety and quality. This can place a significant strain on local food supplies, especially in developing countries or temporary sites such as festivals or disaster relief. Linked to the raw materials is a coincident need for trained staff and management as well as sufficient QA and laboratory analysis resources.
- Raw foods of animal origin should be stored between 1° and 4 °C. Other raw foods which require refrigeration should be stored at as low a temperature as quality permits.
- Frozen foods and raw materials should be stored at or below −18 °C.
- Reheating the food should be carried out rapidly: a temperature of at least 75 °C should be reached in the center of the food within one hour of removing it from refrigeration. The reheated food should reach the consumer as soon as possible and at a temperature of at least 60 °C.
- In self-service establishments, the foods should be protected from contamination and held at either below 4 °C or above 60 °C.
- Care needs to be taken with transportation of cooked meals so that they remain hot not only in the vehicle but also during distribution to the patrons who may be hospitalized patients or passengers in an aircraft.

New Technologies

Cook-Freeze and Cook-Chill

Cook-freeze is a specialized food production and distribution system for prolonging the life of prepared and cooked food by rapid freezing, storage at frozen temperatures, and reheating at the time of service. Meals are cooked at a central factory and then rapidly frozen and stored at temperatures of at least −18 °C and preferably as low as −30 °C. They are then distributed in refrigerated transport to where the food is to be reheated and served when needed. The length of storage depends on the food, but typically it can be stored for months. For longer storage, the food may be subjected to pasteurization after cooking.

Cook chill is similar to cook freeze except that the food is cooked but then stored and distributed at chill temperatures of 5 °C, or preferably, below. Organisms that survive the cooking process or contaminate the food after cooking can grow, albeit slowly, at chill temperatures, so these products have a much shorter shelf life than Cook-freeze products, typically 5 days or less. Hence, more attention needs to be applied to stock control for safety and quality reasons. The advantage for these foods over Cook-freeze relate mainly to the lower energy usage and the potential for a better quality final product. In contrast, cook-freeze requires more energy but is more flexible because of the longer shelf life of the product.

Cook-chill foods should be stored at below 5 °C. Because of this the organisms of most concern are those that have the potential to grow below this temperature after having survived the cooking process or re-contaminated the food after cooking. The main organism of concern is *L. monocytogenes*, especially for cook-chill foods with a shelf life of more than 5 days. The risk is managed by hygienic design of the production process and ensuring that every part of the dish receives a heat treatment of 70 °C for 2 min, or equivalent, on reheating. Risk management for psychrotrophic *C. botulinum* is discussed in the sous-vide section below.

For operations on the scale of mass catering, both systems require dedicated cooking equipment and design of the product to maximize its freezing or chilling and reheating properties. In particular, they demand modern equipment in order to facilitate rapid chilling or freezing of the product to limit or prevent the growth of pathogens. The key feature of blast chillers and blast freezers is that they rapidly reduce the temperature of hot foods to low, safe temperatures. Such equipment is not suitable for use in domestic kitchens because they can produce large amounts of condensate and so may require specially designed premises to pipe the condensate away from the food. They can be difficult to maintain and

repair and clean. Indeed, if not cleaned properly, the equipment itself can be a source of contamination, for example, by *L. monocytogenes*. In addition, they need a continuous supply of power as well as instructions for what to do if they fail or there is an interruption to the power supply.

Cook-chill and cook-freeze foods can require specialist reheating equipment because pathogenic organisms can still potentially be present. The main target group for cook-chill and cook-freeze foods is people who have no time or facilities to spend cooking. Typical categories would be schools, pensioners, and hospitals.

Sous-Vide

Sous-vide involves cooking a dish that has been vacuum packed before cooking. This has two food safety benefits compared to cook-chill. First, the exclusion of air from the vacuum bag greatly reduces the growth of aerobic bacteria and thus delays spoilage of the contents. Second, cooking in pack prevents recontamination by organisms such as *L. monocytogenes*. Pasteurizing sous-vide foods will kill vegetative pathogens but not spores. This includes spores of psychrotrophic *C. botulinum* (Types B, E, and F), an organism that can grow and produce potentially fatal neurotoxins under refrigeration (down to 3.3 °C) under anaerobic conditions: conditions that can apply to sous-vide foods. The risk of botulism is compounded by the absence of vegetative spoilage organisms that would otherwise out-compete the *C. botulinum* or spoil the product so that it would not be consumed. However, to date, there have been no reports of sous-vide foods held under refrigeration having caused any cases of botulism.

The following controlling factors can be used singly or in combination to prevent growth and toxin production by nonproteolytic *C. botulinum* in chilled foods with a shelf-life of greater than 10 days, the shelf-life beginning as soon as the controlling factors have been first applied:

- a heat treatment of 90 °C for 10 min or equivalent lethality,
- a pH of 5 or less throughout the food and throughout all components of complex foods,
- a minimum salt level of 3.5% in the aqueous phase throughout the food and throughout all components of complex foods,
- a water activity of 0.97 or less throughout the food and throughout all components of complex foods, and
- a combination of heat and preservative factors, which can be shown consistently to prevent growth and toxin production by nonproteolytic *C. botulinum*.

Microwave Reheating

Microwave ovens reheat foods by dielectric heating: electromagnetic radiation vibrates water molecules in the food to the extent that they generate heat, thereby cooking or reheating the food. It is well recognized that microwave equipment can suffer from uneven reheating, resulting in cold and hot spots. For this reason, the general advice is to use microwaves to reheat foods not cook them and ensure that the food reaches 70 °C for 2 min or equivalent or is 'piping hot throughout'. Domestic scale microwave ovens are not suitable for mass catering. Industrial scale microwave ovens should have fewer problems with uneven heating and use thermocouples to ensure that the target time/temperature is met.

Institutional Catering

Hospitals

Hospital catering presents a unique challenge to food safety because of the presence of various types of vulnerable groups: be they very young, elderly, pregnant, immunocompromised, or generally ill. Such consumers are potentially susceptible to hazards or potential hazards that might not have an effect on more robust 'healthy' people. Hence, food safety systems need to be applied even more scrupulously than for the general population at large. In particular, some susceptible groups such as immunocompromised patients will be at risk from organisms that would be considered to be opportunistic pathogens, for example, some strains of *L. monocytogenes*. Unfortunately, *L. monocytogenes* has been previously associated with cook-chill meals, so extra care needs to be taken when using such systems in hospitals.

It needs to be remembered that catering in hospitals is used for both patients and staff. Other factors that need to be borne in mind are the use of catering at off-peak times, such as night shifts, and the need to train staff on wards how to handle the foods safely. A number of outbreaks have been associated with catering in hospitals. In the UK, in 1984, an outbreak of *Salmonella* food poisoning at the Stanley Royd Hospital resulted in 19 elderly patients dying and another 300 patients and staff being taken ill. Numerous instances of basic food hygiene failures were found in the subsequent public inquiry.

Schools, Homes for the Aged and Meals on Wheels

As with hospitals, these tend to be populated by vulnerable groups – either the very young or the elderly. A peak demand can arise in the middle of the day, requiring the reheating or large amounts of chilled or frozen food at the same time. Meals on wheels are home delivered meal programs that deliver meals to elderly or disabled individuals at home who are unable to purchase or prepare their own meals.

In some cases the food is transported hot to the point of consumption. This means that the food will spend some time in the danger zone and care needs to be taken to ensure that the food is held hot for a short time and certainly never more than 2 h unless guaranteed to be above 60 °C. Failure to do this can result in food poisoning from either *Clostridium perfringens* or *Bacillus cereus* where the spores can germinate resulting in massive outgrowth of the vegetative cells.

In the UK, an outbreak of food poisoning after a meals-on-wheels lunch delivery affected 49 persons, one of whom died. *Bacillus cereus* and *Bacillus licheniformis* were isolated in large numbers from many of the patients, including the deceased and from the remains of the meal. Food kept warm during distribution was thought to have provided an ideal environment for bacterial multiplication.

The growth of the aging population is likely to make this form of food service more common in the future, reinforcing the need for good food safety management.

Open Air Catering

Disasters and Civil Emergencies

In the event of a disaster, bulk preparation of food is often the best use of resources. In addition, if circumstances permit, the food can be prepared in a facility where it can be protected from pests, vermin, and the weather.

Mass catering in the event of a disaster is particularly hampered by a number of factors. The first is siting: in some cases the refugees will have left the disaster area, and in other cases the refugees are still in the area and so food will need to be brought into them. In these situations there may be some choice available when siting the mass catering operation in which case appropriate consideration can be given to issues such as availability of dry ground, potable water, and an adequate power supply. In other cases, there may be little choice available for siting the operation.

It is important to remember the cultural aspects of food. For example, if the food is prepared by people of one cultural background, but the recipients are of a different cultural background, the recipients might not know whether the food was prepared properly and safely. There may be religious differences to consider as well.

Almost by definition, the population will be vulnerable to disease due to malnutrition; exhaustion; and lack of shelter, hygiene, and medical facilities. In such circumstance, even mild foodborne illness can be extremely serious. Climate change and the resulting extreme weather events, such as flooding, droughts, and hurricanes, are likely to increase the necessity for well managed mass catering disaster relief.

Festivals

In many ways, a large festival event can share the logistical problems of a disaster in terms of the need to feed a large number of people at site where catering is not normally performed. Of course, the recipients are more likely to be healthier and fitter than refugees.

Festivals tend to take place outdoors in the summer, making temperature control potentially difficult. Therefore, it is best if only small quantities of food are on display and these are monitored to ensure they are on display for as short a time as possible. Outdoor festivals will necessitate an adequate supply of clean potable water for drinking, cooking, washing, and other hygiene requirements.

Festival promoters should use only reputable experienced caterers, including smaller sub-contractors, for example, hot dog stands and outlets run by voluntary organizations. Many problems can be avoided if promoters liaise with the relevant competent food inspection authorities well in advance of the festival commencing. In 1988, attendees at an outdoor music festival that was held in Michigan became ill with *Shigella sonnei*. The onset of the illnesses peaked two days after the festival ended, after attendees had returned home. An uncooked tofu salad served on the last day was associated with risk of illness. A smaller outbreak of *S. sonnei* occurred among festival volunteers before, and during, the festival. There was limited access to soap and running water for handwashing.

Large Scale Sporting Events

Large scale sporting events such as the World Cup and the Olympic Games tend to be held in one place and at a specified time. They do involve large numbers of people congregating in one place for a limited time. Hence, facilities often need to be purpose built and are generally well designed if there is enough time to prepare for the event. However, the need to employ large numbers of catering staff for a limited time can impose limitations on the training available. This should not be skimped. In addition, commercial sponsorship tends to limit the catering activities to only those agreed by the organizers on behalf of the sponsors, but there can be large number of more opportunistic traders operating outside the zone of strict control. These need to be properly organized and inspected. Unfortunately, large scale sporting events such as the Olympic Games have proved to be a target for terrorism in the past, so there is an increased need for vigilance in these circumstances to protect against bioterrorism in the foods on offer at them. In the 2012 London Olympics particular care was taken with food supplies and thankfully no issues arose of which we are aware.

Travel Catering

Tourist Hotels and Holiday Camps

Catering at tourist hotels and holiday camps is vulnerable to food safety risks for a number of reasons. The tourist season is often seasonal meaning that there will be an increased demand for people to process and handle the food but for only a limited period. This can lead to difficulty in sourcing and training suitable staff with a consequential increased risk, from breaking basic food hygiene rules or from contamination via food handlers.

There has been an increase in the number of tourists seeking compensation if their holiday is affected. Payouts of millions of dollars are not uncommon, and there are now a plethora of websites advising people how to seek compensation. In addition to paying compensation, the hotel can suffer because of bad publicity either in the media or in the many holiday advisor and rating websites that have also sprung up.

Developing countries in particular rely on the tourist trade to generate employment and foreign currency. They can be hampered by lack of local amenities or suitably trained staff. In addition, there may cultural differences such that hygiene habits may differ or visitors from abroad may be exposed to new foods and thereby potentially to organisms they have not met before, resulting in illness. Travellers are generally advised to avoid raw milk and raw meats, unwashed fresh fruit and vegetables, and ice from untreated water. Even if the main food dishes are properly prepared and served using good hygienic practices, garnishes and side dishes that form the displays of elaborately decorated buffets may be a source of

contamination, not least if they are displayed for extended periods of time at high ambient temperatures. Although not exclusively foodborne, an outbreak of norovirus can shut down an entire hotel and the organism can be difficult to subsequently eradicate.

Air Travel

Aircraft have very limited space for sanitary facilities and food storage and processing materials. Hence, mass catering systems are used almost exclusively. The size can vary from a small kitchen to a large catering establishment producing many tens of thousands of meals per day, including provisions for long-haul flights. A single unit may have contracts with tens of airlines.

Serious problems can arise if a major food-poisoning outbreak occurs on board and the aircraft is far away from an airport and from adequate medical services. Foodborne illness can be extremely serious, especially during a prolonged international flight. In 1992, 75 passengers went down with cholera (from contaminated shrimp) on a flight from Lima, Peru, to Los Angeles. Ten of them were hospitalized and one died. Such emergencies can present significant problems because of the limited medical resources available on board.

The identification and investigation of an outbreak caused by a meal served on an aircraft is complicated if the causative agent has a longer incubation period than the flight takes and the passengers become ill after disembarkation. Those affected can travel to widely different destinations, making it impossible to recognize a common origin to their illness.

Some flight catering companies freeze samples from each batch of each meal so that they can later be analyzed if they are suspected of having caused illness. Cabin staff need to be trained in how to reheat and handle foods safely.

The safety of meals for technical crew such as pilots and flight engineers is even more critical than for passengers. In some instances, specific ingredients can be banned completely from flight crew meals, including all egg products and dairy products that have not been sterilized, for example, by ultra heat treatment. Individual meals can be labeled with the position of the crew member for whom they are intended, and the service designed such that no flight crew member eats any of the same products as their colleagues. This ensures that each pilot eats a different meal to minimize the risk of all the pilots on board being ill while the plane is in flight.

Great care needs to be taken when taking on drinking water. It is not unknown for aircraft to pick up untreated water at airports where the hygiene provisions are suspect and resulting in illness in the passengers when they get home. As many flights are associated with holidays abroad, there is also a significant industry of potential litigation associated with air travel. Todd *et al.* reviewed outbreaks where food workers have been implicated and reported 18 outbreaks associated with commercial travel in air flights, trains, and cruise ships over several decades.

Ships

In many ways cruise ships are like floating hotels with similar food safety risks and controls including displays of elaborately decorated buffets that can be a source of contamination if they are on display for extended periods of time at high ambient temperatures. Although not exclusively foodborne, an outbreak of norovirus can shut down the entire ship for many days as the organism can be difficult to subsequently eradicate. As for hotels and flights, there can be substantial litigation associated with cruise ship foodborne illness.

In 2001, the World Health Organization carried out a search of reports of an outbreak or incident of infection associated with a ship since 1970. They found more than100 outbreaks of food and waterborne diseases have been associated with ships. One-third of the outbreaks were foodborne and one-fifth waterborne. A wide range of pathogenic bacteria and parasites were implicated as well as viruses such as norovirus.

Factors contributing to the foodborne outbreaks included deficiencies in food hygiene and infected food handlers.

Rooney et al. reviewed data on 50 outbreaks of foodborne disease associated with passenger ships. The majority of reported outbreaks were associated with cruise ships and affected that almost 10 000 people. *Salmonella* spp. were most frequently associated with outbreaks. Factors associated with the outbreaks reviewed include inadequate temperature control, infected food handlers, contaminated raw ingredients, cross-contamination, inadequate heat treatment, and onshore excursions. Seafood was the most common food vehicle implicated in outbreaks.

Other Catering for Travellers

In a similar fashion to aircraft, food handling facilities on trains and coaches can be very limited. Often food will be available only at the train or coach station. If vending machines are used in these circumstances, then great attention has to be paid to cleanliness, temperature control, and stock rotation.

Banqueting

A banquet is a formal meal for a large number of people on a social occasion such as a wedding. The UK Health Protection Agency (HPA) revealed that more than 90% of outbreaks of *Campylobacter* food poisoning at catering venues in 2011 were linked to consumption of undercooked chicken liver pate. Fourteen outbreaks occurred in catering venues of which seven were linked to wedding receptions at hotels, banqueting venues, or public houses.

Banquets can be at risk because large numbers of people arrive needing to be served at the same time. Often foods more exotic than those normally eaten may served, introducing new organisms. Another risk factor is the need to employ large numbers of catering staff who may lack training in good hygiene.

Often the banquet may be held outside making the provision of potable water and other hygiene requirements difficult. Sometimes, for example, Christmas, a small business may take on a job bigger than its facilities can safely handle. Banquets can also use displays of elaborately decorated buffets that can be a source of contamination if they are on display for extended periods of time at high ambient temperatures.

Well-documented problems can occur when nonspecialized people such as a family or small caterer undertake to supply more people/food than they are used to with no training or facilities for bulk handling of food. This can be a recipe for disaster.

Food Safety in Hospitals and Other Healthcare Settings

BM Lund, Institute of Food Research, Norwich, UK
SJ O'Brien, University of Liverpool, Liverpool, UK

Glossary

Immunocompromised Having the immune response attenuated as a result of disease, malnutrition, administration of immunosuppressive drugs, age, or pregnancy.

Macrophage A tissue-based cell that can engulf and kill microorganisms and that secretes proteins that have an important role in the immune response.

Neutrophil The most abundant circulating white blood cell, which is recruited to inflammatory sites and can engulf and enzymically digest microorganisms.

Tumor necrosis factor alpha A secreted protein that functions as a mediator of immune and inflammatory reactions.

Vulnerability of People in Healthcare Settings

In healthcare settings a high proportion of people are liable, through age and/or illness, to be especially susceptible to foodborne and waterborne infection. In the USA vulnerable groups have been estimated to comprise almost 20% of the population. In the UK people aged over 65, who tend to show increased susceptibility to infection, form approximately 16% of the population; many of these and also younger people may suffer from conditions that increase susceptibility. Factors that increase susceptibility to infection, in particular to foodborne and waterborne disease, are shown in Table 1.

Supply of Meals in Healthcare Settings

Hospitals

In hospitals the meals may be freshly cooked onsite, or they may be cooked in advance using cook-chill or cook-freeze systems, either onsite or prepared offsite by a commercial organization. Cook-chill and cook-freeze systems afford flexibility in the preparation and serving of meals. Guidelines on their use for catering operations were published by the Department of Health (UK) (1989), the essential features of these systems are shown in Boxes 1 and 2.

Where the supply of meals is outsourced the supplier should be audited. In England and Wales the National Health Service (NHS) Supply Chain organizes central tendering for contracts to supply food to many hospitals within the NHS. The NHS Supply Chain ensures that their food products are sourced from approved suppliers who are audited to a standard that provides a due diligence defense for NHS trusts.

Many hospitals have canteens serving visitors, but inpatients, outpatients and staff can often also purchase food and drinks. The food from these outlets must also be safe for patients and staff.

Care Homes

In care homes meals may be freshly prepared onsite, but many also obtain meals prepared by commercial caterers.

Meals-On-Wheels

Hot meals or frozen meals are delivered to vulnerable people in their homes by a variety of providers.

Main Foodborne Microbiological Hazards

Improvements in sanitation and water supplies and the control of food production in industrialized countries mean that the major foodborne, including waterborne, pathogens responsible for illness differ from those in developing countries. For example, cholera is rare in industrialized countries but is common in parts of the world including regions of India and subSaharan Africa. It is associated particularly with a lack of safe water supply and with consumption of raw or undercooked shellfish. In hospitals in developing countries infections are a major problem. These infections can be attributed to lack of knowledge and training in infection control and inadequate infrastructure, resources, and systems of care.

In the USA between 2000 and 2008 eight pathogens were reported to cause the great majority of cases of foodborne illness, hospitalizations, and death due to known pathogens. Whereas norovirus caused the greatest number of reported cases, (Table 2) nontyphoidal *Salmonella* (NTS) caused the

 doi:10.1016/B978-0-12-378612-8.00348-6

Table 1 Host factors that increase the risk of foodborne and waterborne infection or the severity of the disease

Host factor	*Reason for increase in risk or severity*
Primary immunodeficiency	Immune system inadequate to combat infections
Secondary immunodeficiency: resulting from leukemias, treatment with cytotoxic drugs during organ transplantation or for cancers or autoimmune disease, irradiation treatment, treatment with corticosteroids, infection with human immunodeficiency virus (HIV) removal of the spleen, malnutrition involving protein, calories, vitamins or trace minerals.	Immune system inadequate to combat infections
Excessive iron in the blood	High levels of iron increase growth of certain pathogens
Cirrhosis and other liver disease, kidney function (alcoholism)	Iron overload, immune system dysfunction
Stress, e.g., as a result of surgery	Changes in metabolism reduce resistance to infection
Diabetes	Poor glycaemic control is associated with impaired neutrophil functions
Pregnancy	Altered immunity
Age <1 year	Gut microflora allows colonization by spores of *Clostridium botulinum*
Age <5 years	Lack of developed immune system, smaller infective dose required for infection
Age >65 years	Immune system deteriorating, also affected by chronic ailments
Consumption of antacids, particularly proton pump inhibitors	Increased pH in the stomach, increasing survival of pathogens
Consumption of large volumes of liquids, including water	Dilution of acids in the stomach
Ingestion of fatty foods (e.g., chocolate, cheese, hamburger) containing pathogens	Fat protects pathogens from acid in the stomach

Box 1 Features of cook-chill meals for catering operations

1. Full cooking of food. The temperature throughout the food should be held above 70 °C for not less than 2 min
2. Fast chilling
3. Maintain at 0–3 °C during storage and distribution for upto 5 days including the day of cooking
4. Immediately after removal from chill storage reheat to an internal temperature of at least 70 °C and maintain at not less than 70 °C for at least 2 min
5. Service of food should commence within 15 min of reheating. The temperature must not fall below 63 °C
6. Foods intended to be eaten cold or at room temperature should be consumed, preferably, within 30 min of removal from chilled storage

Box 2 Features of cook-freeze meals for catering operations

1. Full cooking of food. The temperature throughout the food should be held above 70 °C for not less than 2 min
2. Fast freezing
3. Storage at -18 °C or below
4. Thaw food and hold at or below 3 °C throughout storage and distribution
5. For hot meals, reheat to an internal temperature of at least 70 °C and maintain at not less than 70 °C for at least 2 min
6. Service of food should commence within 15 min of reheating. The temperature must not fall below 63 °C
7. Foods intended to be eaten cold or at room temperature should be consumed, preferably, within 30 min of removal from chilled storage

greatest number of hospitalizations (Table 3) and NTS, *Toxoplasma gondii*, and *Listeria monocytogenes* caused the greatest number of deaths (Table 4).

In Australia between 2001 and 2008, 5.9% of all reported food- and water-borne outbreaks occurred in long-term-care facilities for elderly residents. *Salmonella* caused 17 outbreaks, *Clostridium perfringens* 14 outbreaks, *Campylobacter* 8 outbreaks, and norovirus 1 outbreak; of 15 outbreaks of unknown etiology 11 were suspected to be due to *C. perfringens*. Puréed foods were implicated in several outbreaks.

Infection with Norovirus generally causes relatively mild and short-term symptoms, but in the elderly, chronically ill, or immunocompromised patients it can result in death.

Source: Reproduced from Food and Agriculture Organization of the United Nations (2004) Buchanan R, Lindqvist R, Ross T, Smith M, Todd E, and Whiting R. Risk Assessment of *Listeria monocytogenes* in ready-to-eat foods. Microbiological Risk Assessment Series 5. Rome: FAO/WHO. Available at: http://www.fao.org/docrep/010/y5394e/y5394e00.htm (accessed on June 2013).

NTS and *Campylobacter* infections have the most severe effects in elderly persons, particularly in those with a comorbidity. In infants, the elderly, and immunocompromised people NTS bacteraemia may occur and be life-threatening. Younger people with HIV infection, autoimmune diseases, and/or immunosuppressive therapy are at an increased risk of NTS bacteraemia; elderly people, often with underlying conditions, are liable to NTS bacteraemia and extraintestinal infections.

Toxoplasma gondii is a rare cause of illness after transplant and can result in encephalitis, myocarditis, or disseminated infections, and cause high mortality. A high proportion of the population shows evidence of latent infection with *Toxoplasma* and reactivation of infection can occur as a result of immunosuppression. Prophylactic use of trimethoprim-sulphamethoxazole (TMP-SMX) against *Pneumocystis jirovecii* pneumonia generally inhibits *T. gondii*, but cases of toxoplasmosis tend to occur when TMP-SMX prophylaxis is discontinued because of ill effects. Toxoplasmosis is also a risk for cancer patients and has been reported in patients treated with tumor necrosis factor alpha (TNF-α) inhibitors for rheumatoid arthritis or Crohn's disease.

Toxoplasmosis can result from congenital infection, primary infection, allograft infection, or reactivation of latent infection as a result of immunosuppression. In women who are infected with *Toxoplasma* during pregnancy there is a risk of transmission to the fetus. Infection during early pregnancy may cause fetal death and abortion or severe damage including chorioretinitis, intracranial calcification, hydrocephalus, or microcephalus. Infection during late pregnancy is often subclinical in the newborn with manifestations such as retinochoroiditis or, rarely, neurological disorders.

Listeria monocytogenes is of particular concern in vulnerable people because it causes septicemia and meningitis and has a case fatality of 20–30%. The elderly and those with preexisting medical conditions are particularly susceptible (**Table 5**). In pregnant women infection usually causes a mild, flu-like illness, but the bacterium can cross the placenta and infect the fetus, leading to abortion, stillbirth, or delivery of an acutely ill baby.

Immunocompromised patients are at particular risk of infection by *Pseudomonas aeruginosa*. A range of reservoirs exist in hospitals, including potable water.

These examples illustrate the increased risk of infection and of serious illness in vulnerable groups of the population resulting from exposure to foodborne pathogens.

Examples of Outbreaks and Cases of Foodborne Disease in Healthcare Settings

Foodborne outbreaks have been reported in different types of healthcare settings (**Table 6**).

It is probable that only a proportion of cases and outbreaks in healthcare settings are reported and described in scientific publications. Several themes emerge from reports of outbreaks:

1. Outbreaks in healthcare settings can result in a high mortality. For example, the outbreak due to *Escherichia coli* O157 in a nursing home in Canada in 1985 resulted in the death of 17 of the 55 residents affected (31%) and the outbreak due to *L. monocytogenes* in hospitals and nursing

Table 6 Selected outbreaks of foodborne illness in healthcare settings

Place, date,	*Causative organism*	*Setting*	*Cases (deaths)*	*Food implicated*	*Factors leading to outbreak*	*References*
Austria, 2006	*Campylobacter jejuni/coli*	Tertiary care hospital	Patients, 7 (0), staff, 14 (0)	Poultry dishes	Food prepared in hospital kitchen with recently established cook-chill process and no Hazard Analysis Critical Control Point system	Jelovcan *et al.* (2008)
UK, 1995	*Clostridium perfringens*	Hospital	17 (0)	Precooked, vacuum sealed pork	Faults at company that supplied ready-cooked joints; cooked meat had only cooled to 28 °C after 50 h	Regan *et al.* (1995)
Australia, 1997	*C. perfringens*	Nursing home	Residents, 25 (1)	Pureed food	Not reported	Tallis *et al.* (1999)
Japan, 2001	*C. perfringens*	Home for senior citizens	90 (0)	Boiled beans	Beans cooked in large quantities, cooked slowly, not reheated adequately before serving	Tanaka *et al.* (2003)
Belgium, 1998	*Cronobacter (Enterobacter) sakazakii*	Neonatal intensive care unit	12 (2)	Powdered milk formula	Powder contaminated	Van Acker *et al.* (2001)
Mexico, 2010	*Cronobacter (Enterobacter) sakazakii*	Maternity hospital	2 (0)	Powdered infant formula	Powder rehydrated at 45 °C instead of recommended 70 °C	Flores *et al.* (2011)
Canada, 1985	*Escherichia coli* O157	Nursing home	Residents, 55 (17), staff, 18 (0)	Ham or cheese sandwiches	Food handler who prepared sandwiches had recently recovered from diarrhea	Carter *et al.* (1987)
USA, 2003	*E. coli* O157	Nursing home	Residents, 32 (2), staff, 14 (0)	Raw spinach	Not reported	Reiss *et al.* (2006)
Finland, 1998–1999	*Listeria monocytogenes*	Tertiary care hospital	25 (6)	Soured cream butter	Outbreak strain in dairy environment and in butter	Lyytikäinen *et al.* (2000)
Germany, 2006–07	*Listeria monocytogenes*	Hospital	11 (5)	Ready-to-eat, – presliced, scalded sausages	Low number of *L. monocytogenes* found in sausages and in environment of factory	Winter *et al.* (2009)
Norway, 2007	*L. monocytogenes*	Cancer and transplantation hospital	15 (3)	Camembert cheese made with pasteurized milk	Contamination in factory after pasteurization of the milk	Johnsen *et al.* (2010)
Canada, 2008	*L. monocytogenes*	Hospitals, nursing homes	57 (21)	Delicatessen meats from external supplier	Contamination from meat slicer, inadequately cleaned, with meat residue deep inside slicing mechanism	Weatherill (2009)
Northern Ireland, 2008	*L. monocytogenes*	Two hospitals	7 (3)	4 cases linked to sandwiches	*L. monocytogenes* found in sandwiches at <20 cfu g^{-1}. Temperature control during distribution and service unreliable	Irvine (2009)
UK, 2008	*L. monocytogenes*	Hospital	3 (0)	Probably sandwiches	*L. monocytogenes* found in sandwiches, prepared by external supplier, at <20 cfu g^{-1} and also on cutter blade in production environment. Temperature control and storage in hospital defective	Health Protection Agency (2008)
USA, 2008–09	*L. monocytogenes*	Hospital	5 (3)	Tuna salad	Contamination of tuna from the environment; tuna salad held at 5 °C for up to 4 days	Cokes *et al.* (2011)
Denmark, 2009	*L. monocytogenes*	Meals-on-wheels delivery	7 (2)	Sliced, cooked beef served with sauces and vegetables; intended for microwave cooking by consumer	Beef had been cooked by the supplier at a lower temperature than usual. Four patients had cancer, one had systemic lupus erythematosus, three were aged >80	Smith *et al.* (2011)

(*Continued*)

Table 6 Continued

Place, date,	*Causative organism*	*Setting*	*Cases (deaths)*	*Food implicated*	*Factors leading to outbreak*	*References*
Germany, reported 2008	*Pseudomonas aeruginosa*	University hospital, intensive care units	19 (4)	Bottled still water (BSW)	Unopened bottles of BSW contained outbreak strain. German legal requirement specified absence in 250 ml	Eckmanns *et al.* (2008)
UK, 1993	*Salmonella* Enteritidis	Two hospitals with shared catering	Patients, 22, staff, 7 (0)	Association with meals prepared by one asymptomatic carrier	Three chefs were asymptomatic carriers	Dryden *et al.* (1994)
USA, 1993–94	*Salmonella* Senftenberg	Hospital	Patients, 18 (0), staff, 4 (0)	Suspected contamination from turkey	Deficient processes in kitchen, some patients immunosuppressed Possibly >200 persons affected	L'Ecuyer *et al.* (1996)
Brazil, 1999–2000	*S.* Enteritidis	Tertiary care hospital	Patients, 8 (3)	Commercial, enteral diet	Contamination of egg albumin, lyohilized and used in enteral diet	Matsuoka *et al.* (2004)
Netherlands, 2001	*S.* Enteritidis	Hospital and nursing home served by same hospital kitchen	82 (5)	Bavaroise	Raw eggs used, underheated, no temperature checks	Bruins *et al.* (2003)
Australia, 2001	*Salmonella* Typhimurium	Aged care facility	Residents, 16 staff, 2 (0)	Rice pudding, meat-based potato pie	Raw shell eggs whisked into rice pudding immediately before serving, and added to potato topping of pie before lightly browning	Tribe *et al.* (2002)
UK, 2002	*S.* Enteritidis	Hospital	29 (0)	Imported eggs	Eggs contaminated with outbreak strain and undercooked	Public Health Laboratory Services (PHLS) (2003)
Greece, 2005	*S.* Enteritidis	Hospital	Patients, 86 (2), visitors, 31, staff, 16	Association with roast chicken, spaghetti, cheese	Cross-contamination of food, inadequate temperature control and/or inadequate cooking	Gikas *et al.* (2007)
Germany, 2006	*S.* Enteritidis	Nursing home	Patients, 94 (1), staff, 17	Cakes supplied by outside baker	Cream cakes contaminated and not adequately refrigerated	Frank *et al.* (2007)
Australia, 2008	*S.* Typhimurium	Aged care facility	10 (0)	Chocolate mousse dessert	Dessert made with raw eggs. Free-range, second-grade eggs, some cracked and dirty, were used	Roberts-Witteveen *et al.* (2009)
Australia, 2010	*Salmonella* Infantis	Aged care facility	22 (2)	Thickened fluid added to food to promote safe swallowing, or used for taking medication	Probable contamination of thickened fluid from chicken mince in kitchen	Najjar *et al.* (2012)
Sweden, 1999	Norovirus	30 day-care centers served by the same caterer	400 including secondary spread (0)	Pumpkin salad	Contamination by food handler	Götz *et al.* (2002)
Denmark, 2005	Norovirus	Hospital, 2 nursing homes, meals-on-wheels service	Patients, ~970 staff, (0)	Imported, frozen raspberry pieces	Contamination during growth/harvesting on several small-scale farms.	Falkenhorst *et al.* (2005)
Austria, 2009	Norovirus	Hospital and rehabilitation center	114 (0)	Sliced, cold sausage; meat dish with salad; spinach pancake	Contamination by one of five asymptomatic excretors among the kitchen staff who prepared the food	Schmid *et al.* (2011)

homes in Canada in 2008 resulted in death of 21 of 57 residents affected (37%).
2. Asymptomatic chefs or other food handlers have been linked to several outbreaks. For example, that due to *E. coli* O157 in a nursing home in Canada in 1985, two outbreaks linked to *Salmonella* in the UK in 1993 and in Greece in 2005, and two linked to norovirus in Sweden in 1999 and in Austria in 2009.
3. Food handlers may be the victims of an outbreak rather than the cause and epidemiological analysis must distinguish between these two possibilities.
4. Serving high-risk foods to vulnerable patients has caused several outbreaks. For example, in several of the outbreaks due to *Salmonella* spp. raw eggs were used and were undercooked, despite the known risk of contamination of eggs with *Salmonella* particularly if the eggs are from stocks not immunized against *S.* Enteritidis. A further example is the supply to patients of sandwiches, sausages, or delicatessen meat containing low numbers of *L. monocytogenes*.

Factors Leading to Foodborne Disease in Healthcare Settings

Some of the main factors leading to foodborne disease in these settings are:

1. Food from unsafe sources;
2. Inadequate cooking;
3. Improper holding temperatures;
4. Contaminated equipment and cross contamination;
5. Poor personal hygiene.

Food from Unsafe Sources

It is a particular problem in the case of foods that are not subjected to a processing that will inactivate foodborne pathogens. For example, the series of outbreaks of norovirus infection in Denmark in 2005 was associated with one large batch of frozen raspberries, composed of fruit grown on several small-scale farms in Poland (Table 6).

Inadequate Cooking

This may have contributed to the outbreak of listeriosis associated with a meals-on-wheels delivery in Denmark (Table 6). UK advice is that foods should be cooked so that the temperature throughout the food is held at 70 °C or higher for at least 2 min, or equivalent heat treatment, to give sufficient inactivation of nonspore-forming microorganisms. The US Food and Drug Administration (FDA) Food Code specifies temperatures and holding times for cooking specific foods, for example, a temperature of 74 °C throughout the food for 15 s for poultry.

Inadequate Cooling

Cooked foods should either be eaten immediately, or kept for a short time at a temperature higher than 63 °C, or cooled rapidly and kept below 7–8 °C (ideally below 4 °C) to control clostridia, particularly *C. perfringens*, and other bacteria, and reheated to at least 72 °C before consumption. Spores of *C. perfringens* can survive cooking and give growth of the bacteria at temperatures between 12 °C and 52 °C. In the UK and the USA guidelines for cooling cooked foods are designed to ensure that no more than a tenfold increase in numbers of *C. perfringens* can occur during cooling. A computer program (perfringens predictor) is available that makes it possible to determine whether any proposed rate of cooling will comply with the UK and the US guidelines. Two of the three outbreaks of infection with *C. perfringens* in Table 6 were attributed to inadequate cooling of cooked food.

Contaminated Equipment and Cross Contamination

This led to the outbreak of listeriosis in Canada in 2008, which contributed to the deaths of 21 people (Table 6). It required considerable time to take meat-slicing machines apart, thoroughly sanitize, and reassemble. This limited effective cleaning. Meat residue was found deep inside slicers, providing a niche where *Listeria* could grow and contaminate meat during slicing.

Poor Personal Hygiene

Asymptomatic carriers and food handlers continuing to work while infected led to outbreaks of *E. coli* O157 in Canada in 1985, *S.* Enteritidis in the UK in 1993 and in Greece in 2005, and norovirus in Sweden in 1999 and Austria in 2009 (Table 6).

Outbreak investigations refer frequently to inadequate levels of staffing in the kitchen of hospitals and care homes, poor training, low wages, and lack of support from managers.

Prevention of Foodborne Disease in Vulnerable People in Healthcare Settings and in the Community

Control of Food Provision

The Food Hygiene (England) Regulations 2006 and similar Regulations in Scotland and Wales, gave effect to European Community Regulations that include a requirement that food businesses put in place, implement, and maintain procedures based on the principles of Hazard Analysis Critical Control Point (HACCP). The HACCP system is designed to ensure that hazards are prevented, eliminated, or reduced to an acceptable level before a food reaches the consumer, and involves seven principles.

In order for a HACCP system to be effective, programs to control basic operational conditions and sanitation (prerequisite programs) must be in place. These should include, for example, good design of premises, cleaning and training, good hygiene practices, use of approved suppliers and supplier auditing schemes, and other programs.

People like the consultant in communicable disease control, infection control team, and local environmental health officers should advise the catering management team in healthcare facilities on all aspects of food hygiene.

Hospitals and other healthcare facilities should provide adequate staffing for catering service, provide suitable training and pay rates, and allow paid leave if staff are infected. In the UK it is advised that, in general, food handlers suffering from gastroenteritis should be excluded from work for at least a period of 48 h after symptoms stop of their own accord or from the end of treatment with medication such as antidiarrhoeal drugs. In the case of illness caused by *Salmonella* Typhi or *S*. Paratyphi, verocytotoxin-producing *E. coli*, and Hepatitis A virus, longer periods of exclusion are required and medical advice is necessary. Anyone who has household contact with someone infected with *E. coli* O157 should be excluded from direct handling or serving of open, ready-to-eat foods and, if they are a parent, excluded from all food handling duties and areas until the patient has been given microbiological clearance. The FDA Food Code stipulates exclusion of food handlers showing symptoms of these infections and conditions for reinstatement. It also prescribes that a food employee who is diagnosed with symptoms of infection with norovirus, *Shigella*, enterohaemorrhagic *E. coli*, or Shiga toxin-producing *E. coli* but is asymptomatic, or has a sore throat with fever, should be excluded if they work in a food establishment serving a highly susceptible population, or restricted if they work in an establishment not serving a highly susceptible population. If staff are not paid when they are excluded from work this can lead to them working while ill and can result in food safety problems.

A survey in the USA found that 4.7% of food workers in the retail industry (approximately 900 000 people) continued working while they were ill with diarrhea or vomiting.

Types of Food Served to Vulnerable People, and Advice for These People

A low microbial diet is one from which certain foods are excluded and safer foods are substituted in order to reduce the risk of foodborne infection. A low microbial diet is recommended for hematopoietic stem cell transplant and solid organ transplant patients.

The American Cancer Society advises that "a low microbial diet (neutropenic diet) may be suggested if a patient's absolute neutrophil count (ANC) is low." An ANC of $<1000\ \mu l^{-1}$ means that the immune system is weak, an ANC of $<500\ \mu l^{-1}$ for a few days results in a high risk of infection, and an ANC of $<100\ \mu l^{-1}$ for more than a week means that the risk of infection is extremely high.

Many hospitals recommend low microbial diets for high-risk patients.

Guidelines in Scotland advise that a Grade 1 Neutropenia diet is used for hospital patients with a neutrophil count of $500–2000\ \mu l^{-1}$ and a more restricted, Grade 2 Neutropenia diet is used for patients with a neutrophil count of $<500\ \mu l^{-1}$.

There are differences between the components of low microbial diets specified by different organizations, and agreement on the components of such a diet would be valuable.

In Germany low microbial diets were only considered for patients with severe neutropenia (neutrophils $<500\ \mu l^{-1}$); in the outbreak of listeriosis in a hospital in Germany in 2006–08 (Table 6) none of the patients met this criterion, and had received regular food during their hospital stay. But the patients were being treated with corticosteroids and proton pump inhibitors; corticosteroids suppress activity of macrophages, and association has been reported between intake of corticosteroids and listeriosis. It was suggested that food items served in hospitals could be classified as 'food intended for special medical purposes,' and should include the criterion of absence of *L. monocytogenes* from 25 g.

It has been argued that evidence for the effectiveness of low microbial diets is lacking, but it is clear that certain foods carry a risk of infection with foodborne pathogens. It is not acceptable to subject severely ill patients, who are receiving expensive and complex treatments, to foods that may contain pathogenic microorganisms, particularly because equally nutritious and safer foods are available.

Following the outbreak of listeriosis in the USA associated with tuna salad (Table 6), a survey was made of food policy in 54 New York City hospitals – 9 public and 45 private. 29 (54%) of the hospitals reported contracting their food service to an outside provider. Of the 54 hospitals, 72% and 52%, respectively, had an obstetrics or an oncology unit, 19% had a solid organ transplant unit, and 20% had a bone marrow transplant unit. Of 53 responding hospitals 81% reported serving ready-to-eat deli meat to any patient in their hospital and only 25% of 16 responding hospitals reported having a policy that specified that ready-to-eat deli meats must be heated until steaming hot before they were served in patient meals. This is despite the fact that ready-to-eat deli meats are liable to contamination with *L. monocytogenes* and have been associated with outbreaks of listeriosis (e.g,. Table 6).

The FDA (2012) has published the following brochures or fact sheets, which give advice to vulnerable people:

1. Food Safety for People with Cancer;
2. Food Safety for Transplant Recipients;
3. Food Safety for People with HIV/AIDS;
4. Food Safety for Pregnant Women;
5. Food Safety for Older Adults;
6. Food Safety for People with Diabetes.

Each of these brochures contains guidelines on selecting lower risk foods and advice on purchasing, storing, and cooking foods.

Several groups of workers have recommended that patients being treated with TNF-α inhibitors should be advised about specific high-risk foods to avoid.

An enteral diet was the cause of one nosocomial outbreak in Brazil (Table 6). In developed countries commercial, sterile, enteral feeds are available, but in some countries hospital-prepared enteral feeds may still be used. Some of these feeds contained high numbers of bacteria, and the use of HACCP during reconstitution, supplementation, or preparation, or use of commercial, sterile products is advocated. In England and Wales it is recommended that, in order to reduce the risk of contamination, prepackaged, ready-to-use feeds should be used in preference to feeds requiring decanting, reconstitution, or dilution.

Drinking Water and Ice

Some outbreaks of nosocomial infection, particularly those due to *P. aeruginosa*, have been linked to tap water; a few have been attributed to tap water used for consumption. To prevent such infections, recommendations were made to prevent contamination of jugs used for drinking water for patients and for limiting the time for which jugs of drinking water are allowed to stand before use.

Guidelines in the UK and the USA advise certain immunocompromised patients to boil all drinking water to avoid the risk of *Cryptosporidium* infection. UK guidelines state that persons with certain T-cell deficiencies (including patients with HIV infection) should boil and cool their drinking water, from whatever source, and that ice cubes should be prepared from boiled and cooled water. It has been suggested that the use of end-line water filtration was the best way to provide drinking water for immunocompromised patients, provided that there are arrangements to ensure that filter cartridges are changed at appropriate times.

Bottled, still water caused an outbreak of infection with *P. aeruginosa* in a tertiary care hospital in Germany, which resulted in pneumonia in many patients (Table 6). European Community standards for bottled water specify the absence of *P. aeruginosa* in any sample of 250 ml, but increase in numbers can occur after bottling and this bacterium has been found in bottled, noncarbonated water from various countries.

Ice and ice-making machines have also been the cause of nosocomial infections and recommendations regarding the purchase, use, and maintenance of such machines have been made as part of Infection control. It was advised that ice made in automated ice machines should not be given to immunocompromised patients.

Powdered Infant Formula (PIF)

PIF has been responsible for infection of infants with *Cronobacter sakazakii* (*Enterobacter sakazakii*) and related organisms, and *Salmonella*. Measures to prevent contamination during commercial production have been described. PIF is not sterile, and if these bacteria are present they can survive for long periods in the dry powder. Hygiene during reconstitution and storage at low temperature is important for maintaining safety. For high-risk infants (preterm, low birth weight, immunocompromised) the use of sterile, ready-to-feed, liquid formula is recommended. Precautions required when reconstituting PIF include treating bottles with boiling water, reconstituting in water that has been boiled and cooled to not less than 70 °C, and storage of reconstituted formula below 5 °C.

Antimicrobial Prophylaxis

Antimicrobial prophylaxis is used widely during treatment of many groups of vulnerable people, particularly those affected by neutropenia. Recommendations have been made that this prophylaxis should be limited to patients with severe neutropenia.

TMP-SMX is used widely in transplant centers, primarily to prevent *Pneumocystis* pneumonia. This antimicrobial is also effective in preventing infection with *L. monocytogenes* and *T. gondii* and may reduce the incidence of *Salmonella* infections, but some resistance has been reported in *Salmonella*. Prophylactic use of TMP-SMX has also been recommended during treatment of certain cancers and this, or other antibacterials, for prophylaxis in persons receiving TNF-α inhibitors for treatment of rheumatoid arthritis or Crohn's disease.

The development of antibiotic-resistance in microorganisms and the need to control the use of antibiotics are liable to limit their use in these situations. This emphasizes the fact that environmental precautions, including avoidance of provision of high-risk foods to vulnerable people, are essential in preventing infection in these people in healthcare settings.

Conclusion

A high proportion of people in hospitals and other healthcare settings is particularly susceptible to infection as a result of their disease, of medication, or because their immune system is compromised as a result of age or pregnancy. It is particularly important to ensure the microbiological safety of food supplied to people in these settings. Suppliers of food in these settings are required to have in place a HACCP system, whether the food is prepared in a hospital, in an institution, or by an external supplier. For immunocompromised patients a low microbial diet, which excludes higher risk foods and substitutes safer foods, is important for avoidance of infection. Guidance on the choice of foods to avoid infection is also important for vulnerable people in the community.

Food Safety and Quality Management Systems

DL Newslow, D. L. Newslow & Associates, Inc., Orlando, FL, USA

Glossary

Audit An evaluation to determine if activities and results comply with defined requirements.

Benchmarking Benchmarking is a methodology that is used to sea'rch for best practices. It can be applied to strategies, policies, populations, processes, products, and organizational structures. The global food safety initiative (GFSI) applies the benchmarking process for its approval of food safety management system schemes comparing these to the most current version of the GFSI Guidance Document. (ISO 9000, 9001, and 9004, Quality Management Definitions.)

Corrective action An action or step taken to eliminate the causes of an existing nonconformance. This is a formalized process that requires root cause analysis, identified actions to be taken to correct the situation in a timely manner based on the risk of the situation, actions required to minimize or prevent its recurrence, and the evaluation of effectiveness to ensure that the action or actions applied are effective. Corrective actions address actual problems thus the corrective action process may be considered a problem-solving process. (ISO 9000, 9001, and 9004, Quality Management Definitions.) When related specifically to the Hazard Analysis Critical Control Point (HACCP)/food safety program, a corrective action is defined as 'any action to be taken when the results of monitoring at the CCP indicate a loss of control.'

Food safety management Food safety management includes all the activities that organizations use to direct, control, and coordinate food safety. These activities include formulating a food safety policy and setting food safety-related objectives.

Food safety management system A food safety management system is a set of interrelated or interacting elements that organizations use to direct and control how food safety-related policies are implemented and food

safety-related objectives are achieved. Food safety management systems are usually developed based on the requirements of a food safety management system standard and also on requirements defined by Codex Alimentarius (www.codexalimentarius.org).

Hazard Analysis Critical Control Point Codex Alimentarius (www.codexalimentarius.org) defines 'HACCP' as the process that is used to identify, evaluate, and control (or prevent) hazards that are significant for food safety. Considered a process tool to identify and assess existing and potential food safety hazards to ensure the production of a safe product.

Internal audit Activity designed to apply a systematic, disciplined approach assessing compliance and performance of an organization's policies and procedures to a specific quality and/or food safety standard, procedure, and/or guideline(s). 'Internal Audits' are performed within an organization to measure its own performance, strengths, and weaknesses against its own established procedures and systems.

Nonconforming Situation Also referred to as a 'nonconformity' is considered a failure (major) or potential failure (minor) to meet a specified requirement. A requirement is a need, expectation, or obligation. It can be stated or implied by an organization, its customers, or other interested parties. (ISO 9000, 9001, and 9004, Quality Management Definitions.)

Preventive action A preventive action is a step taken to remove the cause of a potential nonconformance and the action put in place to correct the situation preventing the nonconformance. The preventive action process is designed to prevent occurrence of nonconformities or situations that do not yet exist. Preventive actions address potential problems, problems that have not occurred thus the preventive action process may be considered a risk analysis process. (ISO 9000, 9001, and 9004, Quality Management Definitions.)

Second party audit Also known as an external audit that is usually performed by a company representative from an outside source, such as a customer.

Third party registration audit This is performed by an independent, accredited registrar independent of any involvement with the company business. Note: the registrar has been accredited to perform the registration audit to the specific standard of choice.

Understanding the Management System Standards

ISO 9000 Series – Quality Systems Requirements

Because the requirements of ISO 9001 truly provide the foundation for most, if not all, management system-based standards, it is important to initially understand the basis and foundation of this standard. '*Quality Management System*' is a term that has evolved over the years with the inception of the ISO 9000 standards in 1987. ISO 9001 is an international standard directed at the quality management process of an organization. However, this statement can be misleading because this standard focuses on an organization's complete system. The system is made of processes within processes that result in a total 'system.' Although the title is 'quality' management system, these requirements focus on the complete system and its ability to meet customer requirements while continuously improving. Quality management includes all the activities that organizations use to direct, control, and coordinate quality. These activities include formulating a quality policy and setting quality objectives. They also include quality planning, quality control, quality assurance, and quality improvements. A quality management system is a set of interrelated or interacting elements that organizations use to direct and control how quality policies are implemented and quality objectives are achieved. A Food Safety Management System is the overall defined organizational structure, procedures, processes, and resources put into place to define, implement, and maintain compliance to a specific quality and/or food safety management standard. (ISO 9000, 9001, and 9004, Quality Management Definitions.)

A brief background of how ISO 9001 came about focuses on the need for consistency and harmonization in international trade dating back as early as NATO documents AQAP-1 in 1968. In 1983, the International Organization for Standardization established Technical Committee 176 to develop an international standard that would focus on quality and management. Quality was again the focus of the organization's consistent ability to meet defined requirements, which ensure that customer requirements are clearly understood, defined, and met. It was the work of Technical Committee 176 that resulted in the publication of the original ISO 9000 series in 1987.

ISO 9000 is a term that refers to a group of international standards that are directed at the management process of an organization. 'ISO' means 'equal' in Greek. The International Organization for Standardization was founded in 1946 and is located in Geneva, Switzerland. This organization is made up of approximately 90 countries, including the USA.

To date, the ISO 9000 series of standards has been revised in 1994, 2000, and 2008. Normally, the goal is for revision every 5 years; however, due to the required extensive review process, this time frame usually exceeds a 5-year period. The original ISO 9000 certification series consisted of the following conformance standards:

ISO 9001: Quality Systems – Model for Quality Assurance in Design, Development, Production, Installation, and Servicing
ISO 9002: Quality Systems – Model for Quality Assurance in Production, Installation, and Servicing
ISO 9003: Quality Systems – Model for Quality Assurance in Final Inspection and Test

Manufacturing companies that performed design control (i.e., R&D) could choose to omit this process by becoming certified to ISO 9002; however, all choices were excluded with the elimination of ISO 9002 and 9003 with the release of ISO

9001:2000. As of this writing, the current version is ISO 9001:2008 and will be referred to as ISO 9001 from this point forward. Note: it is recommended that the reader review the current requirements per the ISO website.

The ISO 9001 quality management standard focuses on the existence, implementation, and effectiveness of a quality management system, not the individual product. The standard is generic in text and can be implemented by manufacturing and service organizations regardless of the type of product or service.

The first registration to an ISO 9000 standard in the USA happened in 1991. It was 1994 before a food manufacturing company actually achieved registration. In the years that followed, much of the food industry remained skeptical of the true advantage of developing systems compliant with this standard. Some of that concern related to the perceived extensive documentation requirements that were linked to the original standards and frankly, to ISO overall.

Related to additional system development history, it is interesting to note that basically, in the early years of compliance, those 'food' companies that chose to develop ISO 9000 compliant systems (ISO 9001, ISO 9002, ISO 9003) were in one of the following categories:

- Owned by an overseas company that required all of its sites to be registered.
- Registration was required to do business overseas. (Note: this did not affect food companies as much as it did other commodity type companies (i.e., electronics, automotive, etc.)).
- Top management identified and wanted to take advantage of the internal benefits experienced through compliance and registration.
- Top management identified and wanted to take advantage of the internal benefits of compliance applying these requirements to an internal program rather than to seek registration. In this instance, management understood the advantage of applying the requirements, but not the advantage of actually being registered.

Much of the initial concern from food industry-related sectors was related to the perceived extensive, unreasonable amounts of documentation requirements linked to the original ISO standards. However, this was not necessarily true and was reflected in the ISO 9001:2000 revision. The ISO 9001:2000 totally reorganized its requirements providing a stronger focus on defining, implementing, and managing a quality management system and focused more on measureable objectives, process application, and continuous improvement.

In discussing documentation, a good rule of thumb is 'as little as possible, but as much as necessary.' ISO 9001 actually only requires six documented procedures, which are *Internal Audits*, *Control of Nonconforming Product*, *Document Control*, *Record Control*, *Corrective Actions*, and *Preventive Actions*. Also, these requirements may be combined into one procedure that defines requirements for both such as combining corrective action and preventive action. The standard does state that these documents are required along with whatever other documents the organization feels are necessary for the structure and success of its system. Common sense and logic are very important when evaluating and deciding what actually must be defined in a documented procedure.

As previously stated, with the inception of ISO 9001:2000, food companies began to demonstrate more interest in developing a compliant system. ISO 9001 requirements were totally re-organized providing a stronger focus on defining, implementing, and managing a quality management system that focused on measurable objectives, process application, and continuous improvement.

The Management Responsibility section of ISO 9001:2000 provided a clear directive for top management of the organization to become involved and make decisions based on the effectiveness and suitability of the system, required resources, continuous improvement, and the system's ability to meet its defined 'measureable objectives.' Keep in mind that improvements are very difficult to track without structured 'measurements.'

Many food companies translated the requirements of ISO 9001:2000 into their own internal management system. Systems were defined, implemented, and monitored internally rather than seeking formal registration from a third party registrar. It was stated that meeting this structure and discipline through internal compliance resulted in considerable internal benefits to the company. The benefits from certification were many fold. The following information has been compiled from personal discussions with approved companies and also from independent market research surveys regarding the impact that ISO 9001 certification has had on doing business both internally and externally:

External benefits:

- External appraisal helped system.
- Enhanced marketing/advertising.
- Improved market share.
- Reduced customer audits.
- Increased competitiveness in international markets.

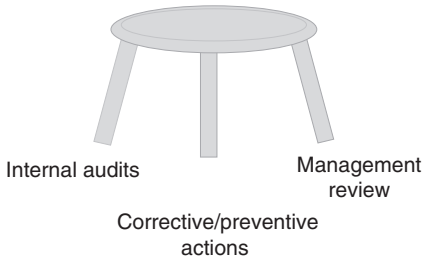
Internal benefits:

- Improved management control.
- Greater consistency.
- Cost reduction through reduced scrap and rework.
- Improved customer satisfaction.
- Identified 'nonvalue' activities.
- Improved efficiency and shortened time to market.
- Improved documentation and defined requirements.
- Improved staff motivation.
- Increased level of internal ownership and roles in the process.
- Structured communication between all levels.
- Enhanced teamwork and understanding of the 'internal customer'.
- Enhanced understanding of the 'team' approach.
- A system is a collection of processes within processes.

Whereas realizing external benefits depend heavily on the specific business and focused market, the internal benefits just make good business sense when applied effectively to an organization's complete system.

ISO 9001 is a management tool ,which, when integrated into a process, provides the foundation and structure through documentation and objective evidence that promotes consistency throughout the entire operation while focusing on

continuous improvement and meeting customer's needs and expectations. A well defined and formalized system clarifies management responsibility, policy statement, measureable objectives, and expected performance as the basis for its effective management system. Continuous improvement is inherent in the system, especially through effective processes from top management review meetings, internal audits, and corrective and preventive actions. This is demonstrated in the following diagram:



Effective processes for internal audits, corrective/preventive actions, and management review are essential for the development, maintenance and sustainability of every management system. If one leg of the above stool falters then the effectiveness of the whole management system is at risk.

As the reader reviews this initial section on ISO 9001, it is imperative to remain focused on the fact that this standard is the basis and foundation for almost every standard that has followed since its inception. Food Safety Management Standards, including a sampling of those Global Food Safety Initiative (GFSI)-recognized schemes, are discussed in subsequent sections of this article. It is important to remember that although focus may be on food safety, ISO 9001 'as the foundation' should always be recognized as the basic premise.

As previously stated, it is not necessary to reinvent processes to be compliant with the requirements of a management standard. Compliance is not a replacement! Existing Hazard Analysis Critical Control Point (HACCP), Good Manufacturing Practices (GMP), sanitation, pest control, and food hygiene programs must be integrated into the structured management system. This promotes adherence to defined procedures while enhancing programs through continuous improvement. Keep in mind that combining the focus of HACCP-based systems and management systems overall makes good sense. The HACCP program focuses on product safety whereas the management system focuses on the total system and those processes included in that system. A compliant structured management system such as one that meets the requirements of ISO 9001 provides the structure and discipline for which the HACCP program can be incorporated.

The requirements of an effective management system can be summarized in three major categories:

Plan the business: The organization's 'measureable' objectives and how the organization is structured to achieve them must be defined in the 'Quality Manual.' Specific elements define the implementation policy and the documented system required to control system activities.

Control the process: Specific elements focus the greatest emphasis on activities and controls related to providing a final product or service that meets defined requirements. These relate to both internal and external customer requirements.

Maintain the system: Once the system is implemented, specific element requirements address the maintenance of the system to ensure that it continues to operate effectively and is in compliance. The system is maintained for effectiveness through compliance with all elements and as stated previously, specifically through the processes for corrective/preventive actions, internal quality audits, and top management review. The overall functionality and status of the management system along with results from specific process activities must be evaluated by top management at the Management review meetings.

Management review meeting activities are planned and recorded to ensure and confirm that the policy statement, measurable system objectives, resources, and the system itself continue to be suitable and effective to the overall organization and its customers. Management review is the defined process for top management to manage, track, and ensure compliance and improvement of the management system. The overall purpose of a management review meeting is to evaluate the suitability, adequacy, and effectiveness of an organization's management system and to look for improvement opportunities. Management review meetings are performed at defined intervals in compliance with the specific quality and/or food safety standard. (ISO 9000, 9001, and 9004, Quality Management Definitions.)

The actual amount of resources (i.e., time, cost, etc.) and degree of difficulty necessary to bring a system into compliance depend on many elements including the size of the organization and its existing processes. Before beginning the project, it is important that those individuals responsible for guiding the organization through the implementation process receive competent education and training in the requirements. Earlier, it was stated that the standards are generic in nature and can be applied to any manufacturing process or service. This is true. It is essential that system leaders have an accurate understanding of how these requirements relate to their industry and more specifically, to their operation. Research, benchmarking, and acquiring the assistance of qualified individuals (i.e., consultants with credentials and experience in their industry) pay tremendous dividends in total cost, time, and employee motivation through all stages of system definition, implementation, and maintenance.

It is essential to evaluate existing processes and documentation to determine the extent to which these meet the requirements. System gaps can then be identified and addressed. Remember that processes must not be recreated or reengineered around the requirements; instead, the requirements should be integrated into the current system.

The question as to whether or not ISO 9001, as a management standard, fits the current world of food safety has been alluded to in the previous text. This is a question that is continually asked by top management of food companies of all sizes. Admittedly, as the food safety management system (FSMS) standards have evolved over the recent years, some companies that were ISO 9001 chose to drop their certification and replace it with a management system that focused only on food safety. Fortunately, at the time of this writing, these

companies are in the minority. The majority of ISO 9001-approved food companies have chosen to integrate the requirements for food safety into their current programs. Actually, most had already done this long before the FSMS concept was identified. After all, it is truly not possible to have quality without food safety. Actually, it has been found that it is quite difficult to define, implement, and maintain a FSMS that does not include 'quality' parameters. Some of the food safety management standards such as the current versions of Safe Quality Food (SQF) and British Retail Consortium (BRC) integrate food safety requirements with quality requirements. Many companies becoming certified to ISO 22000 and Food Safety System Certification (FSSC) 22000 have chosen to expand their management systems to include not only ISO 9001, but also ISO 14001 and OHSAS ISO 18001. 'ISO 14001 – Environmental Management' uses the same format as ISO 9001 and ISO 22000 in defining and ensuring compliance with environmental requirements. 'OHSAS 18001 – Occupational Health and Safety' applies the same format with focus on health and safety requirements.

Borrowing from the text *The ISO 9000 Quality System Applications in Food and Technology* (Newslow, Wiley C2001 US), the following applies to an effective management system:

- (Certification) promotes a system that anticipates and prevents problems rather than one that simply reacts.
- Builds quality in rather than inspects it in.
- Creates a platform by which a company can continuously evaluate and improve the business.
- Without a disciplined structure, a company may not have the complete tool set required to ensure proper resolution of business opportunities; without this commitment, many companies were basically departmentalized and primarily became a quality control department.
- Required system elements are exactly what many food companies in the US and abroad seek along with effective FSMSs such as HACCP, GMPs, sanitation programs, and other appropriate PRP programs.

FSMS Standards

When discussing food safety, it is critical to understand the terminology. The term 'food safety' is defined as the process of producing a food product that does not contain a food hazard when used according to its intended use when consumed. A 'food hazard' is defined as a biological, chemical, or physical agent either in the food or as a condition of the food that either results in or has the potential to cause an adverse health effect. Literature has many different versions of the above definitions, but most importantly, a food safety hazard is understood as those elements that could occur within the product or in the process; whereas, food security is an intentional act of sabotage focusing on causing harm. A 'safe' product is manufactured free of biological, chemical, or physical hazards that either have the potential to cause illness or other harmful outcomes on consumption of the product. Food safety hazards may occur at any stage in the food chain; thus, it is essential that sufficient controls are in place from 'farm to fork.' An effective food safety program of any kind must include effective controls and food safety commitment throughout the entire food chain.

Historically, it all began at the beginning of the twentieth century with the passage of the Federal Meat Inspection Act (FMIA) in 1906. Upton Sinclair's book *The Jungle*, which detailed significant food safety issues in meat packing facilities, had a direct impact on the passage of the FMIA. The Pure Food and Drug Act, which later became the Federal Food, Drug and Cosmetic Act, was enacted in the same era in US history.

The 'HACCP' concept was first introduced in the early 1960s by Dr. Howard Bauman when Pillsbury and NASA joined forces to produce a 'safe' product for the astronauts. HACCP guidelines are defined in Codex Alimentarius (2003) *Hazard analysis and critical control point (HACCP) system and guidelines for its application*. Monitor the Codex Alimentarius website for current requirements.

At the turn of the twenty-first century, we saw an emphasis on food safety in which regulatory agencies were requiring (or proposing) the HACCP process for what was considered high risk segments of the food industry (e.g., meats and poultry, seafood, 100% juice products).

On 4 January 2011, President Obama signed into law the FDA Food Safety Modernization Act (FSMA), which is the most encompassing reform of food safety laws in more than 70 years. This Act focuses its aim on ensuring that the US food supply is safe, applying prevention controls rather than responding to a contamination outbreak. The time has passed for the food industry to learn from its mistakes, now we must be proactive, not reactive. Effectiveness must be measured by evaluating our processes, products, ingredients, packaging materials, processing aids, and product contact surfaces using the eyes of prevention to identify existing and potential hazards, then putting actions in place that either eliminate or correct the situation. We must have confidence that we are producing a product that is safe for consumption. Every associate has the responsibility to ensure the production of a safe product taking every measure necessary to ensure this safety. It is time that top management seriously evaluates its processing system to define a proactive food safety program that identifies and ensures the control of existing and potential food safety hazards, based on current scientific principles, standards, and concerns.

As this article goes to press, because of the complexity of the FDA FSMA, the food industry in the USA is waiting for some rules to be clarified prior to the full scope of the law taking effect. In the meantime, consumers (above and beyond government laws) are demanding safe products. Food manufacturers are receiving extreme pressure from their customers to develop a proactive program that forces management its products, processes and suppliers to ensure that products are free of hazards and safe for consumption. In today's world of food safety, we define the word 'safe as a food that is free of any food hazards. 'Food safety' is defined as a finished product that does not contain a food hazard when used according to its intended use.

When one mentions the term 'HACCP', it reflects the process that is used to identify, prevent, evaluate, and control hazards, which are significant for food safety as defined in Codex Alimentarius. HACCP is a management tool designed to identify existing and potential hazards: biological pathogenic,

chemical, and physical in the ingredients and the process of the manufacturing of consumable goods from the farm to the table, establishing controls that reduce or eliminate risk for public health. HACCP provides the framework to produce foods safely and to prove they were produced safely. An effective HACCP program is built on the foundation of effective prerequisite programs.

Subsequent text describes many examples of currently accepted food safety management standards, also referred to as food safety management programs, but it is important to focus on the fact that an effective FSMS applies the concept of a structured management system as discussed earlier with the requirements of effective HACCP programs including requirements for specific prerequisite programs. Prerequisite programs (PRP) are defined as the, 'basic conditions and activities that are necessary to maintain a hygienic environment through the food chain suitable for the production, handling, and provision of safe end products and safe food for human consumption.' (ISO 22000:2005.) PRPs provide the foundation for the HACCP Program and address the basic conditions and activities required for food safety that are necessary to either control or eliminate a potential hazard, address a quality parameter, and/or maintain a hygienic environment throughout the operation.

In the past, some organizations have chosen to develop and maintain a system compliant with a third party food safety standard but not verified by an independent third party. It is recommended and, in many instances, required by the customers of the organizations, to have compliance confirmed and monitored by independent third party companies. This format adds additional discipline and removes some of the 'variances' that could be issued internally. It also builds consistency within the food chain sectors.

While food safety standards do have some differences and preferences for specific standards (in many instances, food sector specific), all focus on applying applicable FSMS requirements and evaluation of the system. The following sections provide an overview on GFSI and a brief description of each standard or program that has been benchmarked as an approved schemes meeting the current defined GFSI guidelines. Although specific websites are not referenced for the Individual FSMS, it is very important that the reader review these websites to receive current information. All the standards are revised on a defined schedule (some may even become obsolete through the years) making the individual websites the best source for current information and requirements.

GFSI is a nonprofit foundation established in May 2000, managed by The Consumer Goods Forum, and was launched in May 2000. The GFSI Foundation Board of Directors includes representatives from major global retailers, manufacturers, and food service operators that oversee basic management and direction.

This GFSI Foundation Board of Directors has developed a Guidance Document that outlines requirements that must be met by the Food Safety Management Standards that it recognizes. The GFSI Guidance Document is not a food safety management standard, nor does GFSI get involved in certification or accreditation activities. The GFSI Guidance document is reviewed by the Board at a minimum of once every 4 years; however, this may be more frequent based on current trends and issues as determined pertinent by the GFSI Board. Membership to the GFSI Board of Directors is by invitation only.

GFSI defines its vision to drive continuous improvement in food safety while strengthening consumer confidence worldwide with the primary focus of its objectives to:

- Reduce food safety risks by delivering equivalence and convergence between effective FSMSs.
- Manage cost in the global food system by eliminating redundancy and improving operational efficiency.
- Develop competencies and capacity building in food safety to create consistent and effective global food systems.
- Provide a unique international stakeholder platform for collaboration, knowledge exchange, and networking. (Quoted from http://www.mygfsi.com)

Through continuous improvement, GFSI provides a recognition process that can be used by food industry stakeholders; however, it is clearly stated in its documentation that it is each organization's choice as to which GFSI benchmarked scheme(s) is chosen. This decision may be based on the industry sector, company policy, customer requirements, customer needs, regulatory requirements, organization's preferences, and/or product liability.

The process for GFSI to review a FSMS standard confirming it meets the requirements of the most current version of the GFSI Guidelines is known as 'benchmarking.' In other words, 'benchmarking' is defined as a "procedure by which a food safety-related scheme is compared to the GFSI Guidance Document."

As previously mentioned, the GFSI board does not get involved in the actual certification process. Certification is achieved through a third party audit by an approved registration body against one of the recognized GFSI approved schemes.

Originally, four food safety standards (SQF, BRC, Dutch HACCP, and International Food Standard (IFS)) were recognized as GFSI schemes. In 2009, ISO 22000 in combination with PAS 220 (now known as ISO 22002-1) was benchmarked becoming the fifth recognized scheme. The standard representing the combination of ISO 22000 and PAS 220 became known as FSSC 22000. In subsequent years, additional food safety standards were benchmarked and confirmed compliant.

On 5 January 2011, GFSI released the Sixth Edition of its Guidance Document. On release of the Sixth Edition, all previously recognized standards were required to submit a request to be benchmarked in compliance with the GFSI Guidance Document Sixth Edition by 31 December 2011. The revised version of this guidance document provides more prescriptive and detail for identifying and providing clearer definitions required for the production of safe food in different industry sectors.

Industry sectors are divided into the following categories:

- Farming of Animals;
- All Farming of fish;
- B1 Farming of plants;
- B11 Farming of grains and pulses;

- C Animal conversion;
- D Pre-processing handling of plant products;
- E1 Processing of animal perishable products;
- E11 Processing of plant perishable products;
- E111 Processing of animal and plant perishable products (mixed products);
- EIV Processing of ambient stable products;
- L Production of (bio) chemicals;
- M Production of food packaging.

The revised version of this Guidance Document also provides an improved definition of the benchmarking process. This process is a scientifically based method that the GFSI board applies to identify competent food safety schemes. This approach allows food organizations to select the FSMS that best fits its needs and industry sector.

A brief description of the recognized schemes (May 2012) along with a brief description of the standard quoted from each website is provided in the text that follows; however, because this list may change at any time, it is recommended that the astute reader monitor the GFSI website for the most current information.

BRC Global Standard for Food Safety (sixth edition) is the current version at the time of publishing this article. The BRC Global Standards are widely used by suppliers and global retailers. They facilitate standardization of quality, safety, operational criteria, and manufacturers' fulfillment of legal obligations. This standard is designed to provide protection to the consumer. The BRC Global Standards are a leading global safety and quality certification program used throughout the world by over 17 000 certificated suppliers in 90 countries through a network of over 80 accredited and BRC-recognized Certification Bodies. (http://www.brcglobalstandards.com/GlobalStandards/Home.aspx)

CanadaGAP (Canadian Horticultural Council (CHC) On-Farm Food Safety (OFFS) Program): 'CanadaGAP (Good Agricultural Practices) is the name of the CHC's OFFS Program. The program consists of national food safety standards and a certification system for the safe production, storage, and packing of fresh fruits and vegetables.' (http://www.canadagap.ca/)

FSSC "FSSC 22000 (Food Safety Standard Certification) contains a complete certification scheme for FSMS based on existing standards for certification (ISO 22000, and ISO 22002-1 with latter technical specifications for sector PRPs)." Manufacturers that are already certified against ISO 22000 will only need an additional review against technical specifications for sector PRPs to meet this certification scheme. Organizations that want to integrate quality in their management systems follow the requirements of ISO 9001. FSSC 22000 is developed for the certification of food safety systems of manufacturers in the food chain that process or manufacture animal products, perishable vegetable products, those products with a long shelf life, (other) food ingredients like additives, vitamins, bio-cultures, and food packaging material manufacturing (quoted from http://www.fssc22000.com/en/).

Global Aquaculture Alliance "Seafood Processing Standard is an international, nonprofit trade association dedicated to advancing environmentally and socially responsible aquaculture. GAA recognizes that aquaculture is the only sustainable means of increasing seafood supply to meet the food needs of the world's growing population. Through the development of its Best Aquaculture Practices certification standards, GAA has become the leading standards-setting organization for aquaculture seafood." (Quoted from http://www.gaalliance.org/)

The GLOBALG.A.P. is a "private sector body that sets voluntary standards for the certification of production processes of agricultural (including aquaculture) products around the globe. (This standard) is primarily designed to reassure consumers about how food is produced on the farm by minimizing detrimental environmental impacts of farming operations, reducing the use of chemical inputs, and ensuring a responsible approach to worker health and safety as well as animal welfare. GLOBALG.A.P. serves as a practical manual for GAP anywhere in the world. The basis is an equal partnership of agricultural producers and retailers who wish to establish efficient certification standards and procedures." (Quoted from http://www.globalgap.org/)

Global Red Meat Standard (GRMS) is a scheme specifically developed for the meat industry. "Its cornerstone is product safety, focusing on critical areas affecting the maintenance of high meat safety requirements. The fact that GRMS has been specifically developed for the meat industry provides its customers with an invaluable tool for measuring a supplier's performance." (Quoted from http://www.grms.org/)

IFS Food Version 5 (International Featured Standard) includes "associated members of the German retail federation – Hauptverband des Deutschen Einzelhandels – and of its French counterpart – Fédération des Entreprises du Commerce et de la Distribution – drew up a quality and food safety standard for retailer branded food products, named the IFS Food, which is intended to allow the assessment of suppliers' food safety and quality systems, in accordance with a uniform approach. This Standard applies to all the postfarm gate stages of food processing." (Quoted from http://www.ifs-certification.com/)

PrimusGFS "is a private scheme that establishes requirements for the certification of products of the Agricultural sector in a voluntary manner at a world-wide level. The scope of PrimusGFS is focused on the food safety of those products of the agricultural sector designated to human consumption in their fresh or minimum processed way. PrimusGFS establishes a series of requirements for managing the production, handling, processing and storing operations, which should be met for consumer safety." (Quoted from http://www.primusgfs.com/)

SQF Edition 7 is a program that "provides two standards based on the type of food supplier: SQF 1000 for primary producers and SQF 2000 for manufacturers and distributors. Within these two standards, SQF helps make certification more attainable for smaller companies by dividing the process into three steps: from Level 1, which incorporates fundamental food safety controls appropriate for low-risk products all the way to Level 3, indicating a comprehensive implementation of food safety and quality management systems development." (Quoted from http://www.sqfi.com/)

Related to Dutch HACCP, The Foundation for Food Safety Certification, which also owns this standard, has stated that although the Dutch HACCP Standard was previously recognized against the GFSI Guidance Fifth Edition, it will not be resubmitted to GFSI for benchmarking to the GFSI Guidance

Document Sixth Edition. The stated intent is for the Foundation to focus on the management of the FSSC 22000 scheme, which they also own and which has been resubmitted for benchmarking. Dutch HACCP Option B certificates that were still in circulation in 2012 will be accepted as valid against the GFSI Guidance Document Fifth Edition during that year. However, any certificates issued after 1 January 2012 will not be considered to have been issued against a GFSI-recognized scheme.

Related to Synergy 22000, on 30 January 2012, the management of FSSC 22000 and of Synergy 22000 reached an agreement on a joint future strategy regarding the use of ISO 22000 as the basis for certification of FSMS in food supply chains worldwide. The cooperation will solve the user-unfriendly and confusing situation of having two equivalent schemes in the marketplace and generate synergies involving all available forces and competences behind a common objective within the FSSC framework.

The Food Safety and Quality Management System

This text has provided a comprehensive overview of both the quality management system standard from the ISO 9001 prospective and also the GFSI-approved FSMS schemes. The next step is for top management of the organization to make some critical decisions. One of the most important 'critical decisions,' if not the most important, focuses on management commitment and leadership and whether or not the organization is ready to make this journey. In many situations, organizations are finding that ready or not, their customers are making it a requirement for doing business.

Frank Yiannas, VP – Food Safety for Walmart in his book *Food Safety Culture Creating a Behavior-Based Food Safety Management System* (Springer, c2010, page 16) revisits the culture change or culture focus that must be in place in order for food safety programs to be the most effective. Mr. Yiannas states that "a food safety culture starts at the top and flows downward. It does not flow from the bottom up. It is a leadership function to create a food safety vision, set expectations, and inspire others to follow." Every standard mentioned previously addresses top management responsibility and commitment. Management commitment must also include food safety leadership. Mr. Yiannas points out that leadership and management are different. "The main difference between the two is that leadership is about influencing people to follow, while management focuses on maintaining systems and processes. Leading companies with strong safety cultures not only have strong FSMSs in place, they also have strong leaders committed to food safety who are able to influence others and lead the way to safer performance."

The development, implementation, and maintenance of a food safety and quality management system requires a serious commitment for success by the organization's management and entire associate team. Effective implementation requires resources. Resources may include adding additional staff and hiring an experienced consultant in both the standards of choice and in the organization's food sector. The initial focus must be on creating a system that is best for the organization, integrating the requirements into the existing operation in a manner that is not only compliant but adds value to the organization.

It is very important and cost effective long term to engage the assistance of a knowledgeable industry expert to assist the implementation team in training, identifying, and closing the gaps an organization may have in meeting the food safety management standard of choice. Once the implementation team is established, the most effective next step must be the performance of a gap analysis. It is recommended that this be done by an independent external consultant, or if you are part of a larger company with corporate resources, then possibly by a trained (in the standard of choice) company associate that is external to the operation. In many instances, the organization does not make decisions on standards or time tables for completion until after the gap analysis is completed. A favorite example is that a gap analysis is like taking an X-ray. It is absolutely foolish and ineffective to set a broken leg until an X-ray is taken. This is the same with the gap analysis. Evaluate the existing organization and its activities, identify the gaps, and assist in closing these gaps to achieve compliance. A gap analysis can be performed by the registrar of choice, but the auditor representing the registrar is limited on how much assistance he or she can provide in closing the gaps. This can be considered a conflict of interest because an auditor must not audit his/her own work. When choosing a consultant or auditor, be sure to confirm his/her experience in the standard of choice and also, if possible, in the organization's food sector.

The next critical discussion point is the resource issue. Resources must be appropriate for the organization's certification project plan. Based on experience, the absolute best and most effective process to address the resource issue is to empower the entire associate team. Many times, management has stated that they just did not have the resources to do what was needed, but some of these organizations had 200 plus associates. If every one of those associates spent 1 h a week assisting the implementation teams in writing, reviewing, and implementing the process, progress within the journey would be noted, the associates would feel part of the team, learning and enhancing individual knowledge on the system and its requirements. Documentation and other activities may move forward more efficiently because more individuals who have first-hand knowledge of the processes would be assisting the process and much more.

An effective, compliant food safety and quality management system is a system developed and implemented that is suitable and effective for the organization. As it matures, an effective system continues to add value while continually improving. Compliance and continuous improvement become a way of life. Most often, those who resist the most in the beginning become the biggest supporters. However, all that said, if the primary focus is just to get the certificate and to pass the audits then maintaining a compliant system becomes very difficult, draining resources without adding value. The confidence of producing a safe product becomes limited and from the quality aspect, meeting customer requirements also deteriorate. An effective food safety and quality management system is worth the effort and makes good business sense for every organization. A system patched together for a certificate or a quick fix to make the customer happy is like patching a life boat and trying not to sink. Eventually, the patches just quit keeping the boat afloat.

Conclusion

Personal experience has shown me that adhering to a structured management system such as ISO 9001, ISO 22000, ISO 14000, OHSAS 18001, SQF, BRC, or FSSC 22000 provides the structure and discipline necessary for a strong and efficient management system. A mature system provides the foundation for continuous improvement, improved quality performance, and increased profits while meeting the customer's needs and expectations. This structure and discipline makes good business sense. Jon Porter, a consultant specializing in food safety, summed it up perfectly by stating that "ISO is the envelope, and everything fits inside." This statement applies to compliance to a structured quality and/or FSMS such as those identified in this article.

Frequently asked questions are, 'How difficult is it to achieve registration?' and 'How much will this cost?' The answers are not simple. Each system is different. The initial step must be to identify and document existing processes, evaluating how each process meets the requirements, identifying the gaps, and then addressing them. It is critical that an operation does not reengineer its processes to meet the requirements, but as much as possible, integrates these requirements into its system. Related to cost, it is going to depend on the current resources and the defined project plan for the certification process. Cost can be measured strictly in dollars and cents or this plus overtime plus extended fixed costs. Based on experience, one of the most difficult questions to answer is how much will it cost. Personally, I have seen organizations spend ridiculous amounts of money and at the end have one of the worst systems ever developed, and on the flip side, management teams that provided leadership and structure defining a realistic project and time table with added cost measurable but justified based on the benefits and resulting value added system.

The point of this article has been to provide a brief description of ISO 9001, ISO 22000, and selection of benchmarked GFSI-recognized schemes related to food safety; however, it is important that the reader understands that these same concepts can and should apply to other management system standards and recognized schemes even those that may be company owned, defined, and audited for compliance internally. No matter which standard is chosen, most, if not all, have been developed and the requirements defined within the shadow of ISO 9001.

There is an abundance of information related to these standards in many different locations. It is truly up to the organization to determine which standard best fits its operation, food sector, and overall scope. Whichever standard is chosen, it remains critical that top management is committed to developing, implementing, and maintaining a management system that is not only effective and compliant, but also adds overall value to the organization. It is just as critical that resources are applied effectively and timely, based on the system's policy statement and its measureable objectives. Top management must understand, communicate, and support the development of the system including the assignment of resources in a manner that provides adequate opportunity for the development of an effective system. One of the greatest challenges may be trying to do too much too fast with inefficient resources. Even if success is achieved, sustainability often becomes difficult without continued strong and effective focus; without adequate support, such a system could self-destruct. Planning, assessing gaps, and whenever possible, integrating the requirements into the current system rather than reengineering will help to realize success along with promoting team work and communicating management support.

It is critical to focus on the positive through top management's leadership and commitment applying common sense to integrating the management system requirements into the operation. Remember the Deming PDCA (Plan, Do, Check, Act) concept. Set realistic, achievable objectives; identify the gaps, develop a plan, integrate, monitor, and apply resources effectively and efficiently. The road to compliance is not candy coated, but it is worth the effort. Russ Marchiando, production manager for Wixon, St. Francis, Wisconsin, described the certification process as "a journey, not a destination."

Good Practices in Fisheries and Aquaculture

L Ababouch, Food and Agriculture Organization of the United Nations, Rome, Italy

Glossary

Aquaculture The farming during part of the life cycle of finfish, crustaceans, and mollusks.

Capture fisheries It refers to all kinds of harvesting of naturally occurring living resources in both marine and freshwater environments.

Good aquaculture practices Those practices of the aquaculture sector that are necessary to produce quality and safe food products conforming to food laws and regulations.

Good hygienic practices All conditions and measures necessary to ensure the safety and suitability of food at all stages of the food chain.

Hazard analysis and critical control point (HACCP) A system that identifies, evaluates, and controls hazards that are significant for food safety.

Prerequisite program A program that is required before the application of the HACCP system to ensure that a fish- and shellfish-processing facility is operating according to the Codex Principles of Food Hygiene, the appropriate Code of Practice, and appropriate food safety legislation.

Introduction

World fish production from fisheries and aquaculture contributes significantly to global food security and food trade, with an average per capita supply of 18.6 kg (live weight equivalent) in 2010. World fish and seafood supply amounted to approximately 148 million tons of fish in 2010 (with a total value at harvest of US$217.5 billion), of which approximately 128 million tons were utilized for human consumption (Table 1).

Although production from wild fisheries has stagnated over the years at approximately 91–95 million tons, the increasing demand has been steadily met by a robust growth in aquaculture, estimated at an average 8.8% yearly growth in volume during the period 1980–2010, bringing the contribution of aquaculture to fish food supply to 47% in 2010 from a mere 9% in 1980. This trend is projected to continue, with the contribution of aquaculture to fish food supply estimated to reach 60% by 2020, if not before.

Table 1 World fisheries and aquaculture production and utilization

	2006	*2007*	*2008*	*2009*	*2010*	*2011*
Production (in million tons)						
Capture fisheries						
Inland	9.8	10	10.2	10.4	11.2	11.5
Marine	80.2	80.4	79.5	79.2	77.4	78.9
Total capture fisheries	90	90.3	89.7	89.6	88.6	90.4

 doi:10.1016/B978-0-12-378612-8.00343-7

Fish and seafood are highly perishable commodities. To prolong their shelf life and preserve their nutritional attributes, they are processed in a variety of ways. They are distributed either live, fresh, chilled, frozen, heat treated, fermented, dried, smoked, salted, canned, or as a combination of two or more of these (Figure 1). Utilization of live/fresh fish and seafood has increased over the years more significantly than the other forms of preservation.

Likewise, fish and fishery products are among the most traded food commodity worldwide. The total world fish trade increased significantly from US$8 billion in 1976 to a record export value of US$109 billion in 2010. A specific feature of fish trade is the wide range of product types and participants. In 2010, 205 countries reported exports of fish and fishery products, of which 89 were net exporters, with a significant contribution of the sector to their national economies. More than 67% of the traded seafood is imported by three major markets: the European Union (EU), Japan, and the USA. These three markets are characterized by stringent and exacting requirements for consumer protection and food safety.

This article provides an update on the major fish and seafood safety issues and how to address them by developing and implementing reliable food safety and quality systems. Many academic and industry publications have been devoted to this area during the past 20 years. These works have been extensively used by Food and Agriculture Organization of the United Nations (FAO), World Health Organization, and Codex to develop an international guidance that is practical and adaptable to both developed and developing countries. This article draws on this extensive international work, in particular on the FAO flagship publication on the subject and other international initiatives by the Codex and national food control authorities to provide the reader with a practical guidance on fish and seafood safety issues and how to manage them from harvest to distribution.

Fish- and Seafoodborne Illnesses and Causative Agents

When harvested in clean environments and handled hygienically, fish and seafood are very safe. Unfortunately, water pollution, unhygienic practices, and insufficient or delayed icing or refrigeration have been the cause for many outbreaks of fish- and seafoodborne illnesses (Table 2).

Many of these causative agents are also responsible for illnesses caused by other types of food, especially food of animal origin. They are described elsewhere in this encyclopedia, including their ecology and association with foods. Following is a brief description of these agents.

Bacteria

Apart from *Vibrio* spp., *Listeria monocytogenes*, and *Clostridium botulinum*, which are part of the indigenous fish flora, the other bacteria that can contaminate fish and cause the majority of fishborne illnesses may come from the environment, the handlers, water used for washing the fish, or ice. Bacteria that are indigenous to the aquatic and the general environment may be associated with fish at the primary production stage (aquaculture or fish harvesting) and those derived from the general environment or from animal/human reservoir may be introduced as a result of contamination of the water or during handling and processing of fish. In either case, the initial levels of the bacteria are generally low and multiplication of the organism in fish to reach an infective dose or to produce toxin in fish precedes fishborne illnesses. Therefore, for management of the risk due to these pathogens, preventing their growth using refrigeration, freezing, or other preservation techniques is very important.

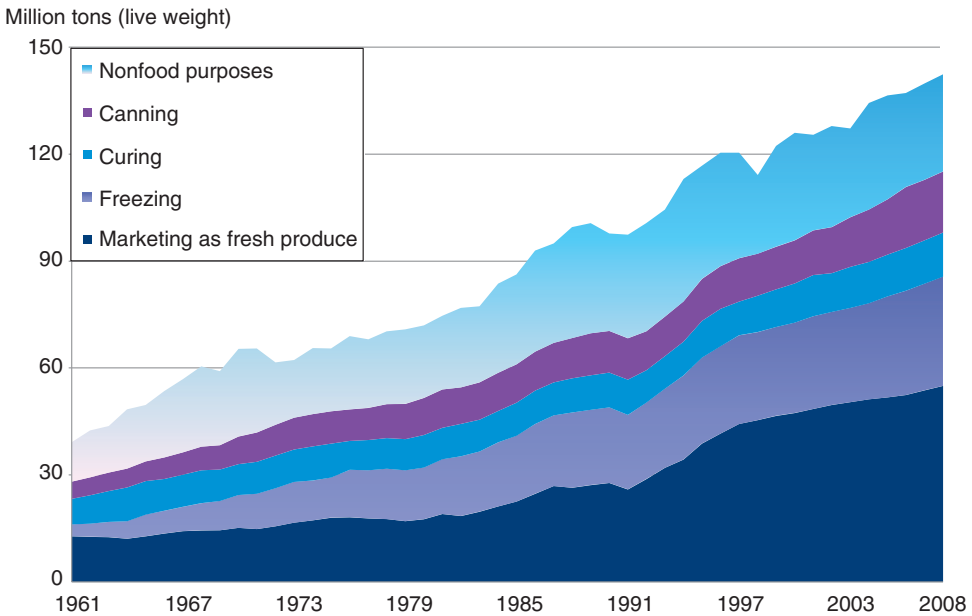

Figure 1 Fish and seafood utilization (1961–2008), in volume.

Table 2 Types of fish- and seafoodborne illnesses

Types of illness		*Causative agent*
Infections	Bacterial infections	*Listeria monocytogenes*, *Salmonella* spp., *Escherichia coli*, *Vibrio vulnificus*, *Shigella* spp., and *Vibrio cholerae*
	Viral infections	Hepatitis A, norovirus, and hepatitis E
	Parasitic infections	Nematodes (roundworms), cestodes (tapeworms), and trematodes (flukes)
Intoxications	Microbial	*Staphylococcus aureus*, *Clostridium botulinum*, and histamine
	Biotoxins	Ciguatera, paralytic shellfish poisoning, diarrheic shellfish poisoning, amnesic shellfish poisoning, and neurotoxic shellfish poisoning
	Chemical	Heavy metals: mercury, cadmium, and lead
		Dioxins and polychlorinated biphenyls
		Additives: nitrites and sulfites

Biotoxins

Biotoxins or phycotoxins are marine toxins that accumulate in fish or bivalve mollusks (mussels, oysters, scallops, clams, etc.). Most of these toxins are produced by species of naturally occurring marine algae (phytoplankton). There are approximately 5000 species of marine algae, but only 70–80 species are known to produce toxins. A proportion of the toxic phytoplankton has a red-brown pigmentation, the reason why the algal blooms are named 'red tides.' However, not all colored algae are toxic and incidences of poisoning have occurred in the absence of red tides. Bivalve mollusks are filter feeders and continually pump water through their gills for feeding by removing and ingesting particulate matter. During a bloom, bivalves can accumulate sufficient toxin to cause human illness after filter feeding for only 24 h. Biotoxins have been responsible for incidents of large-scale death of sea life and are increasingly responsible for human intoxication. Seafood poisoning syndromes associated with toxic marine algae are paralytic shellfish poisoning, amnesic shellfish poisoning, diarrheic shellfish poisoning, neurotoxic shellfish poisoning, and azaspiracid shellfish poisoning. Other types of biotoxins associated with finfish include ciguatera fish poisoning and puffer fish poisoning.

Histamine Fish Poisoning (HFP)

HFP is an intoxication that can be caused by consumption of many different types of marine finfish that contain toxic levels of histamine. HFP commonly occurs worldwide. Many species of marine finfish have caused HFP, and the intoxication is often referred to as scombroid or scombrotoxin poisoning because of the frequent association of the illness with the consumption of scombroid fish such as tuna, skipjack, saury, and mackerel. However, nonscombroid fish such as anchovies, bluefish, herring, mahi-mahi, marlin, sardines, and swordfish have also been implicated in outbreaks of this illness. These fish species have significant amounts of histidine in their muscle tissues where it serves as a substrate for bacterial histidine decarboxylase and formation of histamine. Consequently, to reduce HFP, preservation techniques to reduce growth and activity of histamine-producing bacteria should be applied.

Viruses

Foodborne viruses are derived from the human gastrointestinal tract, and their presence in water and food is a result of contamination with sewage, poor hygiene, or contamination by food handlers. Viral diseases are associated mainly with bivalves because they feed by filtering large amount of water, which causes the viruses to concentrate when the harvesting water is contaminated. Though a number of viral groups have been detected in bivalves, clear epidemiological links with seafood exist only for norovirus and hepatitis A virus. Astrovirus has also been reported as an etiological agent in a limited number of shellfish-associated outbreaks.

Chemical Contaminants

The main chemical contaminants of concern in fisheries and aquaculture are heavy metals (mercury, cadmium, and lead); organic pollutants such as dioxins and polychlorinated biphenyls (PCBs); and antimicrobial substances including veterinary drugs and additives such as metabisulfites. Some of these substances have maximum regulatory limits (MRLs), whereas others are banned or should have no residues. MRLs are defined for authorized veterinary drugs, antibiotics, additives, and certain contaminants that are already part of the environmental background.

Many organic pollutants were considered useful products before their negative impact on the environment and biota was noticed. These include herbicides and pesticides for agriculture, and PCBs, which have been used as additives and fire retardants in a range of consumer and commercial products such as electronics or textiles. Some other compounds like dioxins are by-products of certain industrial processes (e.g., metallurgical industry) and combustion processes like waste incineration, or during natural processes like forest fires or volcanic eruptions.

Heavy metals are naturally present in the aquatic environment and in its biota due to volcanoes, geological anomalies, and geothermal events, but anthropogenic pollution results from various industrial activities. The distribution between the natural background concentration of heavy metals and anthropogenic heavy metals in fish varies, depending on the element, the species, and the area of

capture. In open seas, which are much less affected by pollution, fish carry mostly the natural burden of heavy metals. In moderate or heavily polluted areas such as those that do not have sufficient exchange with the world oceans (e.g., Baltic sea and Mediterranean sea), in estuaries, in rivers and lakes, and especially in places in close vicinity to industrial activities, heavy metal concentrations actually found in seafood can exceed the natural concentrations.

There is evidence that some antibacterials are used as prophylactics and growth promoters in aquaculture. This can result in

- the presence of high levels of residues of approved antibiotics and/or residues of unapproved or banned antibiotics and
- the development of resistance to antibiotics in microbial pathogens in the environment.

Of major concern in aquaculture are residues of chloramphenicol, nitrofurans, and malachite green. Their use in food production is banned by many countries.

Proper selection of aquaculture sites and periodic monitoring of fishing and aquaculture water for potential chemical contaminants should assure appropriate consumer protection. The presence of residues of antimicrobials over approved MRLs could be eliminated through applying good management practices, hazard analysis and critical control point (HACCP) procedures, education, and awareness building.

Parasites

Fishborne zoonotic parasites are prevalent in many regions of the world and are among the most important of all zoonotic parasites infecting humans. The number of people currently infected with these parasites may exceed 20–30 million, with the number of people at risk worldwide estimated at more than half a billion. Fishborne parasites include species of nematodes (roundworms), cestodes (tapeworms), and trematodes (flukes). They are found in both marine/brackish and freshwater wild and cultured fish. In all the important species, a larval stage present in the fish host is transmitted to a suitable final host, in which full development to the reproducing adult stage occurs. For some parasite species, however, the larval stage does not mature in the human host (i.e., the nematodes *Anisakis* and *Gnathostoma*), but remain in a larval stage that can migrate through the host's tissues causing pathological damage. Importantly, fishborne parasite infections in people often exist as a multiple species complex, because they have common transmission modes that are favored by well-entrenched cultural traits, particularly fondness for raw or lightly cooked, cured, or pickled fish and fish products.

Physical Contaminants

Finally, physical contaminants such as glass, metal and wood pieces, nails, bones in fish fillets, hooks, etc. have also been at the origin of consumer health distress and need to be considered when designing a seafood safety assurance program.

Fish and Seafood Safety and Quality Systems

Robust safety and quality assurance systems that build on good practices are necessary to prevent and control fish- and seafoodborne illnesses. These systems and practices aim at preventing the contamination of fish, crustaceans, and shellfish during harvesting, landing, handling, processing, and distribution and preventing microbial growth after harvesting. Figure 2 describes the main hazards and the main elements of an assurance system for the three major fish and seafood value chains.

Depending on the fish or seafood species, the prevention requires monitoring the harvesting grounds, implementing GAPs and good hygienic, and handling and manufacturing practices during the postharvest stages. Government authorities have the primary responsibility for implementing robust monitoring programs, whereas the industry has the primary responsibility for implementing good practices in aquaculture and during the postharvest stages, using HACCP-based programs where applicable. In the latter, government authorities are responsible for certifying that good practices are adhered to on board fishing vessels, in fish farms, and during processing and distribution.

Monitoring of the Harvesting Grounds

Fishing should be carried out only in clean waters. Regular monitoring of the water quality is key in assessing whether the area is suitable for harvesting fish, crustaceans, or bivalves for human consumption.

Open seas are unaffected by pollution, and the finfish and crustaceans harvested in these areas are generally clean and fit for human consumption. Monitoring programs are required for some freshwater, estuaries, and coastal waters contaminated by sewage, or where shoreside industries are located or intensive agriculture using pesticides or other agrochemicals is practiced. These monitoring programs are generally enacted through regulations that define responsibilities and resources to food control authorities that will manage the monitoring programs, although research and industry are also involved. Environmental monitoring can identify species susceptible to contamination, magnitude of contamination, and spatial distribution of contamination. For example, the US Environmental Protection Agency has developed guidance for assessing chemical contaminant data for use in fish advisories. This would be a very useful guide for the development of a national fish contaminant-monitoring plan in other countries. Likewise, in the EU regulations, monitoring fishing and aquaculture areas for environmental contaminants has been included as a part of the regulatory food safety management. A guide for the establishment of environmental- and residue-monitoring plans for compliance with EU regulations has been developed for use by countries exporting fish to the EU. The development of a sampling and analysis plan by a team consisting of the food control authority, research, and industry should be based on the knowledge of the fishery and the likely sources of contamination. When contaminants above permissible limits are found, it is necessary to

- trace the source of contamination;

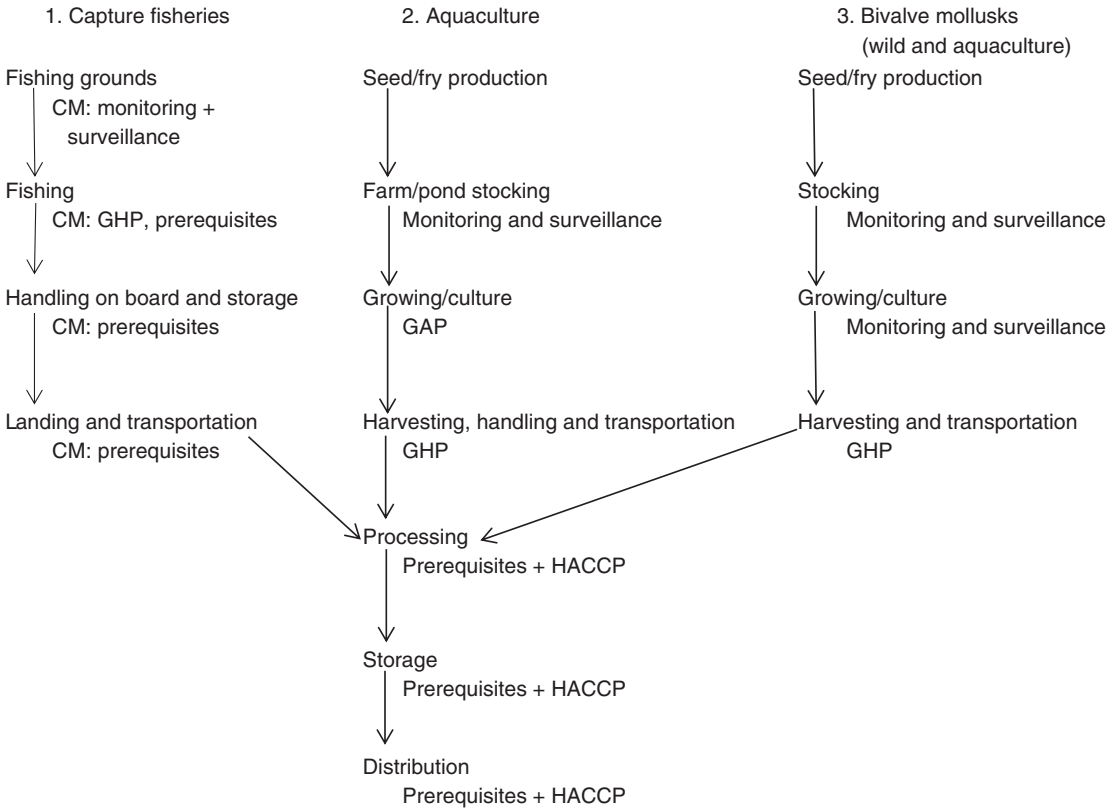

Figure 2 Fish and seafood safety management in fisheries and aquaculture. CM, control measures; GAPs, good aquaculture practices; GHPs, good hygienic practices.

- define the affected area and map the boundaries;
- suspend fishing in affected areas; and
- review the status with further sampling and analysis.

Monitoring and surveillance programs are also required for areas where bivalve mollusks are grown. The main hazards associated with the production of bivalve mollusks are contamination by bacteria, viruses, or biotoxins from the harvesting waters.

The identification, classification, and monitoring of these areas is a responsibility for the competent authority (CA) having jurisdiction, in cooperation with fishermen and primary producers. *Escherichia coli*/fecal coliforms or total coliforms may be used as an indicator for the possibility of fecal contamination. The results of the microbiological analysis would enable the CA to classify the growing areas as either

- suitable for harvesting bivalves for direct human consumption;
- relaying the harvested bivalves in acceptable water (relaying is the removal of bivalve mollusks from a microbiologically contaminated growing area to an acceptable growing or holding area under the supervision of the CA and holding them there for the time necessary for the reduction of contamination to an acceptable level for human consumption);
- depuration of the harvested bivalves in an approved depuration center (depuration is the reduction of microorganisms to a level acceptable for human consumption by the process of holding live bivalve mollusks for a period of time under approved, controlled conditions in natural or artificial seawater suitable for the process, which may be treated or untreated);
- approved processing to reduce microbial contamination to acceptable level; or
- unsuitable for growing or harvesting bivalve mollusks.

When sampling shellfish meats for classification purposes, if the limits of any biological or chemical hazard set in the end product specification are exceeded, appropriate measures must be taken under the responsibility of the CA. If biotoxins are found in the bivalve mollusks flesh in hazardous amounts, the growing area must be closed for harvesting bivalve mollusks until toxicological investigation shows that the bivalve mollusk's meat is free from hazardous amounts of biotoxins. Harmful chemical substances should not be present in the edible part in such amounts that the calculated dietary intake exceeds the permissible daily intake.

GAPs

Assurance of fish and seafood safety and quality in aquaculture requires the adoption and implementation of GAPs as prerequisites for the implementation of the HACCP system. The following good practices apply to the various aquaculture systems of finfish and crustaceans. The main stages of aquaculture production covered are site selection; growing water

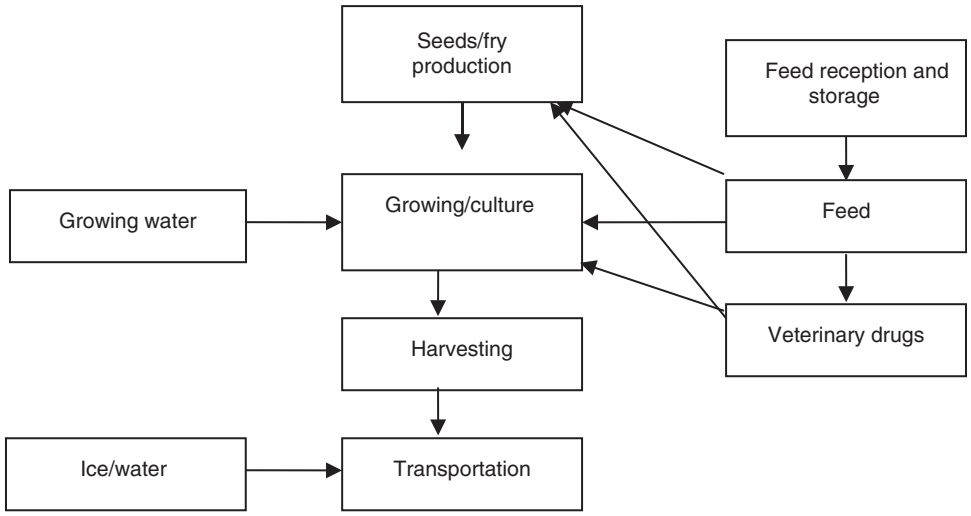

Figure 3 Example of a flow chart for aquaculture (only for illustrative purpose; Codex Alimentarius Commission (CAC) (2009) *Guidelines for the Design and Implementation of National Regulatory Food Safety Assurance Programmes Associated with the use of Veterinary Drugs in Food Producing Animals (CAC/GL 71-2009)*, 32 pp. Rome: FAO).

quality; source of fry and fingerlings; feeding; growing; and harvesting and transport (Figure 3).

Site Selection

Food safety hazards can arise from the location of the fish farm as a result of its surroundings, through the water supply, direct contact with livestock or wild animals, or airborne contamination (i.e., chemical sprays). Nearby agricultural lands that use pesticides and heavy fertilization on a regular basis could be a potential source of contamination. Fish farms should be located in areas where the risk of contamination by biological, chemical, or physical food safety hazards is minimal and where sources of pollution can be controlled. All potential sources of contamination from the environment should be considered. In particular, fish farming should not be carried out in areas where the presence of potentially harmful substances would lead to unacceptable levels of such substances in fish.

Growing Water

The water in which fish is raised should be suitable for the production of food that is safe for human consumption. Fish farms should not be sited where there is a risk of contamination of the water in which fish are reared by chemical and biological hazards. Water sources should be protected from contamination by wild (birds, lizards, snakes, turtles, and rats) and domestic (cattle, pig, chicken, ducks, cats, and dogs) animals, effluents, and runoffs. Fish farms should be designed and constructed to ensure control of hazards and prevention of water contamination. Water inlets and outlets to ponds should be screened to prevent the entrance of unwanted species. Water quality should be monitored regularly to prevent fish contamination during production.

Source of Fry and Fingerlings

The source of postlarvae, fries and fingerlings should be controlled in order to avoid the carryover of potential hazards into the growing stocks. In endemic fishborne parasitic areas, the source of fries and fingerlings should be controlled to assure that seeds are free from parasitic infection. Contaminated sources are common in endemic trematodiasis areas.

Feed Supply

Feeds can transmit harmful agents directly or by attracting pests. Feed ingredients should not contain unsafe levels of pesticides, chemical contaminants, microbial toxins, or other adulterated substances. Feed should contain only such additives, growth-promoting substances, fish flesh-coloring agents, antioxidizing agents, caking agents, or veterinary drugs that are permitted for fish by the CA. Industrially produced feeds and feed ingredients should be properly labeled. Their composition must fit the declaration on the label.

Medicated feeds should be clearly identified in the package and stored separately, in order to avoid errors. Dry fish feeds should be stored in cool and protected dry areas to prevent contamination, mold growth, and spoilage. Moist feed or feed ingredients should be properly refrigerated and should reach the fish farm in an adequate state of freshness. Fish silage, trash fish, and offal from fish, if used, and where necessary, should be properly cooked or treated to eliminate potential hazards to human health.

Veterinary Drugs

All veterinary drugs for use in fish farming should comply with national regulations and international guidelines, in accordance with the Codex guidelines on the use of veterinary drugs in food-producing animals (CAC/GL 71-2009). Drugs used on the farm should be registered with the appropriate national authority.

Control of diseases with drugs should be carried out only on the basis of an accurate diagnosis. Drugs should be prescribed or distributed only by personnel authorized under national regulations and should be used according to the manufacturer's instructions, with particular attention to

withdrawal periods. Records should be maintained when veterinary drugs are used.

Growing

The growing phase includes various activities that can significantly affect the safety and quality of farmed fish. There is a need to control the growing water quality, the design and cleaning of equipment and holding facilities, the maintenance of pond grounds, the workers' hygienic practices, and pests.

Good maintenance of the farm grounds and GHPs in the growing area and surroundings should be applied to minimize or eliminate facal contamination of pond water. A major concern is the contamination by pathogenic bacteria or parasites from waste materials or facal matter from animals or workers. Fish farms should institute a pest-control program. Good water quality should be maintained by using stocking and feeding rates that do not exceed the carrying capacity of the aquaculture system. Stocking densities should be based on culture techniques, fish species, size and age, carrying capacity of the fish farm, anticipated survival, and desired size at harvesting. Diseased fish should be quarantined when necessary, and appropriate and dead fish should be disposed of immediately in a sanitary manner.

Harvesting, Holding, and Transportation

Appropriate harvesting techniques should be applied to minimize spoilage, physical damage, and stress in the case of live fish. Harvesting should be rapid so that fish are not exposed unduly to high temperatures. In tropical areas, harvesting should be done at a time when temperature is lowest (e.g., at night). Soon after harvest, fish should be washed using clean seawater or freshwater under suitable pressure to remove excessive mud and weed and be iced or immersed in ice slurry to bring and maintain its temperature to approximately 0 °C. Equipment and utensils such as nets, bags, pumps, baskets, tubs, bins, and boxes should be designed and constructed to ensure minimum physical damage of the fish during harvesting. All equipment and utensils used during harvesting should be easy to clean and to disinfect and should be cleaned and disinfected regularly and as appropriate. Ice should be made from clean potable water.

Holding and transportation should be rapid so that fish are not exposed unduly to undesirable high temperatures. Fish should be packed in ice or immersed in ice slush aiming at keeping the temperature as closer as possible to 0 °C. All equipment for fish holding and transportation should be easy to clean and to disinfect and should be done so regularly as appropriate. Live fish should be handled in such a way as to avoid unnecessary stress. Records for transport of fish should be maintained to ensure full product tracing.

Good Practices and HACCP in Postharvest Operations

Prerequisite Programs

As stated in the Section Fish- and Seafoodborne Illnesses and Causative Agents, several pathogens and spoilage bacteria can contaminate fish and seafood during handling, processing, or distribution, either from handlers, equipment, surrounding environment, or other sources such as cleaning water or ice. To prevent this contamination from taking place, GHPs should be applied at all stages of harvesting, processing, storage, and distribution. The requirements for hygienic practices constitute the prerequisite programs that are essential for any fish and seafood operation before the implementation of HACCP.

The basis for developing and implementing GHPs are the 'Codex CoP on food hygiene (CAC/RCP 1-1969, Revision 2003)' and the 'CoP for fish and fishery products (CAC/RCP 52-2003, Revision 2009).' The provisions of these two CoPs have been used by most countries as the basis for their fish and seafood hygiene regulations, and by most fish and seafood trade associations and companies worldwide for drafting their food safety and quality policy.

A prerequisite program should include hygienic requirements for

- fishing vessel design and construction,
- processing facility design and construction,
- design and construction of equipment and utensils,
- hygiene control program,
- personal hygiene and health,
- transportation,
- product tracing and recall procedures, and
- training.

For example, the Food and Drug Administration (FDA) regulations of 2011 requires processors to have key sanitary conditions written into sanitation standard operating procedures, to monitor these conditions and practices, to correct unsanitary conditions and practices in a timely manner, and to maintain sanitation control records.

Likewise, the European Commission's 'hygiene package' addresses the prerequisite requirements both in 'horizontal' legislation and 'vertical' or commodity-specific legislation laying down specific hygiene rules for food of animal origin, including fish and fishery products.

HACCP Principles and Their Application

The HACCP is a system that identifies, evaluates, and controls hazards that are significant for food safety. It is a science-based and systematic tool that assesses hazards and establishes control systems that focus on prevention rather than relying mainly on end product testing. It not only has the advantage of enhancing the safety of the product but, because of the means of documentation and control, also provides a way for demonstrating competence to customers and compliance with legislative requirements to the food control authorities.

HACCP has been in a constant state of evolution for the past 40 years. Implementation by the fish industry has been slow and at times painful – a process that is still in progress. Application guidelines, prerequisite programs, decision trees, and training programs have been developed and implemented. Coalition of fish and seafood industries, such as the US Seafood HACCP Alliance or the Seafood Services Australia have been formed to train and certify HACCP trainers, and develop hazard analysis and generic HACCP guidance and plans. The author has also described through examples from the fish industry how an HACCP plan can be developed and implemented. The interested reader is encouraged to study

these examples to learn and practice the development of HACCP plans.

Currently, most national food control agencies and international institutions have adopted regulations, guidelines, codes, and procedures for the development and implementation of HACCP plans by the fish industry. As a consequence of HACCP becoming the food safety regulatory system of choice, policy issues have been shaping its evolution, sometimes more than science. For the future, it is important to ensure that food safety policy frameworks maintain the science basis at the heart of HACCP development to embrace future technological developments and the food safety challenges they will bring along.

HACCP can be used to deal with both safety and quality issues, although some regulatory agencies, such as the FDA, have confined it only to safety aspects. Experts in food microbiology argue that given that many control measures (e.g., hygiene, refrigeration, use of ice, thermal treatment, etc.) actually prevent the growth of microorganisms of concern to both safety and quality, it is advisable to use HACCP to address both aspects. The additional burden is related to further recordkeeping and documentation to address both safety and quality, and consequently the additional time and human power needed to verify and audit these records by the food control authorities. The Codex Code of Practice for Fish and Fishery Products in chap. 5 recommends and addresses both safety CCPs and quality defect action points.

In aquaculture, the application of GAP is effective for preventing and controlling most, if not all, food safety and quality hazards at the farm. That is why many regulatory authorities emphasize that mandatory implementation of GAP is sufficient for operating fish farms to supply safe and quality fish. However, many experts and the Codex stress that integration of GAP into HACCP-based systems at the farm level leads to improved cost effectiveness and real-time prevention and control of hazards. Although most control measures and critical limits are well specified in regulatory GAP, additional requirements such as hazard analysis, identification of corrective actions, monitoring, and HACCP verification allow the aquaculture farm to take ownership of its fish safety and quality program, respond in real time to safety challenges, and develop recordkeeping and traceability trails necessary for government or private audit and certification. In addition to being doable and cost effective, the application of HACCP in aquaculture complements effectively biosecurity measures taken to prevent fish diseases. Currently, in several countries around the world, an increasing number of aquaculture farms are applying HACCP-based concepts to control food safety issues. The challenge for small-scale farmers is being tackled in many countries such as India, Thailand, Vietnam, and Indonesia, by organizing the farmers into clusters or self-help group, which enables farmers/farms in the group/cluster to reach a size suitable for the application of GAP and HACCP with technical support from specialized extension institutions.

Training

Practical training in prerequisites, GHP, GAP, and HACCP is fundamental for operating good safety and quality assurance programs in fisheries and aquaculture. All personnel should be aware of their role and responsibility in protecting fish and seafood from contamination and deterioration. Handlers should have the necessary knowledge and skill to enable them to handle fish hygienically. Those who handle strong cleaning chemicals or other potentially hazardous chemicals should be instructed in safe handling techniques.

Each fish and seafood facility should ensure that individuals have received adequate and appropriate training in the design and proper application of an HACCP system and process control. Training of personnel in the use of HACCP is fundamental to the successful implementation and delivery of the program in fish or seafood production, handling, processing, and distribution. Managers should also arrange for adequate and periodic training of relevant employees in the facility so that they understand the principles involved in GHP, GAP, prerequisites, and HACCP. Periodic assessment of the effectiveness of training and instruction programs should be made, as well as routine supervision and checks to ensure that procedures are being carried out effectively.

Traceability

The fundamental and practical aspects of the role of traceability in food safety is discussed elsewhere in this encyclopedia, other publications and in the food legislation of countries that are major traders in fish and seafood. It is worth highlighting that traceability in the complex fisheries and aquaculture chains must be an essential component of a fish and seafood safety management system to ensure that each stakeholder in the value chain is well informed of the origin of the fish (harvesting area, aquaculture farm); its handling, processing, and distribution chain; and the control measures it has undergone.

Conclusion

The globalization of world fish trade offers many benefits and opportunities to countries, companies, and consumers. At the same time, it presents emerging safety and quality challenges. Major improvements have been achieved in this area, especially with the wide use of GHP, GAP, and HACCP. However, improved scientific tools must be adopted and novel approaches to fish safety must be sought so that regulatory actions can reflect the most current scientific evidence and that responsibility for safety is effectively shared among stakeholders along the fish and seafood value chain.

FOOD SAFETY ASSURANCE SYSTEMS

Good Animal Husbandry Practice

KN Bhilegaonkar, S Rawat, and RK Agarwal, Indian Veterinary Research Institute, Bareilly, India

Glossary

Feed Any single or multiple materials, whether processed, semiprocessed or raw, which are intended to be fed directly to food-producing animals.

Food safety Assurance that food will not cause harm to the consumer when it is prepared and/or eaten according to its intended use.

Good animal husbandry practices Good animal husbandry practices (GAHP) are guidelines that need to be adopted at the level of the primary producer to ensure production of food of animal origin that is safe for human consumption and acceptable for trade in the world market.

Hazards A biological, chemical, or physical agents in, or a condition of, an animal or animal product with the potential to cause an adverse health effect.

Incidence The number of new cases or outbreaks of a disease that occurs in a population at risk in a particular geographical area within a defined time interval.

Maximum residual limit for veterinary drugs (MRLVD) The maximum concentration of residue resulting from the use of a veterinary drug (expressed in mg kg^{-1} or μg kg^{-1} on a fresh weight basis) that is recommended by the Codex Alimentarius Commission to be legally permitted or recognized as acceptable in or on a food.

Residue The parent compounds and/or their metabolites in any edible portion of the animal product, and include veterinary drug, pesticides, or heavy metals.

Traceability The ability to trace and follow a food, feed, food-producing animal, or substance intended to be, or expected to be, incorporated into a food or feed, through all stages of production, processing and distribution.

Withdrawal period or withholding time Is the period of time between the last administration of a drug and the collection of edible tissue or products from a treated animal that ensures the contents of residues in food comply with the maximum residue limit for the veterinary drug (MRLVD).

Zoonoses Any disease or infection that is naturally transmitted from animal to man and *vice versa*.

Introduction

Animal food products such as meat, milk, and eggs, which form important component of human diet, are susceptible to contamination by potentially harmful microorganisms or chemical hazards such as residues of drugs, pesticides, and heavy metals along the food chain right from production at farm to the final consumption. This has lead to many food-borne outbreaks leading to great economic losses due to food recall and destruction of large number of livestock in addition to human illness. For instance during the bovine spongiform encephalopathy (BSE) scare in the UK and the highly pathogenic avian influenza (HPAI) outbreak in the Asian subcontinent, mass culling was adopted to contain the infection leading to economic losses running in billions of dollars.

The need today is for food that is not only safe but also perceived to be safe by consumers. The most important place to control any hazardous substance from entering the food chain is at the level of the primary producer. Animals may become a reservoir of potentially harmful chemicals like drug residues, pesticides and microorganisms due to disease contracted in their life or due to feed or water that is ingested at the farm. These harmful substances in turn enter animal food products and pose a threat to human health. A single infected animal can also contaminate the milk and meat of other healthy animals at the time of processing, thus the most important control in animal production can be exercised at the initial farm level. The increase in demand of the consumer for safe and morally acceptable food and stringent norms adopted by the Codex Alimentarius Commission have lead the World Organisation for Animal Health (OIE) and Food and Agriculture Organization of the United Nations (FAO) to frame guidelines that would help the livestock farmers to raise animals that are healthy and fit for trade in the international market. In the wake of globalization of the animal food product industry, pressure is on the primary producers to raise animals on the basis of risk analysis and control of these risks through the adoption of the good animal husbandry practices (GAHP). The present approach is based on control not by means of meat inspection but prevention by risk analysis and control throughout the production cycle, especially at the farm level. GAHP are guidelines that need to be adopted at the level of the primary producer to ensure production of food of animal origin that is safe for human consumption and acceptable for trade in the world market.

 doi:10.1016/B978-0-12-378612-8.00344-9

GAHP encompass all the measures adopted at the farm level starting from rearing of healthy animals. The general measures that form a part of GAHP in relation to food safety issues are discussed under following sections in the article.

General GAHP

Animal Health

The starting point for implementation of GAHP at the farm level involves maintaining a healthy herd that is free of not only any clinical or apparent disease but also from all subclinical infections. The two most important hazards associated with animal health are the biological agents like bacteria, viruses, parasites, prions, fungus, etc., and chemicals like drug residues, pesticides, heavy metals, environmental pollutants, etc. The animal producers should protect their animals from these agents.

Prevention of Biological Hazards

The primary check to biological hazards should be exercised at the level of entry or exit of any animal from the farm and also monitoring the re-entry of a previously healthy animal. A newly introduced animal should be checked thoroughly for the presence of infection and its vaccination status. The animal should be tested for diseases prevalent in the previously inhabited area and kept separate for the appropriate quarantine period. The entry of personnel should be restricted and no new person from unknown area or endemic area be allowed to enter the farm premises. Entry of vehicles should also be restricted with a separate area of disembarking. Semen, vaccine, and other biological products should be properly screened so as not to introduce an infection to a farm.

Besides adopting measures for preventing the entry of infections, a proper health management program should be instituted so as to maintain animals in good health condition. Animals should be regularly screened for the early detection of disease. Newborn livestock should be administered colostrum to boost their immune system. Proper vaccination and deworming should be done and a record maintained for each animal. Insect population should be kept in check as they may transmit disease to animals and also lead to production loss due to stress. Sick animals should be isolated from the flock, so as to limit the disease at its initial stage. In case of any disease outbreak vaccination should be performed in adjoining farms or surrounding area to prevent spread of disease. In the event of highly infectious diseases like H5N1 avian influenza, mass culling should be done to prevent spread.

Prevention of Chemical Hazards

An emerging problem of major public health concern is the development of antibiotic resistance in pathogens whereby previously treatable diseases of minor importance are fast becoming untreatable. Development of resistance to antimicrobials due to overuse, misuse and underuse during prophylactic and metaphylactic administration to farm animals intended for dairy or meat purpose is well documented today. Use of antibiotics as growth promoters in feed has been cited as one of the reasons for the emergence of resistant pathogens. The resistant zoonotic pathogens may enter the food chain and cause disease in humans. Another food safety issue related to use of antimicrobials and/or veterinary drugs in food animals is veterinary drug residues, which may remain in animal products intended for human consumption and act as a health hazard by causing a variety of health problems in humans. These residues can cause allergic reactions (e.g., penicillin), direct toxic effect like kidney or liver damage, cancer (e.g., inorganic arsenicals), reproductive disorders, etc. Less well known is that antibiotic residues can delay or stop the normal lactic fermentation of products (e.g., salami, pepperoni) resulting in significant economic loss due to poor quality and the risk of excessive growth of antibiotic resistant pathogens.

Realizing the importance of this the World Health Organization (WHO) formulated principles for the containment of antimicrobial resistance in animals intended for food and recommended the reduction in use of critically important antimicrobials, although stopping the use of antimicrobials as growth promoters. The national authorities should monitor the level of antimicrobials and other drug residues in food of animal origin and their comparison with the acceptable standards must be done periodically. Veterinarians must ensure maximizing the efficacy of treatment, whereas minimizing the misuse and overuse of the drugs. Drugs should be administered only after thorough examination and diagnosis by a veterinarian and should only be made available on prescription. The drugs should be administered as per the dose and route prescribed for a particular species. Proper records should be maintained as to the source of the drugs, the animal(s) in which the drug is administered, etc. An important aspect for food safety is to maintain adequate withdrawal or withholding times before harvesting the animal products (e.g., milk) or permitting the slaughter of animals so as to minimize these residues. Records on the administration of drugs should be maintained for every animal or flock.

Pesticide residues and heavy metal residues in animal products are other chemical hazards compromising food safety, which can be controlled by GAHP. Pesticides and heavy metals usually gain entry in the animals through feed and water. Application of pesticides for external parasite control may also lead to presence of pesticides in animal tissue. Animals should not be fed feed that contains high concentration of heavy metals (fodder grown along road sides) or pesticides nor should the farm be close to an industrial area where there is high level of such metals in air, water and soil. The pastures should not be grazed upon immediately after application of any pesticide. The water supply should also be protected from contamination by industrial and agricultural waste.

Feeding and Watering

Feeding is important with regard to the growth and performance of the animals. In addition, it also has impact on human health and food safety. Animal feed can be contaminated with a variety of biological (bacteria, viruses, prions and molds), chemical (dioxin, polychlorinated biphenyl, mycotoxins, pesticides, and drug residues) and physical (metals and glass pieces) hazards. These hazards are excreted as such or

their metabolites may be retained and when slaughtered they may enter the human food chain.

Some recent events highlighting the importance of safe animal feed that shook the economy of their respective countries include BSE crisis in the UK and the dioxin crisis in Belgium. BSE was first observed in cattle in 1984 in a farm in West Sussex and its origin was traced back to feed containing offal (brain) of sheep having scrapie. This lead to disease in 179 000 cattle in the UK alone with precautionary culling of another 4.4 million and a loss amounting to nearly £5 billion. Another crisis occurred in Belgium in 1999 due to contamination of animal feed with dioxin, a carcinogenic compound. The contamination occurred as the fat used for making animal feed was stored in tanks previously used for storing mineral oil. The tainted feed was not only supplied to nearly 1000 farms in Belgium but also to France, Holland, and Germany. This led to a recall of all animal products like eggs, pork, chicken, and beef, and a ban on all Belgian animal products by the EU and the US.

The Codex Alimentarius Commission has developed a code for good animal feeding practices (CAC/RCP 54-2004) to ensure safety of animal feed through adoption of good manufacturing practices throughout the process of procurement, handling, distribution, and storage of feed. The feed should be of good quality and meet the acceptable standards for the presence of pathogens, toxins, and chemical residues to avoid any detrimental effect on animal and subsequently through the food chain on human health. The Codex maximum residue limits and extraneous maximum residue levels set for feed should be applied. Feed stuffs should be protected from any form of contamination and pests. Animal feed that could be a source of BSE (ruminant protein) should be avoided in the diet of ruminants. Chemicals should be kept far away from feed and water and separate equipments/containers should be used to handle feed and chemicals to avoid contamination of the feed with any undesirable residue. Feed additives and antibiotics should be administered judiciously to prevent development of resistance and to avoid presence of residues in the animal products. Water used for making feed should be of acceptable quality. Proper records should be maintained about the source of the feed and all the feed ingredients to maintain traceability. Presence of any undesirable substance in the feed that could compromise food safety should be reported promptly to the concerned authorities.

When animals are reared on pastures adequate assessment should be made about the parasitic load of the area and, if necessary, animals must be given antiparasitic drugs regularly. The pastures should be left for adequate withdrawal period after application of chemicals to prevent any hazard to the animals. Animals should be discouraged from grazing on pastures exposed to contaminated water containing industrial residues or effluents. Normal pasture rotation should also be followed wherever possible.

Water is as important as animal feed in terms of influencing animal health and ultimately the quality and safety of animal food products. Water acts as a vehicle for many hazards of a bacterial (e.g., *Salmonella*, enteropathogenic *Escherichia coli*, *Campylobacter*), viral and parasitic nature that are of concern to the animals and/or to consumers of animal food products. Therefore, care should be taken to avoid contamination of water from sources like animal excreta, human excreta, or any other farm waste. Drinking water used for the animals should be free of pathogens and hazardous chemical residues that might compromise the animal health. The water supply to the farm should be protected from contamination by pesticides and other chemicals applied to the pastures. Water troughs and dispensers should also be cleaned regularly.

Animal Welfare

Animal welfare is linked directly to animal health and involves an animal who is free of any physical, biological, or mental stress. As per the International Dairy Federation (IDF) *Guide to Good Animal Welfare in Dairy Production*, animal welfare involves following five freedoms, which should also be applicable for animals reared for meat production:

- Freedom from hunger, thirst, and malnutrition: The feeding and watering of the animals is very important and has already been discussed earlier. The farmers should follow the code of good feeding practices to ensure optimum nutrition for the herd with emphasis on the physiological state of animal. Young livestock should be fed colostrum at birth and calves should be kept on liquid diet till the full development of rumen.
- Freedom from pain, injury, or disease: The animals should also be kept in good body condition by regular vaccination and timely treatment. A veterinarian should check the animals regularly for sign of any disease. Disbudding, castration, calving, etc. should be conducted under the supervision of a veterinarian and under hygienic conditions. Restraint and milking equipment should avoid causing any injury to the animals.
- Freedom from discomfort: The animals should be housed appropriately as per the need for space, and overcrowding should be avoided at all costs. Housing should be such as to prevent animal from physical injury due to slipping and to allow proper disposal of animal excreta. Animals should be provided with bedding that is clean and of good quality. The physical environment of the animal should be clean and free of any chemical pollutant that might affect them. During transportation animals should be free from discomfort and prescribed standards with adequate space, food, and water should be followed.
- Freedom from fear and distress: General management practices should avoid any fear and distress especially while handling and rounding up the animals. Special precaution should be taken while handling pregnant livestock. They should be handled gently and left for calving or farrowing in a quiet place.
- Freedom to engage in normal physiological pattern and behavior: The animals should be allowed to move freely as per their normal physiological pattern of behavior and should not be exposed to undue stress by interfering in their normal behavior.

An animal allowed freedom as per the above mentioned points will generally be in a state of good health thereby increasing the quality of the animal product. The backbone of

animal welfare is good stockmanship. A good stockman should be able to identify any change in the normal behavior of the animals, any sign of disease or distress. He should be well trained and experienced in the good farming practices.

Building and Housing

Before setting up a farm, importance should also be given to the site, which should be far away from any industry or a previous dumping ground. The aim should be to prevent exposure of the animals to any potentially hazardous substance due to the location of the farm. It is also important that the buildings used for the storing of chemicals should be made at a distance from the animal shed, the milking room and the feed storage building to prevent chemical hazards from entering the food chain. The farm should be properly fenced in order to discourage stray or wild animals and unauthorized people from entering into the farm premises. The farm should be kept clean so as to prevent establishment of breeding ground for rodents and insects.

The shelter and housing facilities are meant for the comfort of the animals and to protect them from the inclement weather. Animal sheds should ensure free movement and total comfort with adequate space for every animal. Overcrowding should be avoided and buildings constructed according to the space requirement of each particular species or stage of animal development and prevalent legislation in that area. The building should allow efficient cleaning, disinfection and disposal of excreta. Floors should be nonslippery and the design and material of the building should not cause any injury to the animals. There should be proper ventilation and drainage to prevent the internal environment from becoming potentially harmful. In tropical countries during warm and humid months the temperature is above 40 °C, so care should be taken while constructing the animal houses to prevent heat stress to the animals. The shed should be kept clean, dry and free of animal excreta and pests. The milking parlor should be kept free of animal excreta at all times. There should be separate farrowing pens or calving sheds to provide calm, quiet and isolated place for the pregnant animals. Similarly a quarantine shed and sick animal shed should also be present in the farm preferably at some distance from the sheds for healthy livestock.

General farm Management and Environment

- Identification of animals: All the animals reared in a farm should be identified primarily for the purpose of ownership and secondarily for the purpose of traceability of an animal or its product. The commonly used methods today include branding (hot/cold), tattooing, tagging using visual code, bar code or transponders, and micro-transponders as implants or bolus. The main purpose of these methods should be to identify the animals from a distance of 1–2 m in large animals and 0.5–1 m in case of small animals. The identification marks should be easy to apply, have good visibility, and cause minimal pain to the animals, although being durable and tamper resistant. They should not contaminate the meat of the animals under any condition. The best method for developing countries where farmers have limited resources is tagging using the visual code. The animals should be tagged at an early age and records be maintained.
- Disposal of waste: The farm waste should be disposed in such a way so as not to cause environmental pollution or act as breeding ground for flies. The animal shed should be regularly cleaned and the excreta removed at the earliest to discourage flies from disturbing the animals. Farm effluents should not be allowed to run into the pastures as they may be a source of pathogens and parasite eggs. If possible the effluents should be treated before disposal on land or water. The dead animals should also be disposed at the earliest at a proper site. The dead animals should either be burned or buried, taking all precautions to prevent digging out of the carcass by dogs. Expired medicines should similarly be disposed efficiently to prevent them from finding a way into the animals' body.
- Cleaning and disinfection of the premises: Following the disposal of waste the disinfection of the farm is important especially in places where an 'all-in' and 'all-out' policy is adopted (e.g., poultry flocks). The animal sheds and houses should be regularly disinfected to prevent outbreak of diseases. Livestock sheds should also be treated with acaricides to control the tick population. The farm equipment like milking machine should be regularly cleaned and disinfected as they may harbor harmful pathogens and may act as continuous source of contamination by the pathogen. In 1999 during Nipah virus outbreak in pig farms in Malaysia, the farm equipment used to carry dead animals acted as a source of infection for other healthy animals. This highlights the importance of regular cleaning and disinfection on the farm premises for safety of food animals.
- Restrict entry to farm: The entry of stray animals and human should be restricted by means of fencing. This also helps in preventing the contact of livestock with wild animals thereby preventing the transmission of diseases from one to another especially those of public health significance. There should be a good pest management plan to control the rodent and insect population at a farm.

Records and Traceability

Traceability is the ability of an animal or an animal product to be linked back to the primary producer. Maintaining of records is an integral part of the good farm practices. Regularly maintained records of every animal or flock from placement on the farm until delivery for slaughter or sale is important in the world market especially to trace back the origin of the animal product in case of any emergencies. This helps in the timely containment of any outbreak due to accurate knowledge about all the hazards encountered by the animals at the farm. Also, the commitment of the farmer to production of safe food animals can be ascertained. Dated records should be kept of every treatment given and drug administered so as to allow proper withdrawal period before utilization of animal products or permitting the animal for slaughter. Records should also be kept of people entering or working at the farm, purchase or sale of any animal, feed procured, pest control adopted and any chemical treatment of shed, pasture, farm premises. In case

of BSE, the tracing back of the feed helped in investigation of outbreak, where the disease was attributed to animal proteins fed to cattle derived from brain of scrapie infected sheep.

Milking Hygiene

Milk is very susceptible to contamination by various pathogenic and spoilage microbes. These harmful organisms may gain entry both when the milk is in the udder and during milking. The following aspects should be considered to ensure milking hygiene at farm level:

- Animal hygiene: The health of the animal is of utmost importance while determining the quality of the milk produced. Animals that are sick especially those having brucellosis, tuberculosis, listeriosis or mastitis should not be used for milking as they may shed the organisms in their milk. Their milk should instead be discarded and they be milked at the last to avoid transfer of pathogenic organisms to the udder of healthy animals. Also important is the keeping clean the coat and udder of the animals as dust and environmental contaminants may enter milk during the milking process.
- Environmental hygiene: A clean milking parlor is equally important in milk hygiene and should be thoroughly cleaned before milking. The milking equipments should also be clean and not cause injury to the animals. In case of manual milking such practices that may injure the udder should be avoided. The milker should use basic hygienic practices and should not be suffering from any infectious disease especially with lesions in the palm region. The utensils used to collect and store the milk should be properly cleaned. Plenty of clean water should be made available on the farm.
- Storage of milk: Raw milk contains some amount of microorganisms, which multiply many-fold under the ambient temperature particularly in tropical countries. It is therefore necessary to cool the raw milk to a temperature below 5 °C immediately after collection. Also the milk storage containers and room should be clean and free of any taint or smell.

Preparation of Animals for Slaughter

Any animal that is intended for slaughter should be in the best of health. All sick or stressed animals should not be sent to the slaughter house till their recovery. Also important in such animals is maintaining the appropriate withdrawal period after treatment so to allow the clearance of drugs from the animal body and making it free of drug residues. A considerable amount of pathogenic bacteria such as *Salmonella*, enteropathogenic *E. coli* and *Camplyobacter* are housed by the animals and birds in their digestive tracts and body surfaces. Under conditions of stress there is increased excretion of these organisms in the feces, thereby increasing the chances of contamination of meat during processing. It is therefore imperative that the animals be free of disease, stress and have a clean body coat. The animals should be fed with the feed, which is high in dry matter content 48 h before slaughter. The feed should be withdrawn 24 h before slaughter, while maintaining an *ad lib* water supply. The animals kept under extensive farming conditions should be brought back to their farms well in advance in order to prevent stress just before slaughter. The animals should also carry proper identification mark before leaving the farm.

Future Changes in GAHP through the Use of Risk Analysis and Risk Management

A great deal of research is being conducted in developed countries to control specific pathogens at the farm level. The data are analyzed to identify and determine the relative value of various control measures. Risk management strategies are then identified and implemented at the national or regional level for pathogen control. Some of the notable examples worth mentioning include the control of *Salmonella* in poultry and pigs in Denmark. The main highlights of control in poultry were extensive testing of the flock and destruction of infected breeder stock, thorough cleaning and disinfection of the poultry house with a rest period of 10–14 days between flocks, although abstaining from use of culture exclusion, antibiotics and vaccines.

Similarly, in the Danish pig population, preharvest control with new feeding strategies (coarseness of feed and wet feeding), improved management with an all-in and all-out strategy, continuous monitoring of the herd and hygienic practices have greatly reduced *Salmonella*.

The proportion of layer flocks infected with *Salmonella*, especially *Salmonella* Enteritidis, was reduced from $>7\%$ in 1998 to $<2\%$ in 2001 through this program. Since then, significant progress has been made throughout much of the EU with the use of an effective vaccine.

In the case of *Escherichia coli* O157:H7 in beef cattle, various practices, like use of probiotics and bacteriophage vaccines – that have been approved by the US Food and Drug Administration (FDA) – have contributed to the decrease of shedding, whereas management practices, such as clean bedding, pest control, and sanitation have reduced the spread, but not the fecal excretion of the organism. Despite improvements in preventive measures such as GAHP and the application of combined good hygienic practice and hazard analysis and critical control points (HACCP) during slaughter, testing of trimmings and ground beef continues to be used in certain countries as an additional measure to prevent ground meat contaminated with *E. coli* O157:H7 reaching the market.

Control of listeriosis in France is another example of modifying traditional GAHP for on farm control and reduce the presence of *L. monocytogenes* in soft cheese made from raw milk. Collectively, these examples demonstrate that specific microbial pathogens of concern to humans can be minimized by making specific adjustments to the traditional application of GAHP. The continuing research efforts will definitely lead to future case specific/target specific modifications in the GAHPs as mentioned in this article.

Conclusion

With the increase in global trade and advent of the Agreement on Technical Barriers to Trade (TBT) and Agreement on the Application of Sanitary and Phytosanitary (SPS) Measures

food safety has become an important issue and various world organizations such as FAO, OIE, WHO, Codex, International Commission on Microbiological Specification for Food (ICMSF) and IDF are coming up with various guidelines and standards for food safety management. The above-mentioned GAHPs are a set of simple everyday practices that can be implemented at farm level by the primary producer to ensure that the animal products that he produces are safe for human consumption. In the case of developing countries where animal rearing is not a well organized enterprise and where animal farmers usually have limited resources, co-operatives or private meat companies can help farmers to raise livestock and poultry to produce animal food products though practices such as contract farming and backward integration. Under these schemes quality stock, feed and veterinary services are made available by the companies, thus ensuring quality animal products.

FOOD SAFETY ASSURANCE SYSTEMS

Building Design

HLM Lelieveld, European Hygienic Engineering and Design Group, Bilthoven, the Netherlands

Glossary

HEPA filter High-efficiency particulate air filter, an air filter that removes at least 99.97% of all particles larger than 0.3 μm from the air that passes through the filter.

Listeriosis A disease caused by ingestion of food contaminated with the bacterium *Listeria monocytogenes*, which can be harmful and sometimes fatal for babies, elderly, and immunocompromised people.

Mycotoxins Substances produced by species of molds that can be toxic for humans at a very low concentrations, μg/kg (micrograms per kg).

Rodent resistant Designed to withstand ingress of rodents (relates to food factories in particular).

Introduction

The integrity of a building influences the access of pests (rodents and other small crawling animals, birds, and insects), microorganisms, dust, and polluted air to the products that are produced. The chances of such contamination depends on the environment of the factory and, therefore, it is important to pay attention to the site. The higher the concentration of any type of contamination in the environment, the more difficult it will be to ensure that the production area will be suitable for the production of safe food products and consequently, the more expensive it will be to meet the food safety requirements.

Reconstruction and maintenance works often are done while production is continued in other areas of the same building. At such times, the safety of the food processing operation may be severely challenged. Adequate measures to prevent loss of integrity of the operation must be taken before such works start or otherwise, the food operations must be interrupted until these works are finished and inspection shows that the plant is clean and ready for resuming production.

Regulatory Requirements

To protect the consumer, many countries currently have strict requirements with respect to food safety. However, the enforcements may be insufficient because in many countries legislation is weak or there is insufficient inspection capacity to ensure that regulatory requirements are met. Traditionally, this has to do with governmental budgets and priorities. After well-publicized food scares, the budget will temporarily be higher. Although the food safety requirements may be fairly, but certainly not completely, similar among countries, it may be obvious that there are differences in requirements with respect to the environment and buildings. This is because the burden of hazards varies between regions. Factors, such as local climate (particularly temperature and humidity), domestic pests, husbandry (use of manure), degree of air and soil pollution, and geological conditions may lead to differences in the concentration of undesirable chemicals and microorganisms in the environment of the factory. Some countries are prone to earthquakes, others to flooding, and some to both. Consequently, risks of food safety incidents may also differ. Although in many countries food safety regulations are in place, the situation is rather different for environmental regulations. In some countries, such regulations are nonexistent. The consequence is that the environment of a factory may unexpectedly change and cause tremendous problems. Authorities may decide that a certain location is the best one to dump municipal wastes because if it is nearer the residential area, it will affect the opinion of the electorate. Nevertheless, in many countries, the law requires that the premises (buildings) for food handling and processing are hygienic. These laws, however, do not specify how this must be done and hold the company fully responsible for ensuring that the premises are hygienic. An organization that does provide guidance on meeting the hygiene requirement is the European Hygienic Engineering and Design Group (EHEDG), see www.ehedg.org.

Retailer's Requirements

Retailers are the first line in dealing with the complaints of consumers; they need to care about their reputation, in particular when they have their own labels. Therefore, retailers have good reasons to have their own requirements with respect to the hygienic condition of the factories from where they obtain their products. Even in countries where food safety regulations are adequate, retailers increasingly inspect and certify their suppliers for the simple reasons that the regulators usually either fail to do so or are not effective.

 doi:10.1016/B978-0-12-378612-8.00352-8

Site Selection

The site influences the design of the building in order to cope with the local conditions that may influence food safety. Examples are the quality of water and air, and the presence of local pests (insects, birds, farms, water treatment plants, etc.).

If the site is in an area with a more than an average concentration of airborne microorganisms, insects, and birds, there is also an above average chance of contamination of unprotected raw materials (such as often the case with fresh produce and meat) during off-loading. Sites near waste treatment plants and farms, in particular if downwind from them, may have to cope with severe problems because untreated wastewater and manure are likely to contain high concentrations of pathogenic bacteria, including *Vibrio*, *Salmonella*, *Escherichia coli*, *Campylobacter*, and *Yersinia* sp., and *Shigella* in addition to protozoa and viruses. These microbes may become airborne depending on the design of the wastewater treatment system and at times when farmers spread manure over the land to fertilize it. They will challenge the factory's air system. In addition, every time an entrance is open, anything flying may successfully attempt to get into the factory. The building must then be provided with loading and off-loading bays that reduce this risk to an acceptable minimum. For the same reasons, any entrance for people, materials, and air will need additional measures to keep the contamination risks low enough. This is an important aspect in the selection of a suitable site. It is better not to have the factory near a sewage treatment plant but also to make certain that such a plant will not be situated near the factory in the future. The same applies to legal waste disposal facilities and landfills. This requires checking the local zoning plans and obtaining, in writing, that within a certain distance from the factory, such plants will not be built. Nearby chemical industries may produce potentially toxic substances, which may contaminate not only the air but also the soil (with e.g., heavy metals or chlorinated hydrocarbons), which is particularly important if well water is used, as discussed below. One should be aware if the site under consideration has been polluted, for example, as a result of mining activities, chemical industries, or (legal or illegal) waste disposal. The presence of pollution in the soil should best be carefully checked.

Another requirement is the quality of water that is and will be available at the site. There are large areas in the world where safe water is readily available, but there are also large areas where it is not, not constantly or not of a constant quality. If available, but of unacceptable quality, an in-house water treatment facility must be installed and maintained. If the availability of water cannot be guaranteed, a well may have to be drilled. Such measures will add to the costs of the final product.

To operate a factory, energy is required. The energy supply may be unreliable, in particular with respect to electricity. This may severely undermine food safety management and cause conditions prone to incidents because electricity is essential to maintain conditions that prevent the ingress of contaminated air, such as maintaining pressure differences among the various zones in the factory. The same holds for cooling and freezing and for the operation of measuring, controlling, and registration equipment. If the electricity fails, so will the control of processing temperatures and flow rates through pipelines. Hence, if interruptions are likely to take place, adequate back-up systems (e.g., oil-powered electricity generators) must be installed, the capacity depending on how long the interruptions may last. It is important to obtain a guarantee from the local electricity supplier and to be certain also to ask advice from a reliable local consultant.

Site Layout

For the same reasons as discussed Section 'Site Selection', the layout of the site must prevent access of pests into the factory. To keep the animals at bay, there must be fences that are high enough to prevent dogs and cats from entering the area, but at the same time be deep enough to prevent burrowing animals (rats and rabbits) to gain access. The fences must be such that they do not allow animals (including monkeys) to climb over it. Any unpaved surface must be covered with grass that is kept short to avoid breeding of small animals. For similar reasons, there should be no shrubs or trees or they should be far away from the factory wall and particularly its entrances and air inlets. Because they provide places for microbes and insects to breed, there should be no ponds or any other possibilities for stagnant water or mud. For these reasons, pavement should be horizontal or slightly sloping toward drain pits.

External lighting should always be away from the factory walls and entries, luring the insects away from the building instead of attracting them to it.

It is all about preventing insects, small animals, and microbes from multiplying and worsening the environment of the factory: Waste disposal areas too must be such that they do not allow ingress of insects and animals. Moreover, to limit undue growth of molds and bacteria, dry solid waste should be kept dry. It means that, although the disposal area must be outside the factory, it should nevertheless be covered to cope with precipitation. Doors to the area must be rodent resistant and be tight against insects. The doors should preferably be self-closing, otherwise an alarm should go off when the door has been open for a longer time (minutes, rather than hours).

Access to Production Areas

The entrance of the production area must be equipped with hand-washing facilities, such that everybody entering the area must pass these facilities. Restrooms (toilets, washrooms, lavatories) must not be directly connected to the production area and must be easy to clean. Depending on the type of products handled in a certain area, it may be necessary to minimize the risk of transfer of contamination from the outside into that area by using a change room, where garments can be exchanged for special production room garments. It should have a step-over barrier to leave shoes and boots that are worn outside, on one side, and on the other side to put on footwear, to be used exclusively in the production area. The step-over must be sealed to the floor to prevent contamination on the floor from moving to the production area. There must be means for cleaning, disinfecting, and drying of hands.

Processing and packaging areas should not be used as a passage to canteens or other amenities. Therefore, the layout of the building should take into account that the cafeteria, kitchens, offices, laboratories, workshops, chemical stores, etc. are not connected to the production and packaging areas. Anybody, including laboratory staff, directors, and important visitors, if they need to be in the production area, should pass the change room or hand-washing facilities, as applicable, and use them as per the personal hygiene instructions. Similarly, any vehicle that is needed to transport raw materials, ingredients, or finished products should have designated routes that should not be used for anything else.

Building Design

Supporting Structure, Foundation, External Walls, and Roofs

The supporting structure of the factory should ensure that the floor is at an elevated level, so that in case of rain or other precipitation, there is no risk of water or mud entering the factory. Preferably, in areas with potentially heavy rainfall, the level of the supporting structure should be higher than any area in the surrounding to avoid the factory being flooded with the heavy rainfall.

Apart from their function to protect the factory from bad weather conditions and sometimes sun, the external walls, roofs, and the foundation are the first and most important barriers to ingress of pests, in particular rodents, geckos, birds, and insects. Hence, the design must be such that there are no openings that allow animals and insects to enter the building. In addition, it must be ensured that the structure is such that rodents, and termites in some areas in the world, cannot create access into the factory. Any area between the ceiling and the roof must be entirely closed off to prevent these areas from being used for nesting by birds, mice, or rats. Bird droppings contain high concentrations of microorganisms, including pathogens such as *Salmonella*. Special attention should be paid to effectively seal the connections between the roof and walls. Similarly, the connection between the foundation and the wall must be rodent proof.

To avoid attraction of vermin to the roof, the roof should be kept dry and, therefore, slope. External walls and roofs should be easy to clean and maintain. The outer walls should not have ridges or other protrusions that allow birds to settle and breed. Where they are unavoidable, adequate measures should be introduced to discourage birds from settling.

Entry and Exit Points

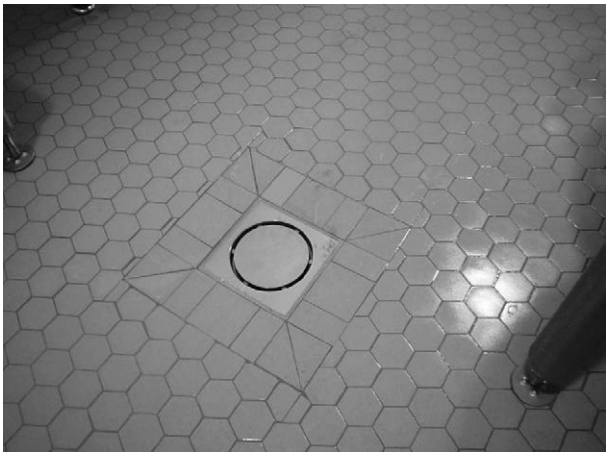
Entry points should be designed such that they allow passage of personnel and goods but prevent the entry of pests as effectively as possible. This requires automatically closing doors that are rodent resistant and in some locations also termite resistant. The doors should close such that even small insects, such as ants, cannot gain access.

It is important to build the factory in such a way that the openings are downwind, at least as much as possible, so that wind is not blowing any undesirable matter into the factory. Doors and windows that normally are not used are places where insects may breed in the narrow space between the frame and the door/window. Hence, care must be taken that such crevices are very small or, if indeed only to be used in emergencies, be sealed with a good quality of tape that is resistant to cleaning chemicals and conditions, but do not hinder opening of that exit in case of emergencies.

For security reasons, visitors should always report to the main entrance and not gain unauthorized access at any other entrance. Therefore, just after the main entrance, there should be an area where visitors can be met and kept under control until cleared and collected by a company staff member.

Internal Walls, Floors, and Ceilings

Walls must be nonabsorbent and well cleanable, and therefore not have recesses or cracks that can harbor insects. Where the wall can be hit, it must be able to withstand damage that may result in product contamination. For the same reason, any paint used should be of a quality that does not flake off. The use of strong, slightly elastic wall coatings is recommended. Corners may have to be protected by metal reinforcements. The same applies to the lower part of the walls, where bumper constructions should prevent damage when fork trucks may incidentally hit the wall.



The floor often plays an important role in product contamination incidents. Improperly designed floors may accumulate moisture and nutrients for insects and bacteria. Moving (of e.g., people or vehicles) over such floors produces aerosols that carry microorganisms. Insects full of microbes may crawl out and enter the product, visibly or not. Hence, floors unless in areas that will never be wet must be watertight and slope toward drains, so that any spilt liquid can be easily removed. The floor must also withstand cleaning chemicals and the temperature of hot water that may be needed for cleaning. Floors must be able to withstand damage by moving around of personnel and by moving of equipment. Since the 1970s, composite floor materials (epoxy, meta-acrylate, polyester, and polyurethane) have become popular, in particular, in new or refurbished factories, but often with disappointing results. The materials are not as strong mechanically, as good quality tiles. Forklift trucks, containers with raw materials or

intermediate products and waste containers, can easily damage such floors. The floors must also withstand the installation of machinery. If machines are installed on an intact epoxy floor, the integrity of that floor may be affected and moisture may penetrate to the supporting structure. The microorganisms and insects developing under these floors cannot be removed without removing the affected area of the floor. If the floor is to be subjected to heavy loads and to the movement of forklift trucks or similar equipment, tiles are to be recommended. Care must be taken, however, that the tiles are grouted such that no moisture is absorbed, creating undesirable circumstances. Hence, the grouting must be resilient and water repellent. It is also easier to repair a damaged tiled floor than a damaged composite floor. Although floors should be easy to clean and hence be smooth, they should not be so smooth that they will be too slippery to walk on. Despite the drawbacks, there may be applications where composite floors provide the best solution, taking into account the prevailing operation conditions.

To allow effective cleaning, the transition between floor and walls must be rounded. For tiled floors, special tiles are available.

To avoid dust falling down on the exposed product or product contact surfaces, ceilings must be tight and, hence, false ceilings should not be used in food processing plants. Suspended service ceilings, however, are fully acceptable and provide the advantage of mounting cables, service ducts, etc. above the process area from where they can be extended downward, vertically, to where they are needed. This way, the risk of contamination of the product by dust that accumulates on these provisions is drastically reduced. The construction of these service floors must self-evidently be such that it does not allow any dust to pass from the area above the ceiling to the production area, which means that the passages of the ducts, etc., must be effectively sealed.

Lighting

There must be enough light in the factory firstly for the personnel to do their job properly and efficiently and secondly to be able to notice dust, dirt, and detect vermin or their traces. To avoid the risk of contamination of the product with glass, generally glass windows are avoided, but modern types of glass are very strong and are available in shatterproof quality. If well mounted, they will not easily break and if they do, they do not splinter into small pieces, even if accidentally struck with a fairly great force.

Lamps for artificial illumination must be covered by shatterproof covers that are tight, so that an exploding lamp cannot contaminate the product. To avoid accumulation of insects and dust, lighting should preferably be mounted in the suspended service ceiling, with the underside flush with that ceiling. Besides preventing the collection of dust and insects, it also enables the replacement of the lamps from the top, without interruption of the production. In the absence of a suspended ceiling or if that ceiling is too high above the surfaces to be illuminated, the top of the housing of the lamps must slope down at an angle of approximately 45° ($\pi/4$), to prevent anything from settling.

Temperature Control

For the comfort of the personnel in the factory, it will often be needed to condition the air, at least to some extent. Where food must be processed under chilled conditions, cooling units are used. These units have trays underneath to prevent condensate from dripping onto people and the product. What is not realized but is very important from a food safety point of view is that these trays are perfect places for the selective cultivation of psychotropic bacteria, specifically *Listeria monocytogenes*, a pathogen that may cause listeriosis. It is a fairly selective process because at low temperatures, *L. monocytogenes* grows faster than most other microorganisms. The fans of the cooling unit complete the food safety risk because the circulation of air helps to spread the contaminated condensate over the product. Therefore, collectors of condensate should always slope to one side, from where it is led to a hygienic drain pit. Moreover, they need to be easily accessible for regular inspection, cleaning, and disinfection.

To make the control of the temperature efficient and affordable, as well as to prevent condensation on walls, ceilings, and windows, thermal insulation of walls and roof (and/or service ceiling), and double-glass windows are needed. Care must be taken that the installation of insulation panels does not create a space for the breeding of insects between the wall and the panel. The panels should be smooth for ease of cleaning and their surface should be strong enough to prevent damage under the applicable conditions.

Noise Control

Machinery may produce more noise than is desirable or legally acceptable. Noise absorbing panels may be used and have been used on a large scale. Nevertheless, because they must be cleanable and hence their surface must be smooth, the hygienically acceptable panels are not very effective. Increasingly, food processing machinery is designed to produce significantly less noise than a few decades ago. If however the noise levels are still high (which still is not unusual), the best solution may be encasing the noisy parts using panels with the sound absorbing surface on the inside and having a smooth outer surface. There may also be situations where it is more attractive and efficient to use noise-canceling earphones for personnel working near noisy machinery.

Sewers, Gutters, and Drains

The sewer can be a serious way of contamination of the interior of the building. The design may be such that even large animals, such as rats, gain access, unless appropriate measures are taken to prevent this. The design must also be such that there cannot be pressure differences large enough to cause gases to enter the interior of the factory in any way. It is highly recommendable to keep the sewer system physically separated from other wastewater systems, which are connected to floor drains throughout the factory. Gutters tend to be covered by perforated covers and cleaning the gutters and covers is usually troublesome. Moreover, water, often contaminated with spilled products, tends to be stagnant in most parts of the gutters, allowing microbial growth and nesting of cockroaches and other insects. Gutters

therefore should be avoided and hygienic floor drains should be used instead, while the floors should slope toward these drains. The drains, however, can also become breeding places for insects and bacteria. Therefore, they should be of a design that can be disinfected. In high-care areas they should preferably be of a kind that can hold disinfecting substances.

Internal Zoning, Ventilation, and Air Conditioning

An adequate air supply is needed to ensure a sufficient supply of oxygen and to control the temperature in the production environment. Depending on the temperature required and the amount of heat produced by the machinery or the processing of the product, the amount of air needed may vary greatly between factories and hence also the dimensions and design of air ducts and exhausts. To make the risk of airborne contamination of exposed product or food contact surfaces as low as possible, the air should flow from the exposed final product area, through areas where such contamination is less important, to the area where materials arrive. That requirement influences the differences in pressure needed between the various zones in the building. The air supplied to the cleanest areas should self-evidently be adequately filtered, to the degree needed to meet the product safety requirements. High-efficiency particulate air (HEPA) filters will be required where microbiologically vulnerable products are exposed to the air. Between prefilters, intended to remove course particles and insects, and the fine (HEPA) filters, intended to remove microorganisms, dehumidifiers must be installed to ensure that the fine filters remain dry and to prevent condensation in the production area. The combination of differences in temperature and humidity may result in condensation and hence wet spots in the process area, resulting in the growth of bacteria and molds, which may become airborne and contaminate the product. Hence, care must be taken that either such condensation cannot take place or takes place under control, at easily accessible locations, enabling inspection, cleaning, and disinfection. Air inlets should be positioned at a distance from the air outlets of the factory to prevent contaminated air to unnecessarily burden the air inlet filters and dehumidifiers. Both inlets and outlets must be provided with screens to prevent entry of flying animals and insects.

If at the factory materials that contain allergens are processed, special attention should be paid to airflows to avoid that air from the area where allergenic products are processed can pass to areas where products are processed or packed that must be or are supposed to be free from these allergens.

Zoning of food production premises is important to prevent (re)contamination of exposed food and also proportionate use of protective measures and verifications (e.g., environmental monitoring). Details on zoning can be found in Todd *et al.* (2010). It may be difficult to realize appropriate zoning in very small premises. Nevertheless, if vulnerable products are made in such premises, the zoning rules should be met or such products should not be produced.

Walkways and Stairways

Footwear, including the special footwear that has been put on before entering the production hall of the factory, collects dust and dirt and hence may shed off dirt again when the wearer moves around. It would be safest if the feet of any person who needs to be in the factory during production would stay below the level of any exposed food product and any food contact surface. There are circumstances, however, that necessitates staff to cross over such areas and hence stairways and bridges are needed. It may be required that during production, parts of machinery that are positioned high on a tall machine, must be adjusted or replaced. In such a case, an elevated walkway is needed. Stairs, bridges, and walkways must be designed and constructed such that no dirt from footwear can contaminate the food and food contact surfaces. Consequently, open structures are not acceptable and there must be sides that are high enough to prevent any dust or dirt from falling down.

Process Support and Utility Systems

To operate the food processing and packaging equipment, products, ingredients, cooling or heating media (steam, water), air, electricity, signal cables, packing material, all have to be brought to where they are needed. This requires pipes, cables, conveyor systems, and support structures. Together this can become a nightmare from a hygiene point of view. If put together, which is unavoidable, because they all need to reach the same machine, they form ideal places for insects and other pests to hide and breed. They collect dust and dirt and are a source of dead insects that may fall down to contaminate product underneath. Moreover, this will be very difficult if not impossible to clean.

Cables (electric power supply and signal transfer) and small pipes (compressed air, nitrogen, and lubricants) should best be grouped together in ducts, which can be larger pipes or of special designs. To prevent ingress of insects, these ducts must be effectively sealed at any entry or exit point of a cable or pipe, at least at the processing side. When building a new factory, probably the best way would be to have a service area below the production floor, provided that the space will be high enough for the access of service personnel. From that area, service ducts may go up to the machine and the cables and pipes stay largely below the exposed product level. If a service floor is not possible, a suspended service ceiling can be a good solution. The passage of the ducts through the floor or ceiling must be such that nothing else, even air, can pass through.

Pipes for transport of product or product ingredients may have to pass through walls or ceilings between various processing departments. Care must be taken that such passages are either tight, not allowing anything passing around them, or large enough to allow cleaning and inspection of the passage. If tight, the construction must be such that they remain tight with time and hence the passage can absorb vibrations caused by machinery to which the pipes are connected and the changes in length and diameter of the pipes as a result of thermal expansion.

Where product or packaging material must pass through walls or ceilings using conveyors belts, chains, or slides, care must be taken that the passage itself is cleanable and accessible for cleaning and inspection.

Food Storage Rooms

Food storage must be designed to make certain that insects and other pests cannot reach the food, even if the food is packed. It must be possible to control the humidity to ensure that the area is always dry. Temperature control and monitoring is essential for storage of perishable products. Entrance of insects and small animals can be prevented by building the storage room on an elevated level, but such that the entrance is also higher than the outside pavement. Furthermore, the storage room should meet the general requirements that also hold for the processing area to ensure that the space can be cleaned: smooth walls and ceilings, no ridges, no surface cracks, and other crevices where insects may hide. Walls must be watertight to avoid wet surfaces at the inside. It is important that the lighting is sufficient for inspection to notice any traces of vermin. There must be enough space between the wall and the stored products for inspection.

Storage of Grain

Large qualities of grains (rice, wheat, corn, etc.) usually are stored in silos. Self-evidently, the silos must be sealed to avoid the entrance of vermin. Chances are, however, that there are insects already in the grain. Measures should be effective in ensuring that there will not be any larger animals in the silos. The insects should be prevented from multiplying by keeping the product dry. Insects, like other animals and people, need water to survive and the absence of water may perhaps not kill all insects, but at least the survivors would be dormant. Another, equally important reason to make certain that the grain remains dry is to prevent molds from growing. Molds may produce metabolites that are toxic (mycotoxins) for humans in very low concentrations. For instance, *Aspergillus* species produce a variety of aflatoxins. The European Union regulations require that the concentration in grains for human consumption of all aflatoxins together is below 4 $\mu g\,kg^{-1}$. Ochratoxins are produced by some *Aspergillus* as well as *Penicillium* species. The maximum concentration in grain for human consumption of Ochratoxin A, the most important one, is 3 $\mu g\,kg^{-1}$ (these are parts per billion, $1{:}10^9$!). Mycotoxins are also harmful to animals (e.g., horses) and hence the above also applies to feed.

The problem with large silos is that it is difficult to ensure that the temperature is the same everywhere in the product. Temperature differences, however, will cause transport of moisture to the colder spots, which subsequently may become moldy and thereby toxic. It is therefore recommended to use thermally insulated silos.

Storage of Oils

The solubility of water in oil is strongly temperature dependent. At 20 °C, the solubility in sunflower oil is approximately 75 mg kg^{-1}, and at 40° C it is approximately 50% higher. The consequence is that in oil that contains more water than is soluble at the lowest temperature in the storage tanks, water will come free. In addition, if the tank is not well insulated, water may condense at the inner wall of the tank. Because of its higher density, all water will sink to the bottom of the tank and where there is water and nutrients, microbes will grow and this way the oil becomes contaminated with microorganisms that in turn may produce potentially toxic substances. The message is that it is important to control the temperature of the room for storage of oils and to prevent oil from cooling down. In other words, letting the temperature drop in wintertime to save energy is not a good idea from a microbiological safety point of view.

Storage of Chilled Food

Self-evidently, chilled food storage rooms need adequate temperature control. It is important to take into account that lighting and ventilators produce heat and that as a consequence, despite the temperature control, there are temperature differences in the cold room. Similar to the chilled rooms for food processing, condensate trays underneath cooling units should slope toward a drain, from where it is led to a hygienic drain pit. The trays need regular inspection, cleaning, and disinfection.

Storage of Packing Material

Some packing materials, in particular carton and paper and the increasingly popular biodegradable materials, are substrates for microorganisms and should therefore be kept dry to prevent microbial growth. Other materials, such as glass, metals, and nonbiodegradable polymers, can be stored in areas without temperature and humidity control, unless the humidity at the location is extreme. Switching from nonbiodegradable to biodegradable materials will probably need measures to prevent microbiological problems.

Storage of Chemicals and Lubricants

The design and location of the store, housing chemicals for cleaning and sanitation, must be such that any risk of contamination of the product and packing material with chemicals is avoided. The store must be provided with a lock and there should be no direct connection between product areas and the chemicals store. The same holds in principle for lubricants, glue, and inks needed in the process and packaging areas, unless the lubricants, glues, and ink comply with the requirements for food contact material or they are used only in areas where there the product is packed in well-sealed containers.

Storage of Refuse and Waste Materials

There must be adequate space for storage of accumulating waste materials, such as used cartons and boxes, enabling 'good housekeeping' in the entire factory. Without such spaces, pests (including rodents and cockroaches) will find places to harbor and breed.

Hygienic Design of Equipment

AN Murray, Hermanus, South Africa

Glossary

Nonproduct contact surface All exposed machinery surfaces other than the product contact surfaces including, where applicable, the splash area.

Product contact surface Machinery surfaces that are exposed to the product and from which the product or other materials can drain, drip, diffuse, or be drawn (self-returned) into the product container.

Splash area Areas composed of surfaces where product may come into contact and not return to the product container.

Introduction

The hygienic design of food processing areas is necessary in order to ensure the safe removal of microorganisms and contaminants during routine sanitation. The hygienic design of equipment is most important because all processed foods make contact with equipment during their manufacture. Poor design can also lead to increased cost, both indirectly and directly as a result of possible food safety failure. The risk of contamination increases where good hygienic design principles are not applied. In addition, poor design results in additional cleaning and sanitation inputs, and thus contributes to environmental risk and unsustainability.

Hygienic design must take account of both the materials of construction and physical design of the product contact surfaces, nonproduct contact surfaces, and splash areas. Those surfaces that do not come into contact with the product have different design requirements compared with those that do make contact.

Strategy for Design

A hazard analysis should be undertaken as a part of the design of food process equipment. This hazard analysis needs to consider the following:

The intended use of the machine,
The product type,
Further processing that will take place,
The application of the product (particularly making a note of the expected consumers of the product),
The cleaning program that will be applied, and
The maintenance program that will be applied.

Once risks have been identified, the design should take these into account and if there are any risks that cannot be eliminated through design these should be addressed by way of cleaning or operating instructions or by limiting the use of the machine. Risks to safety of personnel and environmental risks will need to be assessed simultaneously with hygienic risks and may influence the hygienic design.

Materials of Construction for Product Contact Surfaces

Materials of construction for product contact surfaces may be divided into four types: metals, elastomers, plastics, and other nonmetallic substances.

Metals

Stainless steel is in most cases the preferred construction material for product contact surfaces in the food industry.

Aluminum is not recommended as a product contact material. It also has limitations as a structural material because it is not resistant to some cleaning chemicals.

Copper is generally not suitable for product contact surfaces but is traditionally used in certain industries, particularly distilling and jam making.

Titanium is a possible alternative to stainless steel in cases where the risk of corrosion is severe. This is generally limited to heat transfer surfaces such as heat exchanger plates where welding is not required.

Stainless Steel

Stainless steels are a family of chromium (Cr) containing alloys with a minimum Cr content of 11–12%. The properties of different steels vary considerably as a result of their composition and their treatment during manufacture. Corrosion resistance and cleanability are not the only criteria for the selection of a stainless steel grade. Steel is available in different forms such as plate, bar, or tube and the availability of the required form may also influence the design.

The alloys used in the food industry are generally divided according to their composition onto the following types: martensitic, ferritic, super ferritic, austenitic, super austenitic, and duplex stainless steels.

There are several identification systems for stainless steel. The American Iron and Steel Institute (AISI) grades are also

Table 1 Composition of some stainless steels

AISI	*DIN*	*Typical analysis*				
		%Cr	*%Ni*	*%Mo*	*%N*	*%C*

used. The composition of the more usual grades used in the food industry are given in Table 1.

Martensitic Stainless Steels

Martensitic stainless steels contain 12–18% Cr and a high carbon content. They have moderate corrosion resistance and poor weldability but are hardenable by heat treatment. For this reason, they find a use in knife blades and springs.

Ferritic Stainless Steels and Super ferritic Stainless Steels

Ferritic stainless steels are high in Cr and low in carbon. They have a moderate to good corrosion resistance and good strength. They cannot be hardened. Their weldability is moderate to poor. The main use for these steels is in domestic hardware, sinks, cutlery, and table tops. Ferritic alloys are used for steel structures, walkways, and stairs.

Super ferritic steels have added molybdenum (Mo) (typically 1–2%). This gives an improvement in the resistance to pitting and stress corrosion cracking (SCC). However, because of their poor weldability, they do not readily replace the austenitic steels for fabricated items.

Austenitic Stainless Steels

Austenitic stainless steels include the 304, 304L, 316, and 316L grades that are commonly used in the food processing industry.

Type 304 has a composition of 18–20% Cr, 8–12% nickel, 0.08% maximum carbon, 2% maximum manganese, and 1% maximum silicon. Grade 316 has a similar composition except that the Cr is reduced to 16–18%, and 2–3% Mo is added. The low carbon grades of each (304L and 316L) have a carbon content reduced to a maximum of 0.03% to avoid sensitization during welding.

Testing for the presence of Mo is a common way of distinguishing between the 304 and 316 grades.

Properties of these steels are as follows:

Excellent corrosion resistance (improved by Mo content),
Excellent weldability particularly the L (low carbon) grades,
Good formability and fabrication properties,
Good strength and hardness, and
Good cryogenic ability.

Their main limitation in the food industry is that these grades are susceptible to halide, particularly chloride ion attack resulting in pitting and SCC.

Duplex Stainless Steels

Typical of this type is the proprietary steel SAF2205. These steels have a high Cr content as well as nickel and in most cases Mo. They do not fall entirely into any of the other categories. They are weldable, have a very good strength and are particularly resistant to pitting and SCC in the presence of chloride ions.

They find application in desalination plants and also in food processing applications where chlorides are present in the presence of acids (e.g., sauces).

Corrosion and Corrosion Resistance of Stainless Steels

Stainless steel is not immune to corrosion but is resistant to many forms of corrosion.

The resistance of stainless steel to corrosion is due to the formation of an extremely thin but uniform continuous film of Cr-rich oxide on the surface of the metal. This film needs to be repaired after any mechanical damage to the surface. Normally, the film will form spontaneously in air but critical areas or components may, after manufacture, be passivated with nitric acid under controlled conditions.

Some of the forms of corrosion on stainless steel are general corrosion, galvanic corrosion, erosion and abrasion, intergranular corrosion, pitting, crevice-shielded corrosion, microbiologically induced corrosion, and SCC. Of these,

intergranular, shielded corrosion, pitting, and SCC are the most important in food industry situations.

Intergranular Corrosion

The formation of complex carbides at welding temperatures (450–850 °C) occurs. The use of the low carbon (L) grades of stainless steel for fabricated items is one of the ways of preventing intergranular corrosion. There are tests available for the susceptibility of steels to this form of corrosion.

Pitting

Pitting refers in particular to chloride attack. Under suitable conditions, the chloride ion possesses the ability to attack any localized weak points in the passive film, resulting in the formation of microanodes in a large surrounding cathodic area. The chlorides are attracted to the pit and hydrochloric acid formed in the pit base accelerates the corrosion.

Crevice (Shielded) Corrosion

This is the corrosion that occurs through concentrations of corrosive material collecting under washers, bolt heads, and other similar places. Crevice corrosion can occur both in splash areas and on product contact surfaces.

Stress Corrosion Cracking

The start of SCC is similar to pitting. If the pit is formed under conditions of tensile stress and particularly at higher temperatures, a crack may be formed leading to a mechanical rupture. The mechanisms are complex. SCC is in practice limited to austenitic crystal structure. SCC will not occur under conditions of compression.

Fabrication and Welding of Stainless Steel

To avoid their contamination by carbon steels, the fabrication of stainless steel components should be carried out in an area separate from any similar work on carbon steels. Wire brushes should therefore be made from stainless, not carbon, steel. Layout or cutting tables that are made from carbon steel should be covered with cardboard or plastic sheets to prevent contact between the two materials. Carbon steel slings and hooks, and the forks of lift-trucks, should have wooden or plastic guards.

During the welding process itself, the molten metal must be shielded from atmospheric oxidation by means of a gas, slag, or vacuum in order to achieve and preserve the optimum corrosion resistance and mechanical properties in the joint.

On either side of a weld-run, the parent metal will have been heated to a temperature approaching its melting point and these areas are known as heat affected zones (HAZ). How the characteristics of the weld-metal and the HAZ will be affected will depend on the composition of the stainless steel and the weld technique, including the use of filler metals, and on subsequent chemical treatments.

All welding of all grades must be followed by an effective postweld cleanup. The heat of welding will leave areas of oxidation (known as heat tint) near to the weld, which will have a significantly reduced resistance to corrosion, and this must be restored by removing the tint, ideally entirely. Pickling is the controlled corrosion of the surface and will remove this undesirable oxidation. The usual medium is 10% nitric/3% hydrofluoric acid in a bath at approximately 50 °C. Local areas may be treated with the use of pickling pastes.

Although not strictly necessary after pickling, a finished component may be passivated. This involves immersion of small components, or the flushing through of pipework, with nitric acid. This does not corrode the stainless steel nor remove the surface layer, but it helps to thicken, and so strengthen, the passive film.

Surface Finish on Stainless Steel

The surface finish on stainless steel is best expressed as the R_a value, which is the arithmetic mean deviation of the readings taken by a surface profile meter measured in microns. Expressed mathematically

$$R_a = \frac{1}{l_m}\int_{x=0}^{x=lm} |y|dx$$

An R_a value of less than 0.8 μm is regarded as adequate for most purposes. In some instances where high turbulence in the fluid product occurs, R_a values higher than 0.8 μm may be acceptable. A sheet that has been cold rolled will usually have an acceptable R_a. The requirement can also be achieved by polishing.

Elastomers

The following are suitable for use in the food industry:

Natural rubber,
Nitrile/butyl rubber.
Hydrogenated nitrile butyl rubber.
Ethylene propylene diene monomer (EPDM) is not resistant to oils and fats,
Silicone rubber, which is suitable for high temperature applications up to 180 °C, and
Viton (fluoroelastomer) which is suitable up to 300 °C.

Plastics

The following plastics are suitable in hygienic design:

Polypropylene,
Polyvinyl chloride (unplasticized),
Acetyl copolymer,
Polycarbonate, and
High-density polyethylene

Note that Teflon (polytetrafluoroethylene, PTFE) is generally porous and is not recommended.

Although these materials are suitable, the requirement of joining or welding them may render them unsuitable due to crevices formed during the joining or welding process.

Glass-reinforced plastics are generally unsuitable due to the presence of filaments of glass.

Other Nonmetallic Substances

Generally, wood is not suitable as a contact material or as a structural material in food processing plants. In certain

industries, such as wine and vinegar making, it is regarded as necessary. It is also suitable for cutting blocks. For anything else, wood should be avoided.

Coatings and adhesives are not generally used for contact areas. Epoxy and urethane-based coatings are used elsewhere. Where coatings are used they should be nonflaking and smooth.

Elements of Hygienic Design

Hygienic equipment may be divided into those items that can be cleaned in place and those items that must be dismantled for cleaning. Where sections of the equipment are cleaned or sanitized at a time when adjacent sections are being used for processing or product storage, there must be positive separation including an air gap between these adjacent sections. This is most often achieved in pipeline construction by the use of swing bends, splitter panels, and mix proof (double seat) valves.

Hygienic design requires that where pasteurized or sterilized product is contained in adjacent sections of the equipment to those containing service fluids or untreated product, the former must be maintained at a higher pressure than the latter. This is to ensure that should a leak occur between the sections, the leak will be from the treated to the untreated product.

Equipment that cannot be cleaned in place must be designed so that it can be inspected after cleaning. All surfaces should be visible.

Design of Product Contact Surfaces

Design of product contact surfaces needs to take the following into account: surface texture, cleaning and inspection, disinfection, pasteurization and sterilization, microbial ingress, draining, dead spaces, joints, coatings, internal angles, corners and grooves, seals, gaskets, *o*-rings and joint rings, fasteners, process flow disruption caused by intrusions, shafts and bearings, sensor and sensor connections, other connections, and openings and covers.

Surface texture: Cracks, pits, and folds are to be avoided and the surfaces should be smooth.
Cleaning and inspection: All equipment must be cleanable either in or out of place and where possible the surfaces should be capable of inspection after cleaning.
Disinfection, pasteurization, and sterilization: It should be possible after cleaning to disinfect, pasteurize, or sterilize product contact surfaces either in place or after disassembly.
Microbial ingress: Where necessary, equipment should be designed to prevent ingress of microorganisms.
Draining: Pipelines and equipment should be completely drainable. This generally requires the use of eccentric reducers in horizontal pipe runs. It also necessitates that certain positive displacement pumps be mounted with their inlets and outlets in the vertical.
Dead spaces: Dead spaces in pipelines and equipment should be avoided. In particular tee pieces for positioning of instruments should be kept as short as possible.
Joints: Permanent metal-to-metal joints should be fully welded. Nonpermanent (dismountable) joints should be flush. Screw threads should not be present in the product contact area as these cannot be easily cleaned.
Coatings: Generally, coatings should be avoided in product contact areas. Where coatings cannot be avoided, they should be nonflaking and smooth.
Internal angles, corners, and grooves: Sharp corners within machinery are difficult to clean. For this reason, all corners should be radiused. In general, grooves, where used, should be wider than their depth.
Seals, gaskets, o-rings, and joint rings: Elastomers have higher coefficients of expansion than steels. This should be taken into account in design. Repeated heating and cooling can otherwise result in sections of the elastomer breaking off in the product. Furthermore, product may be sucked in and trapped behind the seal during cooling.
Fasteners: Fasteners such as screws, bolts, and rivets should be avoided within product areas. During disassembly, some external screw threads may come into contact with product. These should be designed to be cleanable.
Intrusions: In certain instances intrusions such as springs cannot be avoided within the product contact area. If such intrusions cannot be avoided, they should be cleanable.
Shafts and bearings: Shaft entry points require the use of mechanical seals. Where possible, there should be movement of fluid in the seal area. There should be an air gap between the product area and any lubricated bearings.
Sensor and sensor connections: They should be installed in such a way that there are no dead spaces or crevices.
Other connections: All permanent and nonpermanent pipework connections to equipment should be designed to prevent ingress of contamination.
Openings and covers: Hinges that allow crevices for soil to accumulate should be avoided.

Design for Noncontact Surfaces

The design for noncontact surfaces is less stringent than for contact surfaces, particularly with regard to materials of construction. The following should be considered as general requirements:

Horizontal surfaces should be avoided. Supports should be so designed that soil will not remain on the surface.
Insulation on equipment and pipework should be fully sealed to prevent ingress of pests or contamination.
Equipment should be designed to prevent contamination with machinery fluids, such as lubricating fluids and sensor fluids. Where vapor is discharged from machinery, this should be vented outside of the factory area.

Designing for Ease of Maintenance

Wherever possible, equipment should be designed so that there is sufficient clearance between the equipment and the floor to allow adequate cleaning and maintenance. As a

general rule, a clearance of 300 mm should be allowed below major items of equipment.

Major items of equipment should be positioned a minimum of 500 mm from walls to allow maintenance, cleaning, and control of pests.

Pipelines and cable racks should be a minimum of 150 mm from walls to allow cleaning behind the racks.

Verification of Design

The hygienic design of equipment may be verified in one of three ways: the inspection of drawings of the machine, inspection of the machine itself, or by means of a practical test. The cleanability, pasteurization, sterilizability, and bacteria tightness may be practically tested. Methods have been documented by the European Hygienic Equipment Design Group.

As an example, assessment of the in-place cleanability of food processing equipment may be achieved by the following procedure under specific and controlled conditions. The cleanability of the test pieces is compared with a reference piece, which is a straight section of tube of similar diameter.

A thermophilic test strain, *Bacillus stearothermophilus* is prepared. This is added under controlled conditions to a soured milk soil.

The test piece and reference piece are cleaned, degreased and descaled, and sterilized. The equipment is then soiled with the soured milk soil under pressure and dried.

The equipment is then fitted to a test rig and washed under controlled conditions.

The test piece and the reference piece are filled or coated with molten agar and incubated. Yellow coloration is observed where there was residual soil on the test piece and this may be compared with reference piece.

Design of Key Items of Equipment

The requirements listed above are general requirements for all hygienic equipment. For certain equipment, there are specific requirements that supplement the general requirements. Some of these are given below. Requirements of hygienic design require attention to the mechanical design of surfaces, selection of standard items for particular tasks, confirmation of flow rates and physical parameters, and installation of equipment.

Pipelines

Pipelines are used to transfer a fluid or semi-fluid food ingredient or product or a service fluid from one area of the processing plant to another. The energy for the transfer is provided by pumps, gravity, or suction. Cleaning-in-place (CIP) pipelines are considered as a part of the process pipework system. This is consistent with the definition of a product contact surface.

The components of the pipeline system include:

Straight lengths of tube;
Flexible hoses;
Connection pieces in the form of bends, tees, and reduction pieces;
Valves of various types;
Instruments that impinge on the flow to a greater or lesser extent;
Joints either permanent (e.g., welds) or dismountable (e.g., unions); and
Pipeline supports.

For most hygienic applications within the food industry, pipelines should be constructed from stainless steel. The grades that are usually acceptable are AISI-304L and AISI 316L. Glass and copper piping are available as process piping. Plastic piping such as polyvinyl chloride (PVC) is also available and sometimes used. Although these materials may be suitable construction materials for food products, cleanable connections, and valves are often not available.

Stainless steel tubing most often used for hygienic duties in the food industry is seam welded and polished. A number of different dimensional standards are in existence. In particular, these include tube to the following standards:

DIN 11850,
International Organization for Standardization (ISO) 2037/ BS4825 Part 1, and
ISO DIN EN 1127.

In practice, the DIN 11850 standard is the most frequently used. However, dimensions of commercially available tubing vary considerably. It is important that misalignment or variation in dimension of tube components do not exceed 20% of the wall thickness.

As with other product contact surfaces, the pipework and fittings should have an internal surface roughness of 0.8 μm R_a maximum.

Flexible tubing in both plastic materials (notably PVC) and food grade rubbers (notably EPDM) are available. Neither ISO nor European Committee for Standardization (CEN) have standards either for the material or the dimensioning. Guidelines for the use of flexible rubber and plastic materials is given by the 3A Sanitary Standards Inc.

Schedule piping is generally unsuitable for food industry process lines because the surface is rough. In addition, threaded connections are not cleanable by CIP.

Pipelines should be drainable. A slope of 3° to the drainage point is recommended. This is equivalent to 1 in 20.

Standard dimensions for hygienic bends, tees, and reducers for use in conjunction with tubing with DIN 11850 are given in DIN 11851.

Permanent Joints in Pipework

Although expanded connection to dismountable joints was an accepted practice in the past, welded joints are now the norm. Welding is used to connect tube sections to bends, tees, reducers, valves, and also to dismountable joints (unions).

Welding of thin-walled tube may be manual or by means of an orbital welding machine. Tungsten inert gas welding procedures are used. The correct weld type is a butt weld without the use of filler wire.

The preparation of the weld requires proper attention to the cutting, surface treatment, and alignment. The face should

Table 2 Pipeline unions in common use

Type (common name)	*Dimensions of tube (International Organization for Standardization (ISO) – Imperial or DIN)*	*Expand on or weld on available*	*Nut type*	*Seal ring section*	*Standard applicable*
DIN	Either	Metric both Imp. w/o	Slotted	Half round	DIN 11851 Germany
DRT	Imperial	Both	Slotted	Rounded	DS 722 Denmark
SMS	Imperial	Both	Slotted	Square	SMS 1145 Sweden
ISS/IDF	Imperial	Both	Various	T shape	ISO 2853
Clamp Type	Imperial	Weld on	None required	Flat	ISO 2852

be cut exactly at right angles and burrs removed. The area 25 mm on either side of the weld should be cleaned and degreased. Misalignment of the tube ends should be less than 20% of the tube thickness. The gap between the faces should be less than 0.25 mm.

Before welding, the air must be purged with Argon. For short lengths of pipe, the ends of the pipe are sealed with tape or caps and the argon introduced from one end. For longer lengths of pipe, mechanical means of holding the inert gas such as plastic bladders are required.

Typical weld defects are the following: misalignment, cracking, porosity and inclusion, incorrect penetration, lack of sidewall fusion, and lack of gas shield. These will cause unhygienic conditions in the weld area.

Flow Rate in Pipeline Systems

Most thin food liquids (e.g., milk, beer, and cool drinks) should flow in pipelines at approximately 1.5 m s^{-1}. For thick liquids (e.g., tomato paste), this might reduce to as low as 0.2 m s^{-1}. Higher flow rates are important to ensure that dead ends in the pipeline are purged and that air is adequately removed from the system.

For CIP liquids will flow at 1.5 m s^{-1} minimum and flows of 2 m s^{-1} are usually specified.

Dismountable Joints in Pipelines

There are a number of standards for hygienic unions commonly in use. These are listed in Table 2.

It has been found that many of these unions are prone to problems of misalignment, leading to crevices.

For aseptic applications, unions to DIN 11864-1, 11864-2, and 11864.3 should be used. These are flanged, screwed, and clamp-type couplings using *o*-rings.

Reducers in Pipelines

Reducers for pipelines are either concentric or eccentric.

Guidelines for the use of reducers are:

Concentric reducers should be installed in vertical pipes.
Where drainage needs to be facilitated, eccentric reducers should be installed with the flat plane at the bottom.
Where air removal needs to be facilitated, eccentric reducers should be installed with the flat plane at the top. This applies particularly on the inlet to centrifugal pumps.
On the horizontal discharge of centrifugal pumps, eccentric reducers should be installed with the flat pane down.

Tee Pieces and Instrument Connections in Pipelines

Tee pieces often create dead legs in pipelines. If a dead leg is unavoidable, it must be as short as possible. For pipe diameters of 25 mm or more, tee pieces should preferably be less than 28 mm in length. For smaller diameter pipes, the dead leg should be less than the pipe diameter.

When dead ends cannot be avoided, they must be positioned so the flow is into the dead end. Dead ends that point vertically upward can become blocked with air. The result is that they will be almost impossible to clean. If steam sterilization is used, downward sloping dead legs may become filled with condensate and not be sterilized properly.

Swing Bends Splitter Panels

Where there is a risk of contamination or cross-contamination in pipelines, design should allow for a safety break between different sections of the pipeline system. Typically, this allows for a vessel or section of the plant to be cleaned while an adjacent vessel or section contains product. The safety break will be in the form of a swing bend, a splitter panel, or a double seat valve (Figure 1).

A swing bend is a section of pipe or key piece that can be removed to ensure a physical gap between adjacent sections of pipe. A splitter panel is more complex and allows connector pieces to be used to rearrange flows as required.

Design of splitter panel arrangements should ensure that connecting pieces do not allow the operator to make incorrect selections. The distance between the connecting points must be such that only the required connections can be made.

Design must ensure that cleaning fluid flows allow cleaning through each section of splitter panel.

Valves

Valves have a number of purposes in process plant operation. They provide for shut off or modulating control, as well as nonreturn (check), air removal, and safety functions.

Valves should be crevice free and cleanable and be without sharp edges, threads, or dead ends. Valves must, if possible, be drainable without dismantling. Seals must be properly designed and supported. Springs should, if possible, be avoided within the product area but if necessary, must be cleanable.

Sanitary butterfly and seat valves are acceptable for shut off duty. Nonsanitary ball valves must not be used in hygienic

Figure 1 A typical swing bend panel.

areas. During the operation of these valves, product will become trapped behind the ball. This area is not cleanable.

Seat valves include single seat valves and mix proof double seat valves. The area between the seats will be at atmospheric pressure during normal operation. Some valves compensate the pressure on the seat with a thicker shaft. The cleaning of the area between the seats is also important. Flooding the area by movement of either of the seats must be done at very low pressure. At this time, there will only be one seat separating the product from the CIP fluid (Figure 2).

Some valves will allow some leakage into the atmospheric area while the valve is activating.

Where aseptic conditions are required, the seats must be flushed (with a clean fluid such as condensate). Where contamination from outside is unacceptable, the shaft of the valve must be protected by a diaphragm, sterilizing fluid, or some other means.

In general, the operating of double seat mix proof valves should be automatic and without manual override.

Pumps

There are a wide variety of pump types that may be used in hygienic design. These may be divided into positive displacement and centrifugal pumps. Pumps provide a number of challenges both from design and selection points of view.

Hygienic Construction of Pumps

For rigidity the casings of pumps are commonly cast. It is important that the casting is machined to allow surfaces that

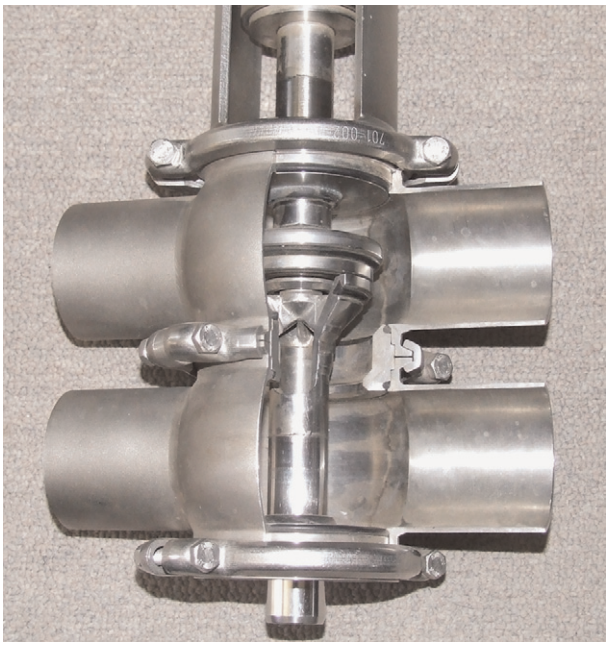

Figure 2 A cutaway of a leak proof valve in the open position.

are sufficiently smooth to be cleanable and to remove any crevices or sharp corners. Owing to the high fluid velocities that exist during the operation of pumps, it may not be necessary that all surfaces have a roughness, R_a less than 0.8 μm.

The seal area is particularly important. The mechanical seal relies on a fluid providing lubrication between a static and a dynamic surface. In the case of a single mechanical seal, this will be product. In the case of a double mechanical seal, this will be a service fluid, which will be at a higher pressure than the product and may then contaminate the product. In the case of the single mechanical seal, slight leakage of product will provide for cleaning of the seal area. In the case of the double seal, the choice of a seal fluid is very important.

Where electric motors are protected by shrouds, such shrouds should be easily removable for cleaning.

Selection of Pumps

Centrifugal pumps are selected whenever possible for hygienic duties. Positive displacement pumps do not usually provide sufficient fluid velocity to be used for CIP duties. Where necessary, a centrifugal CIP pump should be installed in parallel with a positive displacement product pump.

CIP return pumps should be liquid ring-type pumps. These are self-priming, thus ensuring complete emptying of the vessel being cleaned.

Industrial eccentric screw pumps are not suitable for food duties. The usual construction of this type of pump includes a hollow shaft where product can become trapped. Where (hygienic) eccentric screw pumps are used, they should be installed with the seal on the delivery end of the pump.

Where peristaltic (hose) pumps are used, those types that allow retraction of the shoes from the hose are preferable because they allow easy cleaning of the interior of the hose at CIP velocities.

Installation of Pumps

Pumps should be installed so that they are drainable. This requires mounting centrifugal pumps with the outlet in the horizontal plane. Lobe-positive displacement pumps should be installed with the inlet and outlet in a vertical plane.

Where (hygienic) eccentric screw pumps are used, they should be installed with the seal on the delivery end of the pump.

Positive displacement pumps require a pressure relief valve. This should be installed in such a way as to limit the dead ends between the delivery and suction of the pump.

Heat Exchangers

Plate heat exchangers are widely used in the food industry. Hygienic design requires that the flow rate of product within the machines is sufficient to prevent the formation of dead spaces or retention of air within the exchanger. This usually requires that viscous products flow in a single rising pass in the machine.

Flow rates that will be required for cleaning the machine should always be specified.

The gasket arrangement for plate heat exchangers must ensure that there is a double gasket separating the heat exchange fluids. This ensures a gap to atmosphere between the fluids.

Where possible design should ensure that the pressure on the product side of the machine or, in the case of a regenerative section on the treated side of the machine, be higher than the pressure of the fluid on the untreated product or service side.

Pasteurizers

Where heat exchangers are used for pasteurization or sterilization duties, the temperature probe should be so positioned that there is sufficient space between it and the diversion control valve to ensure that the valve will divert before untreated product passes it. The time taken by the temperature probe and valve operation may be several seconds when the plant is clean. This time will increase if there is any fouling on the probe.

Filling Machines

Liquid filling machines provide particular challenges for hygienic design.

Filling machines should, where possible, be designed so that CIP fluids can be returned to the CIP system. For reasons of safety and environmental management, dumping of CIP fluids at the filling machine is not an acceptable practice.

In the case of gravity filling machines, the velocities through the filling nozzles may not be sufficient to allow proper cleaning. In this case, machines should be designed to be disassembled for cleaning.

Equipment for Cleaning in Place

The CIP plant forms and integral part of any pipework system. Thus, the same criteria that apply to other parts of the system will apply equally to the CIP system.

It is preferable to separate cleaning of prepasteurization equipment and postpasteurization equipment.

Cleaning of Equipment for Dry Processing

Equipment may be designed for dry cleaning provided that the product does not present any risk of contaminating subsequent production, that it is nonhygroscopic, and nonsticky. In general, material must have a water activity below 60% for dry cleaning to be an option.

Infestation Management in Food Production Premises

CH Bell, The Food and Environment Research Agency, York, UK

Glossary

Diapause A state of arrested development, which can occur at any stage of the insect life cycle (depending on the species) in response to environmental cues, typically those heralding winter such as a lowering of temperature or shortening days.

Fumigant A chemical used in the gaseous stage for pest control, as distinct from insecticidal fogs (finely dispersed liquids) or smokes (finely dispersed solid particles), neither of which have any powers of penetrating commodities.

Instar Term given to the stages of larvae separated by the larval molts and numbered accordingly, the first instar being that emerging from the egg.

Nymph Term given to immature stages of arthropods developing without a complete metamorphosis in the life cycle, i.e., without larval and pupal stages.

Parthenogenesis Reproduction without mating, optional in a few insect species and in one or two cases the only reproductive process possible, there being a complete absence of males.

Introduction

Man is in direct competition with a variety of other species for food. These competitors not only consume the product but also contaminate the product with feces, exuviae or hairs, frass, and microorganisms. They can also alter the physical properties of the product by increasing temperature and possibly moisture content, and pose health threats by acting as vectors of pathogens and parasites. The importance of implementing effective pest management strategies cannot be overemphasized as the discovery of live insect stages or contaminants such as insect fragments and exuviae, or rodent hairs and droppings, has severe health and financial implications. Such incidents usually lead to the recall of the entire distribution of a particular product and may result in expensive litigation procedures, but potentially the greater financial loss is the longer term effect on consumer confidence in the product, which may never be fully restored.

In food production facilities there is a constant threat of pest populations becoming established as food is always present and there are many locations and access points for pests to enter and find refuges. Insect food pests are cosmopolitan whereas food facilities are twice as likely to encounter rodent problems in comparison with domestic premises and are legally bound to practice high food safety standards. Many procedures can be adopted to prevent pest access, to detect their presence on arrival, and to control infestations when they occur, and these are discussed in the following sections.

Pests of Food Processing and Production Facilities and the Risks they Impose

Any site where food is gathered, sorted, processed, or stored, is an attraction to wandering rodents, birds, insects, or mites whose lives depend on the successful location of food sources. Farmers, crop storage and distribution specialists, food processors, and retailers all need to take precautions to render their premises less vulnerable to exploitation by pests.

Although problems from vertebrate pests can largely be addressed by exclusion strategies, the same is not true for insects and mite pests, although exclusion strategies are still an important ingredient of pest management. Incoming supplies often introduce these pests and many species can become established in the fabric of the building, creating microclimates in harborages and wandering out to locate and feed on food residues. In warm climates population increase can be extremely rapid, and urgent action is needed to prevent the spread of infestation.

Vertebrate Pests

Rats, mice, sparrows, and pigeons are ubiquitous and major sources of contamination of food products in food processing facilities. They act as vectors of *Salmonella* and *Leptospira* bacteria, various viruses, rickettsiae causing Q fever and other pathogens. Weils disease caused by *Leptospirosis icterohaemorrhagiae* picked up by contact with rat excreta can be fatal, as can some cases of *Salmonella* food poisoning. Rodents also cause damage by the gnawing of wood, plastics, electric cabling, and even metal water pipes, sometimes with catastrophic consequences. For birds, netting of openings and needlematting of surfaces are well established, effective strategies to prevent ingress, but problems may still occur where continual access for transport is needed or weathering of buildings provides openings in inaccessible areas of roofing where birds such as sparrows, starlings, or pigeons can gain access.

Rodent proofing is a more complex problem as in addition to the obvious exclusion of ground level entry points,

attention needs to be paid to the drainage system as well as roofing eaves as rodents will ascend drain pipes, either internally or externally, and gain access to lofts and then through the whole building via heating ducts or electrical conduit routes. Access of rats from sewerage systems is also not an uncommon occurrence, so screens and other barriers should be in place and regularly maintained. The use of rodenticides for rat control requires the involvement of trained operators and even after careful observance of regulations is still a potential risk to nontarget organisms. Resistance has developed to anticoagulants such as warfarin, and now only second-generation compounds are in widespread use; difenacoum and bromadiolone are used both indoors and outdoors, and the more toxic brodifacoum and flocoumafen are used indoors only under carefully controlled conditions. Formulation and mixture with an appropriate food is of critical importance as baits are readily rejected. All baiting stations should be checked weekly and replaced if necessary.

Anticoagulants have always been less effective against mice because of avoidance following small intakes of bait, and given the loss of calciferol based on Vitamin D_3, no really effective bait is available. Physical traps are used to complement anticoagulant baiting strategies along with single-dose agents based on alphachloralose or zinc phosphide. In addition, sodium cyanide and aluminum phosphide formulations are available for fumigation treatment of rat harborages and burrows away from occupied buildings. However, none of these complementary measures can guarantee adequate control and for each facility an effective exclusion and trapping strategy is therefore a necessity.

Externally, access by rodents to buildings is prevented by clearance of all shrubbery and disused machinery from the vicinity of the exterior walls and the deployment of traps at regular intervals around the property and both inside and outside potential points of entry into buildings. A typical layout of trap deployment for a food facility is presented in Figure 1.

Insect Pests

Beetles

Coleoptera is the largest order of insects and there are more than 20 species of beetle or weevil of worldwide importance in the food industry. Table 1 lists some that are commonly associated with food processing facilities, together with their food preferences and requirements for rapid development. Many species are of tropical origin that have arrived and become established in heated premises since the advent of international trade. Others, such as the biscuit beetle and granary weevil, famous for infesting sailors' biscuits and grain

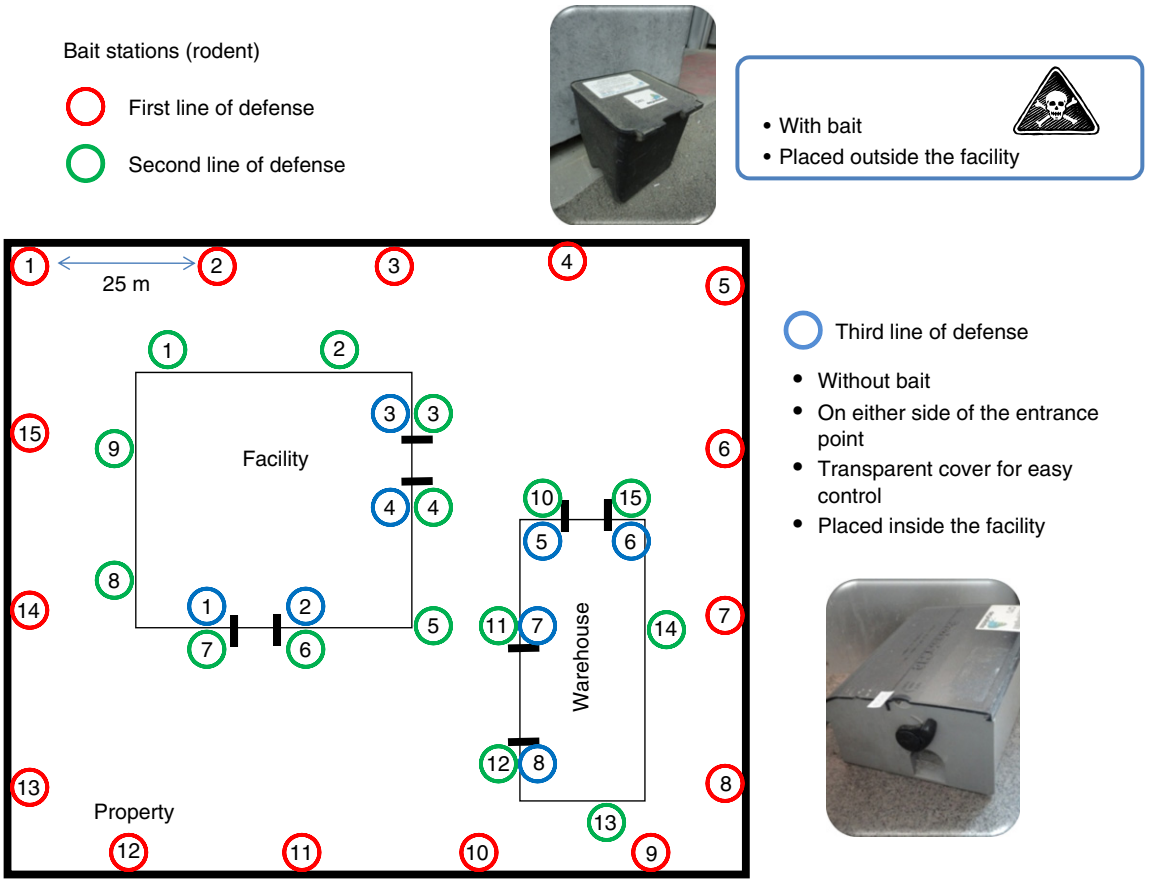

Figure 1 A typical layout of rodent traps for the protection of a food processing enterprise.

Table 1 A compilation of developmental requirements of beetle and moth pests often found in food processing facilities

Species	*Food preferences*	*Developmental range/optimum, and fastest multiplication rate*
Cryptolestes ferrugineus (Stephens) Rust-red grain beetle	Grains, flour, meals, oilseeds, dried fruit, and other dried vegetable materials	20–38 °C, min r.h. *c.* 30%/32–35 °C, 60-fold in 4 weeks
Cryptolestes turcicus (Grouvelle) Turkish grain beetle	Cereal products, notably wheat flour	*c.* 20–36 °C. min r.h. 50%/28–33 °C, *c.* 40-fold in 4 weeks
Gnatocerus cornutus (F.) Broad-horned flour beetle	Cereal products	15–35 °C, min r.h. 30%/*c.* 30 °C, *c.* 20-fold in 4 weeks
Lasioderma serricorne (F.) Cigarette or tobacco beetle	Cocoa, soybeans, tobacco, various cereals, spices, textiles, and many other products	22–38 °C, min. r.h. 30%/32–35 °C, 20-fold in 4 weeks
Oryzaephilus mercator (Fauvel) Merchant grain beetle	Oilseeds, dried fruit, nuts, and cocoa beans	17–38 °C, min 30% r.h./30–35 °C, *c.* 30-fold in 4 weeks
Oryzaephilus surinamensis (L.) Saw-tooth grain beetle	Cereal grains, cereal products, dried fruits, nuts, and some oilseeds	20–38 °C, min r.h. *c.* 40%/31–34 °C, 50-fold in 4 weeks
Rhyzopertha dominica (F.) Lesser grain borer	Cereal grains, flours, meals, and macaroni	19–40 °C, min r.h. 30%/32–35 °C, 40-fold in 4 weeks
Sitophilus granarius (L.) Granary weevil	Cereal grains (exclusively internal grain feeder)	15–30 °C, min r.h. *c.* 50%/25 °C, 15-fold in 4 weeks
Sitophilus oryzae (L.) Rice weevil	Cereal grains (exclusively internal grain feeder)	15–34 °C, min r.h. *c.* 40%/28–30 °C, 30-fold in 4 weeks
Stegobium paniceum (L.) Biscuit or bread beetle	Cereal products and many other dried vegetable and animal products	17–32 °C, min r.h. *c.* 60%/25–28 °C, 7.5-fold in 4 weeks
Tribolium confusum J. du Val Confused flour beetle	Cereal products, copra, groundnuts, sesame, and oilseeds	20–38 °C, min r.h. 20%/30–32 °C, 60-fold in 4 weeks
Tribolium castaneum (Herbst) Rust-red or red flour beetle	Cereal products, groundnuts, cacao, spices, dried figs and dates, copra, dried yam, palm kernels, nuts, and oilseeds	22–40 °C, min r.h. 20%/32–35 °C, 70-fold in 4 weeks
Corcyra cephalonica (Stainton) Rice moth	Cereals, cereal products, dried fruit, seeds, cocoa, and groundnuts	18–35 °C, min r.h. 50%/30 °C, 50-fold in 4 weeks
Ephestia cautella (Walker) Tropical warehouse moth, almond moth	Dried fruit, nuts, cereals and cereal products, cocoa beans, spices, copra, carobs, pulses, and dried vegetables	17–36 °C, min r.h. 25%/30–32 °C, 60-fold in 4 weeks
Ephestia elutella (Hubner) Warehouse or tobacco moth	Grain, cocoa, dried vegetable products	10–30 °C, min r.h. 20%/25 °C, 20-fold in 4 weeks
Ephestia kuehniella Zeller The Mediterranean flour moth or mill moth	Cereals, cereal products	10–30 °C, min r.h. 20%/25–28 °C, 50-fold in 4 weeks
Plodia interpunctella (Hubner) Indian meal moth	Dried fruit and nuts, cereals and cereal products, cocoa, oilseeds, confectionery, citrus pulp, dried vegetables, pulses, seeds, and carobs	18–36 °C, min r.h. 20%/30–32 °C, 50-fold in 4 weeks

supplies in the days of sailing ships, are native to temperate regions. Excavations of archeological sites have found dead specimens of the biscuit beetle in leather artifacts dating back to Roman times and in the remains of food left in tombs in ancient Egypt.

Stored-product beetles may be divided into those developing externally on semiprocessed foods and in finely divided products, and those internal feeders developing within whole seeds such as cereal grains and legumes. The latter group includes bruchids, weevils (Curculionidae), and grain borers (Bostrichidae), which cause problems because of infested raw materials and rarely become endemic in the structure of the food production facility. However, they are notoriously difficult to eradicate because they avoid detection and are protected from direct contact with control measures. The lesser grain borer and the granary and rice weevils occur as pests of rice and flour mills in this manner (Figure 2).

Those beetles feeding on semiprocessed materials or foods may again be divided into two groups, those with relatively short-lived adults (anobiids such as cigarette beetle, and dermestids such as Khapra beetle) and those whose adult stage may last a year or longer. In this latter group, including the *Tribolium* and *Cryptolestes* species, which are serious flour mill pests, and the *Oryzaephilus* (and also *Tribolium*) species (Figure 3) occurring widely in breakfast cereal, pet food, and confectionery manufacturers, both larval and adult stages actively feed on food products. It is this group that often establishes residual infestations in premises, entering cracks, crevices, and voids where food material escaping from processing machinery may accumulate. The long-lived adults seek out harborages from which they wander, often in a daily cycle, to scavenge for food and locate additional oviposition sites from which fresh infestations may start.

Despite their tropical origin and need of warm conditions for breeding, adults of many species of stored-product beetle,

(a) (b)

Figure 2 Two internally feeding grain beetles: (a) lesser grain borer *Rhyzopertha dominica* and (b) granary weevil *Sitophilus granarius*.

(a) (b)

Figure 3 Two externally feeding grain beetles: (a) saw-toothed grain beetle *Oryzaephilus surinamensis* and (b) rust-red flour beetle *Tribolium castaneum*.

both 'internal' and 'external' feeders, are highly cold tolerant and can readily overwinter in parts of the facility. Long-term infestation problems are revealed if the mealworm *Tenebrio molitor* L., at 12–17 mm in length the largest of all stored-product beetles, *Gnatocerus* spp. flour beetles, or spider beetles (Ptinidae) are present in the facility.

(a) (b)

Figure 4 Two moth pests of stored products: (a) brown house moth *H. pseudospretella* and (b) almond moth *Ephestia cautella*.

Moths

Most moth pests of food processing facilities belong to the family Pyralidae, although two oecophorid moths, the brown house moth *Hofmannophila pseudospretella* (Stainton) (Figure 4(a)), and white-shouldered house moth *Endrosis sarcitrella* (L.), are commonly encountered in damper, cooler situations such as mill basements and storage areas. Adult moths do not feed and damage is caused by the larval stage, which features a heavily sclerotized head capsule with biting and chewing mouthparts whereas the rest of the elongated body is flexible, unpigmented, and unsclerotized. In addition to the consumption and contamination of food, moth larvae produce silk from glands in the mouth, which builds into webbing that can obstruct machinery and clog production lines.

Oviposition in pyralid moths occurs mainly at dusk. The egg stage lasts a maximum of 7 days at 25 °C and there are five larval instars. The duration of the larval stage is influenced by temperature, food source, humidity, and whether or not a larval overwintering diapause occurs at the fifth instar. On completing their development, in preparation for pupation or diapause larvae spin a tough cocoon, which may be double layered. The pupal stage lasts about twice the duration of the egg stage at a particular temperature and adults are short lived, females laying most of their 2–300 eggs within 3 days.

The rice moth is a serious pest of mills in hot damp climates but can become established in heated premises anywhere in the world. The tropical warehouse or almond moth (Figure 4(b)) is the most frequently intercepted moth pest on food imports into the developed world and a common pest of food processing facilities. The Mediterranean flour moth is the principal moth pest of flour mills and bakeries in temperate regions of the world whereas the warehouse moth, as its name suggests, is largely confined to warehouse storage areas where it overwinters as a diapausing larva, able to tolerate temperatures down to − 10 °C. The arrest is triggered by late summer daylengths of less than 14 h. The Indian meal moth, perhaps the most versatile of all moth species in occupying niches in the food industry, can also overwinter as a diapausing larva. Details of the developmental limits and optima for each species are provided in Table 1, together with their food preferences.

Other Insects

Cockroaches, flies, ants, and psocids can also cause problems in food processing facilities. The principal cockroach pests belong to the genera *Periplaneta*, *Blatta*, *Blatella*, or *Supella*. Eggs are produced in capsules or oothecae, which remain attached to the female until deposited near a suitable substrate. Females produce a series of such egg cases, each containing up to 40 eggs. Nymphs can mature to adults within 12 weeks, though typically it takes several months for the life cycle to be completed. Because of their relatively large size and scurrying mobility cockroaches are the most noticed and hence most disliked of all insect pests. The American cockroach *Periplaneta americana* L. at approximately 3 cm in length is one of the larger species. All the pest species are of warm climate origin and though many are named after countries or regions, this does not necessarily reflect their true origin or range. Cockroaches are notable disease vectors and, particularly the German cockroach *Blatella germanica* (L.), can cause serious allergenic problems, besides contributing to the contamination and spoilage of food. With the notable exception of the Asian cockroach *Blatella asahinai* Mizukubo, few species fly and all need access to water. The waxy cuticle is more permeable to water loss than in more advanced insects and therefore wax-absorbing dusts can be effective means of enhancing control measures. Most species are cryptic, hiding from light in refuges with proximity to food sources. Though

some cockroaches respond at close range to aggregation pheromones, movements are more influenced by the physical environment than by odors, joints between walls and floors or shelving being favored for runs, particularly where open space is avoided. Complex or cluttered environments greatly contribute to their becoming established in premises.

Many different flies are hygiene threats in industry, including house flies, blow flies, fruit flies, and drain flies, each originating from different sources of hygiene failure. They can transmit many fecal and oral-borne pathogens. UV-light traps are widely employed to monitor and control flies in bakeries, restaurants, and food processing plants. The traps usually attract flies to an electrocuting grid but some incorporate a motorized glue paper roll, which allows the recording of catch over specific time periods. Siting of traps is important to minimize the chances of attracting insects from outside the building or contaminating food with biological material falling out from the grid or tray. Properly used, light traps can keep problems under control as long as adequate attention is also paid to remove potential sites for larval development.

Ants have caused problems at nearly every type of food production or processing premises at some time or other. Worker ants forage for food and carry it back to a central nest often at a considerable distance from the food source, leaving a chemical trail on the return journey. The result is that increasing numbers of workers appear in the facility, all following the same path. Two species regularly causing problems in houses, hotels, restaurants, hospitals, warehouses, and food production and processing facilities are the common black ant *Lasius niger* (L.) and the pharaoh's ant *Monomorium pharaonis* (L.). The latter can be controlled by insecticide baits based on juvenile hormone activity because, unlike the *Lasius* spp., there is usually only a single queen producing eggs in the nest.

Psocids are tiny, primitive insects feeding mainly on molds and decaying vegetable material in damp situations. They sometimes appear in huge numbers on food materials in commercial or domestic premises. The smallest opening in a food package can provide a point of entry for the minute nymphal stages. The commonest species is *Liposcelis bostrychophila* Badonnel, a rapid-moving, wingless, pale-colored insect approximately 1 mm long for which only females are known. Parthenogenetic multiplication can be rapid, but temperatures higher than 20 °C and high humidity are needed for egg production.

Mites

Mites, more closely related to spiders than insects and extremely small, utilize microenvironments of moderate temperature and raised humidity. The most important family associated with food storage problems is *Acaridae*, though the dried fruit mite *Carpoglyphus lactis* (L.) (Carpoglyphidae) and cosmopolitan food mite *Lepidoglyphus destructor* (Schrank) (Glycyphagidae) are also common pests. The life cycle includes a brief larval stage typically followed by three nymphal stages before the reproductive adult stage. Their rate of increase is unparalleled by any insect, with only 14 days being needed to complete development under optimal conditions and with a single female being able to produce 5–600 eggs. Eggs are cold tolerant and in some species development can proceed down to 5 °C, but in all species low humidity prevents development.

The flour mite *Acarus siro* L. is able to infest any food used by man if the local environmental conditions are suitable. The mold mite *Tyrophagus putrescentiae* (Schrank) is perhaps the most cosmopolitan mite pest of stored products, occurring in any product with a high fat or protein content. The tiniest opening permits entry of mites into packaged products and, once inside, an unpleasant taint is produced in the substrate. Many mites are also strongly allergenic.

Minimizing Pest Occurrence in Food Premises

It can be seen from the optimum requirements of insect pest species that the ideal environment of food processing premises should be low temperatures, low humidity, and an absence of accessible food sources. Unfortunately, none of these parameters can be maintained throughout a site and so there are always tensions in striving for the right balance between production needs and pest avoidance. Most food ingredients are vulnerable to pest attack, especially those with an equilibrium relative humidity greater than 65%, and the continual movement of commodities to and from trade premises poses a constant threat of importing pests. In nearly every country legislation demands the highest standards for any food product destined for human consumption, so the elimination of pest contamination of food is of paramount importance for the industry.

Effective control measures carried out at the source of raw ingredients provide a vital start to the chain that leads to the final processed product. Buildings need to be designed to avoid access points from outside, and doors and windows need to be precision-fitted and kept closed whenever possible. Recessing of external drain pipes prevents a ready access route to the eaves for rodents and wall surfaces should have a smooth finish both inside and outside. Internally, minimization of voids, ledges, crevices, or dead spaces is an important aspect at the planning stage as these provide locations where insect pests can establish refuges. Similarly, all machinery should be designed to avoid pest harborage. Rigorous, systematic cleaning of machinery and food production areas on a regular basis helps to prevent infestations becoming established. Timely and appropriate removal of accumulating waste and debris by vacuum cleaning, sweeping, and washing is another vital aspect to be built into management practice. Streamlining product distribution to reduce residence time in store and avoidance of storage alongside other less secure products are other useful measures to avoid problems. Care should also be taken to avoid stacking products in corners or near to walls, which reduces access for cleaning and provides harborages for pests.

Packaging can be an effective measure for reducing access of pests to food materials after processing, but standard carton designs generally provide little protection against stored-product insects. The spot weld glue patterns commonly used tend to leave channels through which smaller insect or mite stages can enter and does not provide a complete seal. Card, paper and cellophane wrappings are the least resistant to insect

penetration, whereas polycarbonate, some polyesters, polyurethane, and aluminum foil are much more resistant. All packaging is vulnerable to damage by rodents, and insects such as the lesser grain borer, biscuit beetle, cigarette beetle, and larger larvae of pyralid moth species possess powerful biting mouthparts and are also able to penetrate most films. Any measures to improve packaging design by reducing the chance of an incomplete seal, and removing joins, folds, and corners that are susceptible to mechanical damage or provide leverage for insect mouthparts should be implemented. Overwraps also improve resistance, particularly if applied as shrink-wraps fitting tightly around the package. A higher level of protection is provided by the 'form-fill-seal' machines employed in modified atmosphere (MA) or vacuum packaging. A heat-molded base tray is filled with product and a flat lid is heat-sealed across the top in the relevant atmosphere for the product.

All the above measures have economic implications and require there to be an adequate profit margin for the final product. Although the presence of pests can be minimized, total elimination of pest incidence can never be guaranteed. Therefore, there is a need for measures to detect pests at an early stage before they locate and damage the product. Meanwhile, research continues to refine methods of excluding and controlling pests, but problems can only be avoided if vigilance is maintained and management procedures are optimized and rigorously applied.

Pest Detection Strategies

A vital part of pest management programs is the early detection of pests. Many systems of trapping have been employed over the years, such as sticky papers and tapes, baited traps of various kind, and thin lines of grease or food-grade mineral oil around processing machinery or other vulnerable areas. The present focus is on the use of pheromones, the volatile chemicals released by insects themselves that function as a means of communication between individuals, and on food volatiles. Pheromones are particularly important for insect reproduction, both in long-range attraction of the opposite sex and in short-range mate location.

The chemical structure of pheromones has been analyzed for a large number of species of concern in stored-product protection. A list of some of the materials that have been isolated and identified is given in Table 2. There are two basic types of pheromone involved in pest detection systems: sex pheromones and aggregation pheromones.

Sex Pheromones

Sex pheromones are usually emitted by females to attract males for mating. They have been reported from many moths and certain families of beetles including Anobiidae, Bruchidae, and Dermestidae in which adults are relatively short lived and feed very little or not at all.

Sex pheromone activity may be exclusive to a single species but commonly may be shared between several related species. Thus, the sex pheromone, (*Z*,*E*)-9,12-tetradecadienyl acetate (TDA, also known as ZETA), is active not only against *Plodia interpunctella* but also against at least four other of its pyralid relatives. Similarly, the anobiids *Stegobium paniceum* and *Anobium punctatum* share stegobinone, and several *Trogoderma* spp. share (Z)-14-methyl-8-hexadecenal.

Aggregation Pheromones

Aggregation pheromones are usually produced by males and attract both sexes to suitable habitats and food sources where mating can then proceed. Beetles of the families Bostrichidae, Cucujidae, Curculionidae, and Tenebrionidae, which have adults that are relatively long lived, release pheromones of this type. Aggregation pheromones are also produced by some mite species. As with the sex pheromones, the aggregation pheromones may involve mixtures of materials and be shared by related species (Table 2).

Food Volatiles

A wide range of volatiles and aromas emitted from food materials are attractive to stored-product insects, and even plain water is effective in attracting moth species in dry conditions. Food bait traps have been employed widely in food processing facilities to monitor for the presence of beetle pests with varying degrees of success. The combined use of pheromones and food attractants offers the prospect of a monitoring system for a wide range of pests.

Pheromones as Pest Management Tools for Detection and Monitoring of Pest Populations

Pheromones are powerful attractants because of the extreme sensitivity of insects to these cues, and enable infestations to be detected at very low levels when visual or other forms of inspection are unlikely to be successful. This information is of critical importance for pest management programs in the food industry.

Pheromones are often complex mixtures of related compounds and their stereoisomers can evoke very different responses, so accurate identification, synthesis, and blending of the components is essential. Efficient delivery mechanisms for pheromones are also crucial. They must be adjusted to produce the appropriate concentration level for the species concerned, release the pheromone at a uniform rate, and have a capacity and operational life time consistent with the particular application. Trap design is important for both walking and flying insects. The distribution of traps in the treatment area is also a key factor. A vital issue after detecting the presence of insects in a facility is the accurate location of the infestation origin and to this end, spatial analysis of trapping data has proved useful, enabling precision targeting of infestation sources at an early stage.

Pest Control Strategies

Chemical Control Methods

Recently chemicals were the mainstay for pest control in the food and agricultural industry but various adverse side effects

Table 2 Attractants produced by some stored-product beetles and moths

Species	*Attractant*	*Details*
Lasioderma serricorne Cigarette beetle	Serricornin: (4,6-dimethyl-7-hydroxynonan-3-one)	Sex pheromone produced by females. Commercially available
Stegobium paniceum Biscuit beetle	Stegobinone: (2,3-dihydro-2,3,5-trimethyl-6(1-methyl-2-oxobutyl)-4*H*-pyran-4-one)	Sex pheromone produced by females. Commercially available
Rhyzopertha dominica Lesser grain borer	Dominicalure: (1-methylbutyl-(*E*)-2-methyl-2-pentenoate)	Aggregation pheromone produced by males. Commercially available
Cryptolestes ferrugineus Rust-red grain beetle	Ferrulactones I and II: [(*E,E*)-4,8-dimethyl-4,8-decadien-10-olide, and (3*Z*, 11 S)-3-dodecen-11-olide, respectively]	Two-component aggregation pheromone produced by males. Commercially available
C. turcicus Turkish grain beetle	(*Z,Z*)-5,8-tetradecadien-13-olide	Aggregation pheromone produced by males
Sitophilus granarius Granary weevil	Sitophilate: (1-ethylpropyl-2-methyl-3-hydroxy-pentanoate)	Aggregation pheromone produced by males. Commercially available
Sitophilus oryzae and *S. zeamais* Rice weevil and Maize weevil	Both species; Sitophinone: (5-hydroxy-4-methyl-3-heptanone, the 4*S*, 5*R* enantiomer)	Aggregation pheromone produced by males Commercially available
Trogoderma granarium Khapra beetle	92:8 mixture of (*Z*)- and (*E*)-14-methyl-8-hexadecenal	Sex pheromone produced by females
Carpophilus hemipterus Dried fruit beetle	(2,4,6,8)*E*-3,5,7-trimethyl-2,4,6,8-decatetraene and related compounds	Aggregation pheromone produced by males. Commercial lure available
C. dimidiatus Corn sap beetle	(3,5,7,9)*E*-6,8-diethyl-4-methyl-3,5,7,9-dodecatetraene	Aggregation pheromone produced by males. Commercial lure available
Oryzaephilus mercator Merchant grain beetle	*R* enantiomers of *Z*-3-dodecen-11-olide and *Z,Z*-3,6-dodecadien-11-olide	Aggregation pheromone produced by males. Commercial lure available
O. surinamensis Saw-toothed grain beetle	*R* enantiomers of *Z,Z*-3,6-dodecadien-11-olide, *Z,Z*-3,6-dodecadienolide and *Z,Z*-5,8-tetradecadien-13-olide	Aggregation pheromone produced by males. Commercial lure available
Tenebrio molitor Yellow mealworm	4-methyl-1-nonanol	Sex pheromone produced by females
Gnathocerus cornutus Broad-horned flour beetle	(*R*)-acoradiene	Aggregation pheromone produced by males
Tribolium confusum, *T. castaneum* Confused flour beetle, Rust-red flour beetle	Both species: 4*R*,8*R*-dimethyldecanal	Aggregation pheromone produced by males. Commercial lure available
Trogoderma spp. Warehouse beetles	(*Z*)-14-methyl-8-hexadecenal	Sex pheromone produced by females. Commercial lure available
Corcyra cephalonica Rice moth	Farnesal: (*E,E*-3,7,11-trimethyl-2,6,10-dodecatrienal)	Sex pheromone produced by males. Commercial lure available
Ephestia cautella Tropical warehouse or almond moth	ZETA: (*Z,E*-9,12-tetradecadienyl-acetate) and *Z*-9-tetradecenyl-acetate	Sex pheromone produced by females. Commercial lure available

of many compounds are causing concern. Hence, the more toxic substances have largely been replaced and the use of the remaining materials is being confined to application to surfaces or areas where subsequent contact with food or packaging is unlikely, thus avoiding the problem of chemical transfer to the food.

Insect Growth Regulators

In recent years the focus has been on developing compounds of highly specific action, based on the physiology of the pest. In this area, chemicals that act by disrupting insect life cycles have been developed. Insect growth regulators have come into use for the protection of many stored products such as grain. Methoprene, fenoxycarb, and hydroprene are commercially available juvenile hormone agonists. These cause the terminal disruption of insect development but have little or no mammalian toxicity. Their use in admixture on grain or on surfaces such as fabrics can confer protection against pests for over a year.

A second group of insect growth regulators, effective against Lepidoptera, act by interfering with the molting

hormone ecdysone with consequent prevention of normal metamorphosis. A third group, effective against cockroaches, act by inhibiting the synthesis of chitin, which also prevents normal molting of immature stages. Besides the very long life of the compounds, which can be an issue in international trade if residues are detected, another constraint for the use of insect growth regulators has been in integrated pest management programs where economically important biocontrol agents may be adversely affected.

Insecticides and Repellents

The use of insecticidal sprays and dusts has been a routine measure for spot treatment of localized infestations and surface application to areas of high risk. Organophosphorus and pyrethroid compounds remain in use for this purpose though registrations on some compounds are lapsing in many countries, restricting the choice available. Much effort is being placed on the search for new insecticidal compounds of botanical origin and some such as azadirachtin from the neem tree have joined with pyrethrins as registered botanical insecticides. The bacterial metabolite-based product, spinosad, is also now commercially available as a dust formulation. Dichlorvos space sprays have now been replaced by ultra low-volume (ULV) or aerosol treatments of synergized pyrethrins or pyrethroids in food production facilities, sometimes in mixture with an insect growth regulator such as methoprene, but are only effective against flying insects. The field of insect repellency is one still under investigation, a nontoxic, nonspecific insect and mite repellent being the goal.

Fumigants

For many years fumigants have been relied on for the whole site treatment option when infestation problems get out of control. Flour mills and chocolate factories would typically rely on an annual fumigation by a licensed company with registered pest control operators. To be effective the fumigant had to be suitable for rapid and even distribution throughout the treatment area and in order to minimize production downtime it had to be effective against pests within 24 h. The first fumigant in widespread use for treatment of structures, hydrogen cyanide, was replaced in the 1960s by methyl bromide, which, though less of an acute toxic risk to operators was still a highly toxic compound. It was nevertheless extremely effective when used in a well-sealed structure, being an excellent penetrant of voids containing food residues and highly toxic to all pests, achieving control within 24 h.

Methyl bromide, listed as an ozone-depleting compound under the Montreal Protocol in 1992, was phased out from all but a few specialist uses in non-Article 5 (developed) countries in January 2005. Developing countries can continue using methyl bromide until 2015, beyond which their use also will be confined to a few quarantine-related circumstances. The only other fumigant widely registered at the start of this century was phosphine, which is an excellent fumigant for commodities in store where the longer residence times permit the long exposure periods (up to 3 weeks at 15 °C) required for effective control of pests. The gas is released from aluminum or magnesium phosphide formulations on contact with atmospheric moisture. Phosphine is, however, difficult to use in food processing premises because of its corrosive properties against electronic equipment and the long exposure times required, especially at temperatures below 25 °C.

Sulfuryl fluoride (trade name Profume), has been registered for use instead of methyl bromide in empty flour mills, starting in Switzerland in 2003, and now in many European countries, Australia, the US, and Canada, but concerns over its global warming potential and the significance of fluoride residues has limited registrations for use on food materials or in structures where raw or processed food is present. Its use also requires additional heating as insect eggs are tolerant and would otherwise require long exposure times for control. With increasing pressures for the safe and effective use of chemicals, any move away from heavy reliance on them is obviously desirable.

Physical Control Methods

There are opportunities and limitations for the use of physical control methods in structures. For example, the use of MA techniques for space treatments is restricted to specialist chambers because while buildings can be sealed sufficiently for fumigation, they cannot be sealed to the much higher standard required for MA applications (very high CO_2 or very low O_2 levels). Scope for use of sonic, microwave, or radiation technologies is also very limited. Nevertheless, several physical methods are of value in the controlling of pest outbreaks.

Heat

For the food processing industry, the downtime and production loss arising from whole site treatments to combat pest problems has restricted control options to those which act most rapidly and effectively. Heating to 47 °C or above results in rapid immobilization and death of insect and mite stages within a few hours. Heat is thus one of the few options offering a similar rate of action to fumigation with methyl bromide. The principal problem for heat disinfestation, though, is the planning of heating requirements and heat source deployment to obtain a uniform heat profile throughout the structure without causing high localized temperatures, which would cause damage to structural or electronic components. The temperature of air from heaters needs to be limited to 65–70 °C to avoid activating sprinklers or causing expansion and cracking; and air speeds should not exceed 5 m s^{-1} to avoid dust explosions. Structural heat treatment involves raising the building temperature to 50–55 °C at a rate of 5 °C h^{-1}. Sufficient heaters to ensure that 50 °C is reached within 6–8 h are required. Spot heat treatments may also be carried out where a zone of a processing facility or an item of machinery is heated to above 50 °C with a forced hot air stream.

Much progress has been made using a combination of heating strategies, often in conjunction with the use of inert dusts to treat areas difficult to heat such as voids and cracks, a procedure first tested in Canada and further developed in Europe. Residual infestations in deep-seated harborages in the basement or elsewhere remain a particular problem. It must be remembered that the target temperatures for control must be reached at the point where the insects reside in the

structure, a process that may take 24 h, and that the presence of protective material such as food residues can lower the temperature experienced by the insect.

Cold

The intense periods of winter cold have long been used by millers and warehouse keepers in Canada and the Northern USA for a freeze-out of pests, and there is seldom any need for additional control methods in the first few months after treatment. Cold can also be used as a spot treatment by the injection of liquid nitrogen into confined spaces such as wall voids. However, insulation in walls can affect cold distribution, leaving protected warm spots. Also, surfaces can be stained and warping of wooden structural components may occur.

Most insects succumb to exposure at temperatures below − 10 °C within a few days whereas below 10 °C insect reproduction ceases and population levels of most pests decline. The cold resistance of the pest depends on the stage of development: eggs are more sensitive, and adults or larvae, especially those in diapause, are the most cold tolerant. Nevertheless, adults of most species can survive temperatures around 4 °C for many months and so can readily overwinter in buildings in temperate climates. In consequence, cold exposure requires very long holding times to be effective and this is rarely achievable in the production areas of food processing facilities. Nevertheless, the use of designated cold storage areas for incoming ingredients is a widely practiced measure in many industries in spite of the high capital investment required.

Impaction

Many situations in which agricultural products are mechanically conveyed during food processing offer the opportunity for control of insects by shock, abrasion, and impaction. The principle was developed more than 70 years ago for use in the flour milling industry and impaction machines such as the 'Entoleter' became a routine fixture in facilities such as flour mills. In the Entoleter, flour falls between two rapidly spinning disks. Centrifugal force pushes the flour to the edges of the disks where it impacts a row of steel pegs mounted on the rims, and is thrown against the outer steel casing before falling into the basal receiving hopper. The material passing through the Entoleter thus encounters two major impactions and this effectively controls all free-living insect stages. Impaction machines can also kill a high percentage of insects such as weevils developing inside cereal kernels.

Inert Dusts

Inert dusts cover a wide range of materials including clays, sands, ashes, diatomaceous earths (DEs; fossilized remains of diatoms consisting mainly of silica with small amounts of other minerals), silica aerogels and nonsilica dusts, such as phosphate and lime. Inert dusts have a long history of use for grain protection. Their lethal action against pests is caused by dehydration, the cuticular waxes being adsorbed by the desiccant on prolonged contact. Abrasion of the cuticular joints in mobile stages may also be a contributory factor but recent formulations are being designed to minimize their abrasive properties to protect conveying machinery.

Inert dusts are registered in many countries for treatment of grain and pulses against insect pests and for use as sprays applied to the fabric of food premises to minimize residual infestation and migration of pests. They form a useful part of integrated pest management (IPM) strategies providing an alternative to chemical protectants for pest control. Some formulations are accepted as suitable for use on foods certified as 'organic' in some countries. DEs are widely used as food and processing additives.

Irradiation

Irradiation from a cobalt-60 source has been used primarily as a bactericide for many years for treatment of some commodities, mainly spices, and also for dried and fresh fruit, potatoes, onions, and poultry. It requires proximity to a commercial treatment source to be practical and consumer acceptance has limited its widespread use.

Exposure of a commodity to irradiation may be by continuous flow through an irradiator or by batch treatment of cartons by pallet load. A 10-MeV electron beam unit has also been in use for certain applications but the reduced safety concerns are outweighed by the very low penetrability of commodities, restricting the form in which they can be presented for treatment.

Biological Control Methods

Many organisms are known to attack, infect, or parasitize stored-product insects some of which are listed in Table 3. The use of such organisms in food processing facilities is limited by the need to ensure that their presence does not itself lead to problems as discovery of any insect fragments in a finished product is unacceptable. The need for a constant low population level of the host also rules out many applications. Nevertheless, opportunities exist for deployment of parasitoids and predators in receival facilities to deal with background pest levels in empty stores as an alternative to cold storage or fabric treatments with insecticides. Also pathogens can be used in conjunction with attractants to provide a control system for flying pests, or as pest-specific additives to bulk commodities such as cereals.

Use of Pheromones for Population Control

Pheromones can be used to provide the attraction agent for mass trapping to physically remove insects, by disrupting mating to prevent breeding, or by acting as an attracticide to a point where pesticides, pathogens, or sterilizing agents are used as the control agent. The technique is used to reduce pest populations to manageable levels rather than eliminate them and is most suited to confined areas. It is most effective at relatively low starting population densities. Aggregation pheromones are more effective than sex pheromones because both sexes are attracted to the traps. Nevertheless, mass trapping has been successfully trialed with sex pheromones against moths in flour mills to reduce pest populations to a constant low level. The pheromone trap is baited with an insecticide such as cypermethrin or another quick knock-down agent or arrestant to retain the attracted moth. Alternatively, a

Bacillus thuringiensis and Bacillus cereus	Entomopathogenic bacteria	*L. serricorne*, Pyralid moth larvae
Polyhedrosis viruses	Larval pathogens	Pyralid moths
Beauveria bassiana (Balsamo) Vuillemin	Entomopathogenic fungus	*Sitophilus* spp., *Tribolium* spp., *Oryzaephilus* spp.

pathogen source may be incorporated to disseminate disease through the pest population.

Another approach is to use sex pheromones to disrupt mating. It is achieved by flooding the environment with the sex pheromone of the target species so that mating behavior is disrupted by false trail following and sensory fatigue so that mate location and reproduction is minimized. The dispensers need to release adequate amounts of pheromone over a prolonged period and treatments need to be applied before emergence of the target species over a wide area for successful results.

IPM

IPM is a pest risk-management approach combining a selection of the methods described above in a way that addresses socioeconomic, health, and environmental risks in a sustainable manner while maintaining an acceptable level of productivity. It is highly information based, integrating knowledge about the pests with knowledge about the facility to avoid pest problems and maintain high product quality. For successful implementation, adequate training of industry staff on the tools employed is necessary. In many cases pest management is contracted out by companies to a registered pest control company with specialist trained staff, but for any management strategy to work the minimum requirement is that a weekly inspection of facilities, and particularly trapping and baiting locations, is carried out and coupled with a clearly defined course of action if there is evidence of pest presence.

Emerging Threats for the Successful Maintenance of Pest Management

The big issue regarding the continued successful use of chemicals for control of stored-product pests is the development of resistance. Pests have become resistant to insecticides, insects growth regulators, fumigants such as phosphine and even to some bacteria-based sprays. The problem is often compounded by cross resistance to other groups of compound.

Adoption of alternative strategies that avoid chemical control tends to be costly and labor intensive. This places a burden on the manufacturer that cannot always be passed on

to the consumer and can result in lower standards of pest management than when chemicals were in wider use. A related effect that is often overlooked is that the reduced market for chemicals results in products being withdrawn from the market, particularly when an existing compound comes up for regulatory review on a prefixed timetable. Product registration is required in most countries for each chemical intended for use in pest control. Significant efforts have to be undertaken by commercial companies to conduct research, assemble, and submit a registration package to obtain a label for legal use of a new compound or to extend the use of one that is under review. The registration process is very costly with lengthy delays and requires that the company developing the product has the relevant technically qualified personnel. Applications are often returned with requests for more data, increasing the expenditure. Where the company can only see a small market in a particular country or application, they are unlikely to proceed with registration. This can result in the disappearance of existing compounds from the market, reducing the options for pest control.

Although some problems remain, pest management standards in the food industry have never been higher and research is actively in progress to keep abreast of developments as new products and procedures, and new pests, come into being.

Personal Hygiene and Employee Health

ECD Todd, Ewen Todd Consulting LLC, Okemos, MI, USA

Glossary

Antiseptic A substance that inhibits the growth and development of microorganisms, typically used as a topical agent for application to the skin.

Asymptomatic shedders Food employees who do not exhibit the symptoms of foodborne illness, but excrete a pathogen; these are typically only identified during a foodborne illness outbreak investigation through microbiological testing.

Food workers Individuals who harvest, process, prepare, and/or serve food, i.e., across the whole food chain to retail/food service; this category is broader than that of 'food handlers', who typically work in food-service establishments, typically foodservice; however, the two terms are used interchangeably in the literature.

Nasopharyngeal secretions Secretions from the area of the upper throat that lies behind the nose.

Oropharyngeal secretions Secretions from the area of the throat that lies behind the mouth.

Food Workers as Cause of Enteric Illness

Outbreaks Contributed by Food Workers

Outbreaks of foodborne illness involving infected food workers in many food-service settings have been widely reported, with some resulting in many cases and deaths. A recent review of such outbreaks by Greig et al. (2007) and Todd et al. (2007a, b, 2008a, b, 2009) shows that food workers have been responsible for foodborne disease outbreaks for decades, and there is no indication that these are diminishing. These authors collected 816 reports comprising 80 682 cases from events spanning 1927 to the first quarter of 2006, with most of these occurring in the last three decades. Most of the outbreaks reviewed were from the US, Canada, Europe, and Australia, with relatively few from other parts of the world, indicating a skewed set of data because of the availability of relevant information in the published literature or through personal contact. These outbreaks were caused by 14 agents: norovirus, Norwalk-like viruses or probable norovirus (338), *Salmonella enterica* (151), hepatitis A virus (84), *Staphylococcus aureus* (53), *Shigella* spp. (33), *Streptococcus* Lancefield groups A and G (17), and the parasites *Cyclospora*, *Giardia*, and *Cryptosporidium* (23). It appears from these data that the frequency of streptococcal, staphylococcal, and typhoid outbreaks has diminished over time and those involving hepatitis A virus (HAV) have little change, but those with norovirus and maybe nontyphoidal *Salmonella* is increasing. Norovirus terminology changed over the time of the reporting of the 816 outbreaks and it is only in the more recent years that the agent could be definitively be called norovirus; thus, many older reports used terms such as Norwalk or Norwalk-like viruses (called here probably norovirus). Table 1 shows the main agents implicated in food worker outbreaks and their frequency as the cause of these outbreaks. The outbreaks involving bacterial

Table 1 Pathogens identified in outbreaks where food workers have been implicated

Agents	*Frequency of worker infection leading to outbreaks*
Bacterial	
Campylobacter jejuni	Rare
Escherichia coli O157:H7 and other VTEC/STEC	Rare
Salmonella spp (nontyphoidal)	Frequent
Salmonella Typhi/Paratyphi	Occasional
Shigella spp.	Occasional
S. aureus	Frequent
Streptococcus pyogenes Group A	Rare
V. cholerae	Rare (in most countries)
Yersinia enterocolitica	Rare
Viral	
Hepatitis A virus	Frequent
Norovirus	Frequent
Rotavirus	Rare
Parasitic	
Cryptosporidium parvum	Rare
Cyclospora cayetanensis	Rare
Giardia lamblia	Rare

Abbreviations: VTEC, verotoxin-producing *Escherichia coli*; STEC, Shiga toxin-producing *Escherichia coli*.

pathogens were typically associated with potentially hazardous foods that allowed growth. Specifically, multiple foods and multi-ingredient foods were identified most frequently with outbreaks, perhaps because of more frequent hand contact during preparation and serving.

In some cases, the worker may have been a victim rather than the cause of the infection, becoming ill at the same time as the customers or later. In other situations, the worker blatantly disregarded normal hygienic practices, which may have been a result of inappropriate individual actions or the accepted way of doing business in the establishment. Practices leading to these actions have previously been documented, such as workers being asymptomatic and excreting the pathogen unknowingly while working, or they continued to prepare food when it is obvious to them, and sometimes others, that they were ill with a high probability of contaminating food. This seems to be in contrast to the 1988 World Health Organization study conducted by an international working group, which concluded that asymptomatic carriers of nontyphoidal *Salmonella*, *Shigella*, *Vibrio cholerae*, and enteric viruses pose only minimal risks as long as good hygiene is practiced (*55*), although it is recognized that proper handwashing does reduce the microbial load on fingers and palms.

Some of the outbreaks were very large; 11 involved more than 1000 persons, 4 with more than 3000 ill. The larger outbreaks tended to be extended over several days with a continuing source of infections, such as at festivals, resorts, and community events, or the contaminated product had been accessed by a large number of customers. There were five outbreaks with more than 100 persons hospitalized, with attack rates ranging from 9.9% to 100%. However, overall, the hospitalization rate was low (1.4%), and deaths were rare (0.11% of the 80 682 cases). Many of the deaths were associated with high-risk persons (i.e., those who had underlying diseases, malnutrition, or both, as in a refugee camp, or young children), but a few occurred with apparently healthy adults.

Food Operations and Foods Implicated

An analysis of the settings for the food worker-related events showed that most of the outbreaks came from food-service facilities (376 outbreaks (46.1%)), followed by catered events (126 outbreaks (15.4%)), the home (83 outbreaks (10.2%)), schools and child care centers (49 (6.0%)), and health care institutions (43 outbreaks (5.3%)). However, many cases resulted from relatively few outbreaks (<30 each) associated with community events (9726), processing plants (8580), mobile/temporary service (5367), and camps/armed forces (5117). The single most frequently reported setting was restaurants, with 324 outbreaks and 16 938 cases. Improper hygienic practices in homes, on picnics, or at community events accounted for 89 of the 816 outbreaks. Case numbers in outbreaks in homes or at community events are probably underestimated because they are less likely to be reported than those involving commercial establishments. Sixteen outbreaks occurred where food, primarily produce, was harvested and shipped from one country to another.

Sometimes the presence of an infected worker preparing food was only one of several factors contributing to the outbreak. Large outbreaks frequently occurred because of the continual exposure of large groups to a pathogen, either because the source had not been identified soon enough or because control measures had been insufficient to eliminate the agent, such as at refugee camps or large outdoor events. However, in several other large outbreaks, the amount of contaminated food was so great that thousands of persons were exposed by the same batch of food; this occurred with frosting on cakes, imported raspberries used in a variety of dessert dishes, and items served at large receptions or commissaries. The agents in large outbreaks also tended to be highly infectious, such as *Shigella* or norovirus. Because ready-to-eat (RTE) foods are not further processed or cooked, subsequent contamination by infected food workers frequently led to outbreaks. These included produce and baked goods, as well as beverages that would not normally allow the growth of pathogens. However, many of these were of viral origin with sufficient particles to cause an infection without further multiplication. Food-service outlets, such as restaurants, and catering companies, and schools that served large numbers of patrons, were the most frequent settings implicated. However, episodes linked to bakeries, hospitals, camps, homes, and church meals highlighted the necessity for those who prepare and serve meals in these operations to excuse themselves from food preparation if they are ill or exposed to infected individuals. There were 18 outbreaks associated with commercial travel in air flights, trains, and cruise ships over several decades, although only the last seems to be a major concern today. Because the patrons have limited choices in these carriers and are confined within their means of transportation, the impact of illness is often quite dramatic and newsworthy. However, the role of the infected food worker in outbreaks on cruise ships is difficult to determine, because the passengers may be as much a source of infectious agents, such as norovirus, as the crew members.

Factors Contributing to Outbreaks

The most frequently reported factor associated with the involvement of the infected worker was bare hand contact with the food, followed by failure to properly wash hands, inadequate cleaning of processing or preparation equipment or utensils, crosscontamination of RTE foods by contaminated raw ingredients, and (for bacterial pathogens) temperature abuse. Many of the workers were asymptomatic shedders or had infected family members and/or used improper hygienic practices. Outbreaks were sorted into categories based on how many workers were implicated, the origin of the infective agent (outbreak setting or off site), the degree of certainty that the workers were the cause or were victims, whether or not the workers denied illness, the ability of the agent to grow in the food, whether only the workers and not the patrons were ill, and whether patrons were more responsible for their illnesses than were the workers. The most frequent scenarios were (1) a single worker causing an outbreak by directly infecting patrons; (2) an infected worker fecally contaminating foods that were then temperature abused, leading to an outbreak; and (3) multiple workers linked to an outbreak, but with no clear initiating source.

Sources of Pathogens

These include vomitus, diarrhea, and nasopharyngeal or oropharyngeal secretions, often being transmitted to food or food contact surfaces. The likelihood that workers cause illness in patrons and fellow workers depends on several factors: the numbers of organisms required to initiate an infection, the site of colonization, and the length of their carriage in infected persons. Pathogens of nose, throat, skin, or fecal origin are most likely to be transmitted by the hands, as hands are the parts of the body that frequently touch the mouth, skin, and anal areas. The pathogens most likely to be transmitted by food workers are norovirus, HAV, *Salmonella*, *Shigella*, and *S. aureus*. Unfortunately, such pathogens can be in high numbers in or on the body during an infection. This is particularly true for intestinal infections, where levels can reach 10^{11} infectious cells or particles per gram of feces, although 10^5–10^9 g^{-1} is more frequent. Some pathogens appear to be able to infect at doses as low as 1–100 units, including viruses, parasites, and some bacteria. Although parasitic foodborne episodes of illness are rare, the dose for *Cyclospora*, *Cryptosprodium*, and *Entamoeba* may be as low as one cyst/oocyst. Based on outbreak data and other infectious disease studies, other pathogens with low minimum infections doses are *Campylobacter*, *Escherichia coli* O157:H7, *Salmonella* Typhi (and a few other *Salmonella* serotypes), *Shigella dysenteriae*, HAV, norovirus, and rotavirus (<100 cfu or particles). Interestingly, only rarely have *Campylobacter*, *E. coli* O157:H7, and other *E. coli* serotypes been implicated in food worker associated outbreaks. Infectious dose data for pathogens transmitted by food workers and implicated in outbreaks are shown in Table 2.

Table 2 Infectious dose data for pathogens implicated in outbreaks transmitted by food workers

Pathogen	*Infectious dose from volunteer studies (cfu/viral particles)*	*Infectious dose from outbreak data and estimates (cfu/viral particles)*	*Levels in outbreak food samples (cfu/g or ml)*	*Pathogen implicated in food worker outbreaks*
Campylobacter jejuni	10^3			Rare
Enteropathogenic *E. coli* (EPEC), Enterotoxigenic *E. coli* (ETEC) Enteroaggregative *E. coli* (EAEC)	10^6–10^{10}	$>10^2$ (estimated)		Unknown or rare in developed countries, maybe more frequent in developing countries
Enteroinvasive *E. coli* (EIEC)		10^0–10^3 (estimated)		Unknown, maybe in developing countries
Enterohemorrhagic *E. coli* (EHEC)		10^0–10^2 (estimated)		Occasional
E. coli O157:H7		10^0–10^4	0.04–93	Occasional
E. coli O111			0.1	Not known
Salmonella Typhi	10^5–10^9	10^1–10^3 (estimated)		Occasional but declining
Salmonella spp. (nontyphoidal)	10^5–10^9	$<10^1$–10^{11}	0.03–$10^{4.5}$ mostly low	Frequent
S. dysenteriae	$<10^1$–10^4	$\geq$1(estimated)		Probable in developing countries
Shigella flexneri and *S. sonnei*	10^2–10^3			Occasional
S. aureus		$<$1–5 μg enterotoxin produced with $\geq10^5$ cells	10^5–10^8	Frequent
S. pyogenes (Group A)		$\leq10^3$ (estimated)		Occasional
Streptococcus Group D		$>10^7$ (estimated)		Rare
Vibrio cholerae O1 and O139	10^3–10^{11}	10^2–10^3		Likely in endemic areas
V. cholerae non-O1	10^6–10^9	10^6–10^{11} (estimated)		Not known
Y. enterocolitica	10^9	10^2–10^9 (estimated)		Occasional
Hepatitis A virus		10^1–10^2 (estimated)		Frequent
Norovirus	$\leq10^4$–10^8	10^1–10^2 (estimated)		Frequent and increasing
Rotavirus	10^1–10^4	10^1–10^2 (estimated)		Occasional
Cryptosporidium parvum	10^2–10^3 oocysts	10^0–10^1 oocysts	$<10^2$ oocysts	Rare
Cyclospora cayetanensis	Unknown (up to 10^4 oocysts did not cause symptoms)	Assumed to be low		Not known but probable
Entamoeba coli	1 cyst	1 cyst (estimated)		Not known, but probable
Giardia lamblia	10^1–10^2 cysts	1 cyst (estimated)		Rare

Table 3 Infection characteristics of foodborne pathogens transmitted by infected food workers

Pathogen	*Incubation period (days)*	*Duration of illness (days)*	*Carriage rates reported (%)*	*Postsymptomatic shedding (days)*	*Percentage of individuals who excrete the pathogen but are asymptomatic*
C. jejuni	2–5 (1–10)	2–10	0–38% of GI[a] cases, 0.5–0.9% asymptomatic controls	2–9 weeks; if untreated, relapses occur in 20% of patients	0.1–77
Enterohemorrhagic *E. coli* (STEC[b], VTEC[c]); *E. coli* O157:H7	1–10	5–21	0.0–0.6% (verotoxin in 2.1% of GI cases), 0.0% of asymptomatic controls	<10–62	Up to 53
E. coli non-O157 VTEC/ STEC			0.2–8.6% of GI cases, 0.5–1.0% of controls		0.2–1.2
Enteroaggregative *E. coli* (EAEC)			2.9–15% of GI cases, 0.5–1.8% of asymptomatic controls		2–9
Enteroinvasive *E. coli* (EIEC)	0.5–3	3–>7	0.4–1% of child diarrheal cases		
Enteropathogenic *E. coli* (EPEC)	0.5–3	3–14	0.1–20.7% of GI cases		1.2 (children)
Enterotoxigenic *E. coli* (ETEC)	0.5–3	3–14	0.6–32% of GI cases, 0% of asymptomatic controls		1.6–2.5 (children)
Salmonella Typhi/ Paratyphi	Typhi: 4–60 Paratyphi: 1–10	Many days to weeks	37% with typhoid fever symptoms; 4% chronic carriage, higher in older age groups	>7 years; more women than men as chronic symptomatic carriers occur, more women than men	
Nontyphoidal *Salmonella*	0.5–3	3–5	• 0.0–16% of GI cases • 0.2–4.6% of asymptomatic controls	4 weeks–12 months (up to 22 weeks in infants), 0.5% of asymptomatic controls excrete at 12 months	0.23–18.7

Shigella spp.	0.5–6.1	2–90	0–52% of GI cases, 0.0% of asymptomatic controls	Up to 17 months	
S. aureus	0.5–8 h,	1–2	0.1–0.4% of GI cases, 0.1–0.2% of controls (fecal counts $>10^6$/g)		
S. pyogenes				21–60	20–65
V. cholerae 01	0.25–5	3–9	33% of GI cases	2 weeks–7 months	4
V. cholerae non-01	5.5–96 h	3.5–48 h			4
Y. enterocolitica	1–11	1–3 weeks	0.1–3.4% of GI cases, 2.4–3.1% of controls (*Yersinia* spp.)	Intermittent carriage by asymptomatic children up to 14 weeks with pathogenic strains	0.2–6% with pathogenic strains
Hepatitis A virus	10–50	2–3 weeks (months)	9.7/100,000	21–6 months	8.2
Norovirus (Caliciviruses Norwalk-like virus)	0.6–77	0.5–3.5	0.1–6.8% of GI cases, 0.2% of asymptomatic controls	2–>14	<2 weeks
Rotavirus	0.5–6	4–8	0.2–0.3% of GI cases, 0.0% of asymptomatic controls (up to 83% of child diarrheal cases)	≤2 weeks	0.7–48
Cryptosporidium spp.	2–22	Weeks–months	0.4–13.% of GI cases, 0.0% of asymptomatic controls (higher for immunodeficient persons)	≤2 months	0.1–71%, 15–99% with past infections
Cyclospora cayetanensis	1–14	Weeks–months	0.0–6.1%		0.0–94
Entamoeba histolytica	2–3 days to 4 weeks	Weeks– months	0.0–7.4%	Years	0.0–43.7
Giardia lamblia/ intestinalis	1–3 weeks	Days–months/years	0.4–3.8% of GI cases 0.3–0.5% of asymptomatic controls (up to 33.3% of children)	5–41	1.6–% 37%

[a]GI = gastroenteritis.
[b]STEC = Shiga toxin-producing *Escherichia coli*.
[c]VTEC = verotoxin-producing *Escherichia coli*.

Incubation Periods

For ill persons, these can range from a few hours, e.g., *S. aureus* enterotoxin, to many weeks, e.g., HAV and *S.* Typhi. The longer the incubation period, the more opportunities there are that an infected person will excrete the pathogen. This is equally important for worker's contact persons, mostly likely the family or fellow workers, who may be the persons initially infected and excreting. The duration of illnesses is important too. Gastroenteritis symptoms may last many days or even weeks or months, e.g., chronic diarrhea, as in cases of infection with *Salmonella* Typhi, *Shigella* spp., HAV, and the protozoan parasites. Because employees want to return to work quickly after illness, and they do not usually receive paid sick leave, they may work while continuing to be ill or only having mild symptoms like occasional diarrhea, without reporting their conditions to management. Postsymptomatic long-term shedding can also occur with *Campylobacter, Salmonella, Shigella, V. cholerae, Yersinia*, enteric viruses, and parasites. Characteristics of foodborne pathogens transmitted by infected food workers with incubation period, duration of illness, carriage rate, and asymptomatic shedding are shown in Table 3.

Pathogen Survival

The soil matrix, relative humidity, and temperature all influence pathogen survival. Declines can be rapid on hands, but most pathogens that cause foodborne illness survive long enough on hands and contact surfaces to allow some transfer to food or fellow workers during a shift. *Salmonella* can survive for several hours on fingertips if they are not washed. Nonenveloped viruses such as norovirus, rhinovirus, and enterovirus are more stable on skin than are viruses with envelopes, such as the influenza virus.

All this information indicates that the risk of workers hands becoming contaminated and transferring them to food or food contact surfaces may not be unusual, and it is incumbent on these workers and their managers to develop good hygienic practices and continually monitor them during food production and preparation. Survival of pathogens and other enteric microorganisms on finger tip skin and different food contact surfaces is shown in Table 4.

Personal Hygiene and Employee Health

Barriers to Contamination

Barriers to contamination of food by food workers include glove use, and hand hygiene and its compliance, which have been reviewed by Todd et al. (2010a–e). Hands can carry billions of enteric bacteria or viruses (up to 10^9), especially if the individual is ill, caring for a sick person, changing diaper, or handling raw foods of animal origin. Thus, multiple barriers to limit transfer of pathogens to foods are essential. There are both physical and chemical barriers. Physical barriers include the use of properly engineered building walls and doors to minimize the flow of outside dust particles, microorganisms, and pests to food storage and food preparation areas; food shields (sneeze guards) to prevent aerosol contamination of displayed food by customers and workers; work clothing designated strictly for work, because clothing worn outdoors can carry undesirable microorganisms, including pathogens from infected family members, into the work environment; and utensils, such as spoons, tongs, and deli papers, (thin papers for grasping and weighing deli meats and serving bakery items) to prevent direct contact of hands and the food being prepared or served. Handling money and RTE foods should be two separate operations, preferably carried out by two workers. Chemical barriers include sanitizing solutions used to remove microorganisms, including pathogens, from objects or material used during food production and preparation; and laundering of uniforms, work clothes, and soiled linens. However, laundering, as normally practiced, may not effectively eliminate viral pathogens.

Glove Use is Another Well-Established Barrier

To prevent direct bare hand contact with food and food surfaces, many jurisdictions have made glove use compulsory for food production and preparation; if properly used, gloves can substantially reduce opportunities for food contamination. However, gloves have limitations and may become a source of contamination if they are punctured or improperly used. Experiments conducted in clinical and dental settings have demonstrated occasional pinhole leaks in gloves, and observations after many hours of the same glove use have shown that sufficient damage can occur to pose a risk for contamination of patients by the user. Wearing jewelry, rings, and artificial nails are discouraged, because these can puncture gloves and allow accumulation of microbial populations under them. Although such loss of glove integrity can lead to contamination of foods and surfaces in the food industry, improper use of gloves is more likely to lead to food contamination and outbreaks than leakage. Examples of these are not using gloves for all the required food handling operations, not washing gloved hands as frequently as desired, or allowing accumulated perspiration from the hands (through occlusion trapping of moisture with low oxygen levels, causing skin maceration) to contact food on removal of the gloves. Occlusion, trapping of moisture by the glove on the skin, during long-term glove use in food operations creates the warm moist conditions necessary for microbial proliferation and can increase pathogen transfer onto foods either through leaks and exposed skin or during glove removal. Most importantly, glove use can create a false sense of security resulting in more high-risk behavior that can lead to crosscontamination, especially if employees are not adequately trained.

Exclusions

Some jurisdictions have guidelines for employees working with food. These include being clean with trimmed fingernails, no artificial nails or nail polish, no jewelry, having short hair, and wearing clean uniforms or overalls. Employees are not allowed to work with boils or infected wounds or cuts, but may do so if they have an impermeable cover and a single-use glove over the impermeable cover. The most important set of conditions, but most difficult to supervise, is for an employee

Table 4 Survival of pathogens and other enteric microorganisms on skin and food contact surfaces

Infective agent	*Surfaces*	*Suspending media*	*Log or percentage loss*
Campylobacter	Glass slides and moist cloths	Room temperature	Decimal reduction times: glass, 0.5–24 h
	Poultry		Decimal reduction times: raw and cooked meats at 4 °C, ≥3 days
C. jejuni	Hands	Peptone water with chicken broth and 50% blood	3–7 log loss in 2–45 min
	Dry inanimate surfaces		Up to 6 days
E. coli	Fingertips	Broth, saline, milk	>90% after 5 min >99.9% after 1 h
	Coins, Teflon, glass	Broth	Survived 7, 9, and 11 days on the surfaces of pennies, nickels, and dimes/quarters, respectively; Teflon/glass for 4–7 days
Klebsiella aerogenes	Skin/fingertips	Broth, Ringer's solution	99% loss after 5–10 min
	Contaminated donor fabrics to hands	Broth	0.29% transferred and 66% loss on skin after 5 min
Listeria spp	Dry inanimate surfaces		1 day to months
Listeria monocytogenes	Fingertips	Broth, saline, milk	Loss: 0.45–99% after 15–45 min
Salmonella Typhi	Dry inanimate surfaces		6 h–4 weeks
Salmonella (nontyphoidal)	Dry inanimate surfaces		1 day–years
	Currency notes in Myanmar		*Salmonella*, enterotoxigenic *E. coli*, and *Vibrio* isolated from notes from butchers and fishmongers
	Coins		Survived 1, 2, 4, and 9 days on the surfaces of pennies, nickels, quarters, and dimes, respectively
	Fingertips	Broth	Still present 3 h later
	Formica™ surface, utensils, Teflon, glass	Egg white and yoke	Survived up to 17 days
	Dishcloths	Egg or blood	Survived >1 year
Shigella spp.	Dry inanimate surfaces		2 days–5 months
S. aureus	Glass	Broth diluted with distilled water at room temperature	29–89% loss after 12 h
	Skin of volunteers	Broth diluted with distilled water at room temperature	7–94% loss after 5–12 h
	Fingertips	Broth	99–99.99% loss after 5–90 min
	Dust exposed to different light intensities	Naturally contaminated sweepings from hospital wards	Up to 0.6 log in low daylight, 2 log in sunshine, 0.13–0.64 log in artificial light after 10 days
	Glass cover slip	Serum, water	0.0–95% loss after 100 min, up to 99% loss after 2–3 days
	Dry inanimate surfaces		7 days–7 months
S. pyogenes	Dust exposed to different daylight intensities	Naturally contaminated sweepings from hospital wards	Up to 0.5 loss in low daylight, 1.0 log loss in sunshine after 10 days
	Glass cover slip	Serum, water	0.0–91.6% loss in 100 min, 0.0–99% loss in 2–3 days
	Contaminated donor fabrics to hands	Broth	0.01–0.02% transferred and 38–77% loss on skin after 5 min
	Dry inanimate surfaces		3 days–6.5 months

(*Continued*)

Table 4 Continued

Infective agent	*Surfaces*	*Suspending media*	*Log or percentage loss*
V. cholerae	Dry inanimate surfaces		1–7 days
Hepatitis A virus	Fingertips	Fecal suspension	70–84% loss in 4 h
	Hands	Fecal suspension	50% loss in 5.5–7.7 h
	Stainless steel, copper Polythene, PVC, ceramic tile	Phosphate buffered saline	0.6–3 log reduction after 8 h at 20 °C (survival lowest on copper),
	Stainless steel	Fecal suspension	50% loss in 51–187 min at 20 °C
	Cloth	Phosphate buffered saline, 20% feces, drying for 3–5 h	0.8–1.6 log reduction
	Dry inanimate surfaces		2 h–60 days
Rotavirus	Fingertips	10% fecal suspension	43%, 57%, and 93% loss after 20, 60, and 260 min, respectively
	Aluminum, ceramic tile cloth	Phosphate buffered saline, 20% feces, drying for 3–5 h	0.3–1.2 log reductions
	Dry inanimate surfaces		6–60 days
Norovirus and feline calicivirus	Office surfaces	Feline calicivirus in culture medium with fetal bovine serum	90% loss after 0–4 h on computer keys, mouse, brass, and telephone wire; after 4–8 h on telephone receiver; after 12–24 h on telephone buttons, nondetectable at 72 h
	Metal disk	Feline calicivirus 10% fecal suspension	89% loss after 30 min, still detectable at 7 days
	Ham, lettuce, strawberries	Feline calicivirus 10% fecal suspension	57–99% loss after 30 min, still detectable in ham and lettuce after 7 days, and in strawberries after 5 days
	Dry inanimate surfaces	Norovirus (20% fecal solution) and feline calicivirus (cell lysates)	8 h–7 days
E. histolytica	Nail region of hands	Fecal suspension	Survival up to 45 min
	Fingers and thumbs	Fecal suspension	$\geq$95% in 10 min

not to have any communicable disease (as determined by gastrointestinal symptoms, and if necessary stool testing). If an employee has such a condition, the person must be excused from work until completely well, which may depend on the working conditions (e.g., 24 or 72 h after symptoms are absent or 7 days after being jaundiced, or with a medical form proclaiming them free from infection).Those working with food for highly vulnerable populations will require stricter control. Unfortunately, routine stool examinations have limited value for exclusion purposes. Asymptomatic-food workers may excrete pathogens without any indication of their health status, and tests rarely detect positive workers; for instance 1.6% of 307 954 workers in military food-service operations in Turkey were positive for enteric pathogens in stool specimens, based on tests mostly carried out on routine periodic examinations. Therefore, an in-depth knowledge of the behavior of workers by supervisors and careful monitoring of employees,for example, frequent visits to the toilet are important to minimize the risk of pathogen transmission.

Hand Hygiene

Personal hygiene, including showering and wearing hair nets, is a necessary component of performing safe food preparation and handling operations. However, many foodborne outbreak investigations have identified the hands of food workers as the source of pathogens in the implicated food. During various daily activities at home and work, hands can quickly become contaminated. Some of these activities increase the risk of finger contamination by pathogens more than others, such as the use of toilet paper to clean up following a diarrheal episode, changing the diaper of a sick infant, blowing a nose, or touching raw food materials. The most convenient and efficient way of removing pathogens from hands is through handwashing. Important components of handwashing include potable water for rinsing, and soaps to loosen microbes from the skin, followed by drying. Handwashing should occur after any activity that soils hands and certainly before preparing, serving, or eating food. Antimicrobial soaps are only marginally more effective than plain soaps at any one wash, but constant use with these soaps results in a build-up of the antimicrobial compound on the skin. The time taken to wash hands and the degree of friction generated during lathering are more important elements for removing soil and microorganisms than water temperature. However, excessive washing and scrubbing can cause skin damage and infections. Drying hands with a towel removes pathogens first by friction during rubbing with the drying material, and then by wicking away the moisture into that material. Paper rather than cloth towels should be encouraged, although single-use cloth towels are present in the washrooms of higher class hotels and restaurants. Warm-air dryers remove moisture from hands by evaporation and any surface microorganisms loosened by washing and vigorously rubbing the hands together; however, these take too long for efficient use. The newer high-speed air blades can achieve dryness in 10–15 s without hand rubbing. An effective handwash should remove most transient and some resident microorganisms and is typically facilitated by the use of soaps, detergents, and antimicrobial compounds. However, hands are never sterile and can become recontaminated if they come into contact with a contaminated surface or infected person as soon as the washing process is over. The overall efficacy of hand hygiene depends on many factors, including soil types, antimicrobial soap strength, or alcohol gel composition. In the food industry, alcohol-based antiseptics should be combined with regular washing of hands and should not replace handwashing and drying, or use of fingernail brushes. Wipes containing alcohol and antimicrobial compounds, as well as moisturizers, wetting compounds, etc., are widely used by the public. These have been shown to be more effective than plain soap and water, and should be considered as a feasible, practical hand hygiene intervention for remote food-service situations or where water availability is limited. Unfortunately compliance for handwashing in health care settings, food operations, and in the general society is not good, and a targeted management plan for hand sanitation in specific food operations needs to be developed and enforced as a part of the corporate culture of the company.

FOOD SAFETY ASSURANCE SYSTEMS

Cleaning and Disinfection

V Kakurinov, Consulting and Training Centre KEY, Skopje, Republic of Macedonia

Glossary

Cleaning The complete removal of food soil using appropriate detergent, physical methods, and chemicals under recommended conditions.

Disinfection Reduction, by means of chemical agents and/or physical methods, of the number of microorganisms in the environment to a level that does not compromise food safety or suitability.

Food hygiene These are measures and conditions necessary to control hazards and to ensure fitness for human consumption of a foodstuff, taking into account its intended use.

Sanitation It is cleaning and disinfection.

Sanitation program The planned way of practicing sanitation.

Soil Any material in an incorrect location.

Introduction

Cleaning and disinfection, or more precisely sanitation, is multidisciplinary applied science. Multidisciplinary because it incorporates knowledge from many sciences like: microbiology, chemistry, physics, mechanics, etc. Applied because it is the first and the most important line of defense of human health and it is related to environmental factors that are affecting health. Its principal goal is to combine design principles, development, implementation, modification, maintenance, restoration, and improvement of hygienic conditions and practices. As applied science, sanitation is directly connected with biological, chemical, and physical hazards control in food production chain and represents one of the most important tools for assuring safe and quality food products.

Sanitation usually refers to hygienic practices and procedures which are designed to create and maintain clean environment for food production, processing, preparation, storage, and distribution. However, sanitation is much more than cleanliness. Properly done sanitation is improving food products' quality, economics, shelf life, and esthetics. Also, sanitation is improving waste disposal, which is beneficial for the environment.

Speaking of cleaning, there are two types of processes:

1. Wet cleaning and
2. Dry cleaning

Wet Cleaning

Wet cleaning is a cleaning in which water is used. When speaking about the food industry, all food areas and food support areas has to be wet cleaned, except where dry cleaning is otherwise permitted. Increasingly, it is recognized that inappropriate use of water for cleaning in dry product food process environments can increase food safety risk by creating microbiological growth conditions. However, in many countries, government inspectors do not recognize a 'flush' or dry cleaning as providing a sufficient clean break in a production cycle. So wet cleaning usually needs to occur at intervals.

Generally speaking, cleaning and disinfection can be performed in five different stages:

1. Wetting and penetration of cleaning solution in the present soil and cleaned surface.
2. Reaction between cleaning solution with present soil and cleaned surface and facilitation of fats saponification, protein peptidization, and minerals dissolution, and displacement of solid and liquid soils from the cleaned surfaces.
3. Preventing redeposition of dispersed soils onto cleaned surfaces by provision of good rinsing properties.
4. Wetting cleaned surfaces with disinfection solution and its reaction or penetration with/into present microbial cells and completion of microbiostatic or microbicidal action.
5. In some cases (where disinfectant should be rinsed), dispersion of microorganisms from disinfected surface.

Fundamentals

Wet cleaning and disinfection are primarily affected by three factors: soil, surfaces type, and water.

Soil

As stated in the definition, soil is any material in an incorrect location. Examples are: organic deposits inside processing equipment, lubricants on conveyer belts, dust on equipment, etc.

Soil Nature

Soil nature will determine cleaning method, cleaning compound composition, and its concentration. That is why it is very important that personnel involved in cleaning process have a deep knowledge of the nature of the soil to be removed. Food production soils result from food product ingredients and composition and food production process. Regardless of used cleaning and disinfection method, increased mortality among microorganisms is achieved when soil is completely removed from the working surface.

More details about the organic (sugars, fats, and proteins) and inorganic soil (mineral substances) in terms of their solubility, degree of removal, and problems connected with heating are given in Table 1.

However, besides soil with pure composition (only sugars, proteins, etc.), it is very common to find complex soils or films which are combinations of food components, dust, oil, cleaner components, and/or hard water salts. These films solubility properties will depend on combination of different factors such as age, heat, dryness, time, etc.

Table 1 Characteristics of organic and inorganic pollutants

Substance	*Solubility*	*Removal*	*Problems iduced by heating*
Sugars	Soluble	Easy	Caramelization Hard for cleaning
Fats	Insoluble in water Soluble in bases	Partly hard	Polimerization Hard for cleaning
Proteins	Insoluble in water Soluble in bases and partialy in acids	Very hard	Denaturation Very hard for cleaning
Minerals	Solubility in water varies Soluble in bases	Easy and hard	Generaly not significant

Figure 1 Surface roughness tester.

Soil Quantity

The other important factor affecting cleanability is soil quantity. The most important factors affecting soil buildup are improper hygienic design and cleaning practices. That is why in order to remove soluble soil, it is very important to rinse food contact surfaces before cleaning. Also, heavy deposits require more mechanical energy and detergent to be removed.

Surfaces Type

Surface materials have very big influence on cleaning compound selection and cleaning effectiveness evaluation. Surface characteristics are:

- *Surface composition*: Food industry equipment contact surfaces are constructed from many different materials as: plastics, rubber, metal, marble, wood, etc. Most preferred surfaces are constructed metal or more specific – stainless steel. For highly corrosive products, high corrosion metal such as titanium is often used.
- *Surface finish*: Equipment product contact surfaces should have a finish of an acceptable roughness. According to European Hygienic Engineering and Design Group Doc. 8, large areas of product contact surface should have a surface finish of 0.8-μm Ra, or better. Surface finish can be determined by surface roughness tester (Figure 1) or surface roughness comparator (Figure 2).
- *Surface condition*: Product contact surfaces must be free of imperfections such as crevices, pits, racks, corrosion, etc. These kinds of surfaces are very difficult for cleaning and disinfection. To avoid this kind of defects, personnel responsible for cleaning should be educated and trained how to use and handle surface materials.

Water

Water is the most common solvent for cleaning and disinfection agents and is used both for start and final rinsing. It is a basic ingredient of all wet cleaning systems. Water is considered as an active ingredient that adds to the detergency of cleaners. It performs several very important functions such as being solvent of ionic compounds (salts and sugars) and

Figure 2 Surface roughness comparator.

fats (if used temperature is above its melting point) and can even be abrasive agent (if high pressure cleaning is used). Also, water aids in the suspension and antiredeposition of soils. Once the soil has been dissolved and emulsified away from the surface, water keeps the soil suspended away from the clean surface so that it can be carried away easily during the rinsing process. It is clear that without water, cleaning formulas would be much less effective.

Therefore, microbiological and chemical quality of water is very important. In principle, water used for cleaning should have drinking water quality. Ideally, food processing establishments should use pure water, but there is no ideal water supply. Therefore, cleaning compounds used have to be customized for the individual water supply and type of operation.

Water impurities have adverse effects on cleaning. For example, soluble manganese and iron salts concentrations more than 0.3 ppm will result in appearance of colored deposits on working surfaces.

Besides water's purity and potable quality, it is very important to know the hardness of water. Hard water contains large amounts of calcium and magnesium salts. If hard water is heated, the result will be sedimentation of calcium and magnesium salts. This property is also common for some cleaning agents, especially for basic ones.

Moreover, hard water is reduces detergents effects and creates scale. Besides unpleasant appearance, scale is unwanted because it:

- Harbors microorganisms (contains and protects them);
- Reduces transfer of heat energy, this can result in insufficient cooking, pasteurization, or sterilization; and
- Stimulates corrosion.

Scale formation can be reduced with addition of chelating or sequestering agents, which bind calcium and magnesium in insoluble complex. However, water softening is highly recommended because soft water is ideal for general food plant cleaning in terms of savings and effectiveness. This can be done with ion exchangers, which are replacing calcium and magnesium with sodium ions and thus forming soluble salts. Latest, and also the most expensive, water softening method is reverse osmosis. However, in some food processing such as canning of certain vegetables, a degree of hardness is often preferable.

One of the important water properties for cleaning and disinfection is its pH. Usually, pH of water ranges from pH 5 to 8.5 and there are no serious consequences to most detergents and sanitizers. However, if water is highly alkaline or highly acidic, addition of buffering agents is required.

Cleaning

The primary function of cleaning is to remove the food deposits, microorganisms, foreign bodies, etc. Under normal conditions, however, the removal of microorganisms and spores is not complete and that is why the cleaning has to be followed by disinfection.

In the preparatory phase, the production facility is cleaned from all residues, spillings, etc. Machines, conveyers, etc. are dismantled in a way which allows exposure of everything that is likely to collect microorganisms. Electric installation and all other sensitive systems should be covered and protected from contact with water and/or chemicals. At the start of the cleaning, pouring of water on the floor and machines should be avoided (nevertheless, whether it is pressurized water from a hose or water from water containers) before all food products are removed.

Before using cleaning chemical, all food and other types of residues should be removed by brushing, rubbing, etc., and then all the surfaces should be washed with water. Use of cold water is recommended because hot one can caramelize sugars and coagulate proteins and can create invisible film which does not allow full cleaning and represents potential niche of microorganisms and produces unpleasant odors.

After this, process of cleaning should be inspected and cleaning should be recorded.

Cleaning Agents

Efficient cleaning can be performed only if appropriate detergents or cleaning agents are used. The ideal detergent should:

- Possess enough chemical energy to dissolve the material to be removed.
- Possess small surface tension which allows penetration in all crevices and indentations. It should break down waste materials and maintain them in a state of suspension.
- Be capable to perform water softening, which prevents scale formation, if used with hard water.
- Be rinsed freely from the facility.
- Leave no chemical residue on the equipment.
- Cause no corrosion and other harmful effects in the facility.
- Be not hazardous for people.
- Be appropriate for the specified cleaning procedures.
- Be easily dissolved in water, and their concentration should be easily checked, if they are in solid state.
- Be in accordance with existing legal requirements regarding safety and environment.

All cleaning methods including foam and submersion require adequate contact time.

It has to be said that there is no detergent with all listed features. Therefore, for different types of equipment and production, detergent that contains most of the above mentioned properties or their combinations, which will serve best for their intended purpose, should be used. A cleaning solution or detergent is blend composed from a number of components or more precisely, from water as a solvent with:

- Surfactants,
- Alkaline agents,
- Acid agents, and
- Chelating (sequestering) agents.

Surfactants are usually organic compounds with amphipolar nature, i.e., they are composed of both hydrophobic or lyophilic (nonpolar) tail and hydrophilic or lyophobic head. According to the composition of their head, they are classified as: nonionic (no charge groups in its head), anionic (negative

charge), cationic (positive charge), and zwitterionic (a head with two oppositely charged groups). Most common surfactants are anionic and nonionics. Surfactant's amphipolar nature facilitates cleaning by reducing surface tension and fat's emulsification. When surfactant is added on the water surface, its polar heads disrupt water's hydrogen bonds, which lead to reducing water surface tension and allow water droplets to collapse and wet the cleaning surface. This so-called 'wettability' enhances penetration in present soil and surface, regardless its irregularities. When surfactant is added in water/fat emulsion, its hydrophilic heads are dissolved into water and hydrophobic ends are dissolved in the fat, causing fats/oils emulsification. In the case when fat is bound to a surface, the forces which act on water/fat interface force fat particle to take form of a sphere, which leads to fat detachment from the cleaning surface.

Alkaline agents are cheap cleaning agents. Generally, they can be divided into two groups: highly alkaline and moderate detergents. Highly alkaline detergents are caustic soda (NaOH) or caustic potash (KOH). Very important property of these detergents is that they saponify fats (forming soap) and break down proteins. They are used in many clean in-place (CIP) systems or bottle-washing applications. However, they are highly corrosive and hazardous for operators. Moderately alkaline detergents are less effective than highly alkaline detergents. They include sodium, potassium, or ammonium salts of carbonates, silicates, or phosphates. One of the most effective is trisodium phosphate. Silicates are most often used as a corrosion inhibitor. The main disadvantages of alkalis are their tendency to precipitate hard water ions, formation of scum's with soaps, and poor rinsability.

Acid's major functions are control of mineral deposits and water softening. When speaking about deposits, acids are very useful in dissolving carbonate and mineral scales, hard water salts, and proteinaceous deposits. They are more effective when they are more concentrated, but this means that they will be more corrosive. Acids are not used very frequently; they are used more for periodic cleaning.

Chelating (sequestering) agents' primary function is control of water hardness. They are usually added to surfactant ions as aid to their capacity for dispersion and rinsability. In fact, they are used to prevent precipitation of mineral ions by forming soluble complexes with them. Some common chelating agents used in industrial cleaning compounds include ethylene diamine tetra acetate (EDTA), sodium citrate, and zeolite compounds. Most widely chelating base is EDTA. The only drawback is that this substance is expensive. There are cheaper alternatives but most of them are phosphate based, which are banned because of their adverse effect on environment.

Cleaning Efficiency

Cleaning procedure efficiency mainly depends on:

- Type and amount of waste to be removed;
- Chemical and physicochemical properties of the cleaning agents (strength, surface activity, etc.) and their concentration and temperature used during application;
- Applied mechanical energy (less or more brushing, higher or lower water pressure, etc.);
- Condition of the cleaned surfaces (new/old, damaged/not damaged);
- Type and condition of surfaces. Some surfaces are very difficult to (e.g., corroded steel or galvanized aluminum) to clean, , which means that disinfection will be ineffective. The same applies for other surfaces such as wood, rubber, etc.;
- Residues which are usually removed from working surfaces. Usually they are organic substances such as sugars, fats, and proteins. These matters are most efficiently cleaned with strong base detergents (especially caustic soda, NaOH);
- Types of inorganic substances such as calcium salts, etc. Best agent for removal of these substances are acids; and
- Presence of biofilms, created by bacteria, fungi, yeasts, and algae (removal agents same as for organic substances).

Disinfection

Traditionally, the terms 'disinfection' and 'disinfectants' are used for description of procedures and means in the food industry to achieve acceptable standard of hygiene from microbiological point of view. It has to be said that these procedures and materials cannot ensure 'sterility' – complete absence or elimination of microorganisms in a given environment.

Disinfection Agents

Ideal disinfectant should have the capacity to:

- Possess antimicrobial effect to kill all microorganisms present in a given environment;
- Have sufficient surface tension that allows better penetration in material pits and pores;
- Be rinsed freely, should flow out of the facility, and should not cause any kind of pollution (products or environment);
- Promote creation of resistant strains of microorganisms or microorganisms which can survive its action;
- Not cause corrosion or other type of damages in the facility. It is recommended to consult equipment manufacturers and disinfectant suppliers.;
- Not discolorate food or other materials;
- Not be hazardous to employees;
- Be compatible with disinfection procedures that are used in building;
- Be easily dissolved in water and their concentration should easily be determined, if in solid state;
- Be stored for extended period of time;
- Be in compliance with legal requirements regarding safety, environment, and biodegradability; and
- Be reasonably economical. When it comes to economics, disinfectant concentration should always be considered. Food producers often purchase cheaper packaging of disinfectant, not taking into account the required concentration (because ready to use solution is normally cheaper than concentrate), how long is the period of use of a single package, and how many packages are needed monthly or yearly.

There are number of disinfection techniques such as steam (water at elevated temperature, widely used in aseptic food production), hot water (immersion of small equipment, parts, utensils, and containers into water heated to 80 °C or higher – sterilization), irradiation (radiation at a wavelength of 2500 Å in the form of ultraviolet light or high-energy cathode or γ-rays), ozone (use of O_3 as oxidizing agent), dry cleaning (mechanical removal of soils by sweeping, brushing, wiping, and vacuuming), and chemical disinfection (different chemicals with disinfection effects). Chemical disinfection and steam/hot water disinfection are most popular. Usual chemicals used for disinfection are listed in **Table 2**.

Table 2 Types of disinfectants

Disinfectants types	*Forms/description*	*Advantages*	*Disadvantages*
Chlorine	Hypochlorite's gas form organic chlorine (e.g., chloramines)	1. Kills many types of microorganisms 2. Do not create film on surfaces 3. Relatively cheap 4. Easy to determine the concentrations	1. May cause metal corrosion and rubber weakening 2. Irritates skin, eyes, and throat 3. Unstable and readily decomposable 4. Liquid chlorine loses its efficiency during storage 5. Reduced activity in hard water 6. Sensitive to pH 7. Leads to food discoloration 8. Oxidize fats
Iodophores	Iodine dissolved in surfactant and acid	1. Kills many types of microorganisms 2. Organic matter has low influence on their efficiency 3. Less sensitive to pH than chlorine types disinfectants 4. Solution color indicates disinfectant activity 5. Easy to determine the concentrations	1. May color plastic and porous materials 2. Inactivated more than 50 °C 3. Reduced activity at alkaline pH 4. More explosive than hypochlorites 5. May be inadequate for clean in-place (CIP) (foam creation)
Quaternary ammonia compounds	Benzalkonium chloride and related compounds, sometimes named as quats or qaqs (QAQs)	1. Efficient against *Listeria monocytogenes* 2. Have residual antimicrobial activity if not rinsed 3. Organic matter have low influence on their efficiency 4. Can be used in form of foam 5. They are not corrosive 6. Efficient in odor control 7. Easy to determine the concentrations	1. Inactivated by most of the detergents 2. May not be efficient against some microorganisms 3. May be inactivated by hard water 4. Efficiency depends on the formulation 5. Not efficient like others on low temperatures 6. May be inadequate for CIP (foam creation)
Acid – anionic compounds	Combination of some surfactants and acids	1. Performs sanitation and acid rinsing in one step 2. Hard water slightly reduces their efficiency 3. Very stable 4. Organic matter have low influence on their efficiency 5. Can be applied at high temperatures	1. May cause corrosion of some metals 2. Their efficiency depends on type of present microorganisms 3. Sensitive to pH (applications below pH 3.0) 4. More explosive than others 5. May be inadequate for CIP (foam creation)
Peroxy compounds	Acetic acid and hydrogen peroxide combined to create peroxyacetic acid	1. Kills many types of microorganisms 2. Best against bacteria's in biofilms 3. Efficient at low temperatures 4. Relatively stable 5. Complies with regulations for direct removal in water supply networks 6. Low foaming (appropriate for CIP)	1. May cause corrosion of some metals 2. Inactivated by some microorganisms and organic matter 3. Low efficiency against yeasts and molds 4. More explosive than others
Carboxilic acids	Fatty acids combined with other acids	1. Kills many types of microorganisms 2. Hard water slightly reduces their efficiency 3. Performs sanitation and acid rinsing in one step 4. Stable in the presence of organic matter 5. Low foaming (appropriate for CIP)	1. May damage common steel 2. Inactivated by some detergents 3. Sensitive to pH (applications below pH 3.5) 4. At low temperatures less efficient than chlorine disinfectants 5. Low efficiency against yeasts and molds

(*Continued*)

Table 2 Continued

Disinfectants types	*Forms/description*	*Advantages*	*Disadvantages*
Chlorine dioxide	Gas diluted in solvent or with acidification of chlorites and chlorate salts	1. Kills many types of microorganisms 2. Less sensitive at pH 3. Organic matter have low influence on their efficiency 4. Stronger oxidizing agent than chlorine 5. Less corosive than chlorine	1. Not stable and can not be stored 2. Potentially explosive and toxic 3. Relatively expensive
Ozone	Gas diltued in solvent	1. Kills many types of microorganisms 2. Stronger oxidizing agent than chlorine and chlorine dioxide	1. May cause metal corrosion and rubber weakening 2. Potentialy toxic 3. Inactivated by organic matter (similar as chlorine) 4. Not stable and can not be stored
Hot water and heated solutions	Water at 78–88 °C	1. Kills many types of microorganisms 2. Penetrates in irregular surfaces 3. Relatively cheap 4. Appropriate for CIP	1. May form film or scale 2. May cause burning (of employees) 3. Efficiency depends from contact time

Following are the most used disinfectants:

Chlorine

This is the most frequently used and the most common disinfectant. Chorine is available in several forms, for example, sodium hypochlorite solutions, chloramines, etc. and can also be used in the gaseous forms (e.g., chlorine dioxide).

Chlorine disinfectants at a concentration of 200 ppm free chlorine are very active. These solvents at room temperature (23–28 °C) do not corrode high quality stainless steel but can be corrosive for less resistant materials. If organic materials are present, then its disinfection effect declines rapidly. If the ingredients are dissolved in water, hypochlorite acid is formed and has a strong disinfection action expressed through oxidation. However, the solution is very unstable, especially if they are acidic solutions, because poisonous chlorine gas is created.

Unfortunately, chlorine's antimicrobial effect is stronger in acid than it is in alkaline solutions, which means that working pH should be chosen as a compromise between stability and efficiency.

Iodophores

These disinfectants contain iodine, which is bound to a carrier. Common iodophor solutions are formulated with phosphoric acid because that way the pH of these disinfectants is lowered from 2 to 4. This is because of the greatest effect of iodine in this pH range. Most effective concentration is 25 ppm free iodine.

Iodophores are disinfectants with broad antimicrobial spectrum. However, they are less effective against sporogenous bacteria and viruses. They are inactivated by organic matter.

Commercial solutions are often acidic. They can be corrosive, which depends mostly on their formulation. It should not be used at temperatures more than 45 °C because that leads to release of free iodine. If iodophores come in contact with caustic agent residue (mostly because of inappropriate rinsing and being in the dead zones), unpleasant smell is created (so-called phenol smell).

Hydrogen Peroxide and Peracetic Acid

These disinfectants have broad antimicrobial spectrum. Hydrogen peroxide readily kills sporogenous bacteria at high temperatures and peracetic acid act on bacteria and viruses within timeframe of 30 min, whereas they act on vegetative bacteria within 5 min.

Solutions can be used independently or in combination with other disinfectants. Usually they are used on previously cleaned surfaces because presence of organic matters lowers their efficiency rapidly. They should be used in concentrations of 200–300 ppm.

Quaternary Ammonia Compounds

These disinfectants are effective fungicides (killing fungi) and bactericides (killing bacteria). However, they are less effective toward Gram-negative bacteria. To avoid creation of resistant microbes, occasionally, quaternary ammonia compounds should be replaced with other disinfectants.

Their low surface tension allows them excellent penetration in different materials, but the drawback is that they are hard for rinsing. If they come in contact with the active anionic detergents, then it is possible that they will be inactivated and therefore subsequent use of these disinfectants should be avoided. For working surfaces, concentrations of 200 ppm should be used.

Disinfection Efficiency

There are number of factors that are affecting microbicidal effectiveness of chemical disinfectants. Most important are:

1. Concentration (minimal, which is required for effective disinfection).
2. pH (water pH and actual pH of resulting solution for optimal effect).
3. Temperature (warm = 36–45 °C, hot = 50–75 °C).
4. Exposure time (minimal time needed for complete disinfection).

Table 3 Commonly used concentrations of certain disinfectants

Disinfectant	*Working surfaces into contact with food (ppm)*	*Working surface without contact with food (ppm)*	*Water (ppm)*
Chlorine	100–200[a]	400	3–10
Iodine	25[a]	25	
Quat's	200[a]	400–800	
Chlorine dioxide	100–200[a,b]	100–200	1–3[b]
Peroxyacetic acid	200–315[a]	200–315	

[a]Higher concentrations of the specified range is the maximum concentration without rinsing (surfaces have to be dried).
[b]Includes a mixture of oxichlorine ingredients.
Source: Reproduced from Anonymous (2000) *Sanitation Control Procedures for Processing Fish and Fishery Products Manual*. Gainesville, FL: Florida Sea Grant College Program.

5. Equipment cleanliness (soil can affect disinfectant effect).
6. Water hardness (different disinfectants for different water hardness for optimal effect).
7. Incompatibility (disinfectants mostly are incompatible with each other and often with soaps or other additives).

In Table 3, generic concentrations for some disinfectants are shown.

Application of Cleaning and Disinfection Agents

Cleaning and disinfection can be performed with various methods. Usually, simple manual cleaning performed with simple tools is sufficient, but having in mind that there are more than few surfaces to be cleaned and disinfected, special equipment for providing mechanical energy and chemicals' dispersion is necessary. There are many methods and means of subjecting the surfaces to cleaning compounds and solutions. Depending on the economy and effectiveness, in general, following methods are used:

1. *Manual method:* This method is used for cleaning small items; chemical is applied and spread with brushes, sponges or cloths, scrubbers, etc. Positive aspects of this method are that a high degree of mechanical energy can be applied directly where it is needed, and if used with soak tanks (see below, Cleaning out of place (COP) system), contact time can be prolonged and chemical and temperature input can be increased. If larger areas are to be cleaned, only low levels of temperature and chemical energy can be applied in order to keep the operator safe. Main advantages of this method are: low-cost equipment is required; it is adaptable to all types and sizes of facilities, equipment, and tools; and it is affordable in small food-producing operations. However, this method is labor intensive and time consuming; its effectiveness depends on human factor; most of the time it is inconsistent; and there is greater opportunity for cross-contamination.
2. *Soaking:* Small equipment/fittings/valves are immersed in cleaning solutions in a small vessels or sinks, whereas larger vessels (tanks and vats) are partially filled with a cleaning solution. This solution should have high temperature (50–52 °C) and the equipment should be soaked for 20–30 min before being manually or mechanically scrubbed. One relatively recent approach is the ultrasonic cleaning tanks. In these tanks, equipment immersed in a cleaning solution is cleaned by the scrubbing action of microscopic bubbles produced by high frequency vibrations (20 000–40 000 cycles per s).
3. *Spray method:* This is the most used method in food industry. Using fixed or portable spraying units, cleaning solution is applied on equipment surfaces.
4. *CIP systems.* This automated cleaning system represents cleaning method where contact surfaces of vessels, equipment, and pipe work are cleaned in place, i.e., without dismantling. Primary energy source required for soil removal in this system is fluid turbulence in pipelines.
5. *COP system*. Most effective cleaning for small parts (e.g., pump rotors, hoses, tubing, piping, filter housings, needles, diaphragm valves, fittings, gasket, mixers, blenders, filler components, tools, bowls, belts, etc.) is in recirculating parts washer (called COP). These sanitary tanks are utilized in combination with a recirculating pump and distribution headers, which provide agitation of cleaning solution. Sometimes parts of this washer are serving as recirculating unit for CIP cleaning.
6. *Foaming:* This method uses concentrated blend of surfactants, which are added to highly concentrated alkaline or acid cleaner solutions. When applied with foam generator, this cleaner will have form of stable foam. This foam is clinging at surfaces. That way, contact time between liquid and soil is increased and rapid drying and liquid cleaner runoff is prevented.
7. *Gelling:* In this method, concentrated gelling agent is dissolved in hot water, which results in viscous gel formation. Afterward, appropriate cleaning agent is dissolved in the hot gel. Resulting gelled acid/alkaline detergent is sprayed on surface which is to be cleaned. Gelled cleaner forms thin film on the cleaned surface for 30 min or more and attacks present soil. At the end, soil and gel are rinsed with pressurized hot water.
8. *Fogging systems:* This method is used to create and disperse a disinfectant aerosol which reduces the number of airborne microorganisms (2–3 log in 30–60 min) and to apply disinfectant to difficult-to-reach surfaces, especially overhead surfaces. For surface disinfection, fogging will be effective only if sufficient amount of chemical is deposited onto the surface. Application of this method represents potential health risk (inhalation). To avoid this risk, at least 45–60 min are required for settling of disinfectant fog and reentering of operatives in production area.
9. *High- and low-pressure water jets:* This method can be used for application of different cleaners, especially foam cleaners and rinsing of cleaning chemicals. Main advantages of this method is fast application of cleaners on walls, floors, and stationary equipment and allowing easy reach to hard-to-clean areas. However, during application, there is a loss of water temperature. Also, low-pressure systems generally require higher water volumes and high pressure may cause cross-contamination with resulting aerosol's overspray (Figure 3).

Figure 3 Aerosols creation resulting from very high pressure.

10. *Abrasive cleaning:* Abrasive-type powders and pastes are still available and used for removing difficult soil. Complete rinsing is necessary and care should be taken to avoid scratching stainless steel surfaces. Scouring pads should not be used on food contact surfaces because small metal pieces from the pads may serve as focal points for corrosion or may be picked up in the food.

Sanitation equipment should be dedicated to tasks for which they are designed. They should optimize cleaning effectiveness and minimize risks from cross-contamination between different food-producing areas. For example, brushes should have proper stiffness and they should not be used simultaneously for floor scrubbing, application of cleaners' solution, and equipment cleaning.

Very important feature for sanitation equipment is their hygienic design. This equipment should be constructed from nonporous, nonoffensive, smooth, and easily cleanable materials. Crevices, pits, and gaps are not allowed because they are niches where microorganisms are collected, multiplied and spreading around. Most desirable construction material is not only the stainless steel but also mild steel or other corrosion subject materials can also be used, provided that they are suitably protected (painted, coated, etc.). Wood as a construction material should be avoided.

After their use, cleaning tools and equipment should be thoroughly cleaned and, if appropriate, disinfected and dried.

Pathogen Resistance to Disinfectants

As mentioned before in Section Cleaning, cleaning always antecede disinfection, because without proper cleaning, disinfection cannot fulfill its primary goal – inactivation and/or killing of microorganisms present. In practice, 90 ± 95% of the present microorganisms are removed by an efficient cleaning protocol. Following process of disinfection reduces the amount of remaining microorganisms to acceptable level.

When disinfectants are applied in optimal conditions such as concentration, pH, temperature, and time, susceptible microbial cells are killed. Generally speaking, disinfectants have broad spectrum of targets and mechanisms when attacking microbial cell. The most known are:

- Breaking down cell membrane and its outer layers, resulting in rapid cell death/inactivation of the microorganism.
- Damaging enzymes and important metabolic processes. Some heavy metals (e.g., silver, mercury, and copper) are poisonous to enzymes. If they are added as salts or organic mixtures, they bind to enzymes' SH groups, which results in changes in their tertiary and quaternary structure.
- Affecting proteins' synthesis, resulting in prohibition of growth.
- Inhibiting deoxyribonucleic acid (DNA) synthesis or DNA strands' breakage, resulting in the blockage of cell growth.

Just like every other living organisms, microorganisms are protecting themselves against all kinds of influence from the environment. When speaking about their response to disinfectant, they can generally respond with:

1. Alteration of target,
2. Reduction of target access,
3. Inactivation of disinfectant, and
4. Low or nonsensitivity to applied disinfectant.

As disinfectants have broad spectrum of action, it is very unlikely that their response will be alteration of the target. Possibilities are that they will protect themselves by one or the other mentioned responses or with combination of resistance mechanisms. This kind of microorganisms' resistance responses to disinfectants can be intrinsic (innate), apparent (pseudo-), or extrinsic (acquired).

Intrinsic (Innate) Resistance

Intrinsic resistance is resistance that is naturally present in the microorganism. It is a property controlled by chromosomes and is related to the general physiology of the microorganism.

Differences in resistance to antimicrobials occurring among different types, genera, species, and strains of microorganisms under identical environmental conditions and antimicrobial concentrations are most likely controlled innately.

Different types of microorganisms show different innate resistances to chemical biocides. This is indicator for relative activity of different levels of disinfection. Highest innate resistance are showing sporogenous bacteria (e.g., *Bacillus cereus* and *Clostridium perfringens*), followed by coccidia (e.g., *Cryptosporidium* sp.), mycobacteria (e.g., *Mycobacterium tuberculosis*), nonlipid or small viruses (e.g., poliovirus and coxsackievirus), fungi (e.g., *Aspergillus* sp. and *Candida* sp.), lipid or medium-sized viruses (e.g., herpes and human immunodeficiency virus), and vegetative bacteria (e.g., *Staphylococcus* sp. and *Pseudomonas* sp).

Mechanisms of intrinsic resistance in microorganisms to disinfectants vary. For example, some microorganisms have cellular barriers, which prevent entry or uptake of disinfectants (e.g., spore coat and cortex in sporogenous bacteria, waxy cell wall in mycobacteria, outer membrane of Gram-negative bacteria, and teichoic acids in Gram-positive bacteria), some of them possess cellular efflux (i.e., mechanisms that pump

compounds out of the cell), which reduces efficacy of a number of microbicides, including benzalkonium chloride and related compounds, phenolics parabens, and intercalating agents (*Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Escherichia coli*), or there is lack of a biochemical target for antimicrobial attachment or microbial inactivation, and some microbes have enzymes which inactivate microbicide applied.

Proven examples for intrinsic resistance to disinfectants are: bacterial spores and *Cryptosporidium* sp. having innate chlorine resistance, *Bacillus* sp. being intrinsically resistant to benzoates due to their ability to metabolize this compound, *P. aeruginosa* being resistant to many disinfectants, and *Coxiella burneti* surviving standard disinfectants.

Apparent (Pseudo) Resistance

Apparent resistance is term for resistance which occurs when microorganism appears as resistant to a certain kind of microbicide, but when the same microorganism is placed in a microbicide-free environment, the resistance disappears. This means that this kind of resistance is not stable and is considered as pseudo resistance.

There are two main reasons which are causing apparent resistance:

1. Presence of interacting stress conditions (e.g., low pH and polarity). The lower the pH of a food product, the greater the proportion of acid in an undissociated form, and the greater the antimicrobial activity. Another important factor that affects apparent activity is polarity. Polarity relates to the molecule ionization and the contribution of any hydrocarbon side groups or hydrophobic parent molecules. To attach and pass through the cell membrane, antimicrobials have to be soluble in the aqueous phase and lipophilic phase. Microorganisms exposed to food antimicrobials in lipid-containing food systems, due to the solubilization or binding of the antimicrobials by the lipids, demonstrates apparent increased resistance.
2. Conditions of the disinfection application. Incorrect application of disinfectant are as follows:
   - Application of disinfectant on surfaces with biofilm,
   - Use of an inappropriate disinfectant (i.e., disinfectant with limited spectrum of activity),
   - Incorrect disinfectant use (not according to the recommended conditions like concentration, contact time, and temperature), and
   - Insufficient availability of the reactive agent.

Obviously, these reasons easily can result with survival of microorganisms and although it is not considered as genuine microbial resistance, probably it is the most widespread form of perceived resistance.

Extrinsic (Acquired) Resistance

Extrinsic resistance is the result of the acquisition of new genetic information in the existing genome. This information can be plasmid or nonplasmid encoded.

Nonplasmid-encoded resistance usually occurrs when microorganism is exposed to gradually increasing concentrations of a certain microbicide. In most cases, plasmid-encoded resistance is a form of resistance against metal-based microbicides (silver, copper, or mercury). Nevertheless, it is shown that microorganisms may develop acquired resistance to chlorine. Conditions which are contributing to the development of resistance include application of sublethal concentrations of chlorine used in error or neutralization of the compound during use. Studies report that *Salmonella* show resistance against hypochlorous acid concentrations of up to 72 $\mu g\,ml^{-1}$. Development of resistance to other compounds commonly used as disinfectants in food processing environments is also possible.

Pickett and Murano exposed *Listeria monocytogenes* to sublethal concentrations of different disinfectants. Results showed that *L. monocytogenes* developed resistance to the minimal inhibitory concentration (MIC) of the acidic anionic disinfectant (500 $\mu g\,ml^{-1}$) when challenged after an initial shock of 350 $\mu g\,ml^{-1}$ with the same disinfectant. They suggested that preexposure of the cells to the dissociated form of the acid, but not to the undissociated form, caused *L. monocytogenes* to become resistant.

There are few authors who suggested that use of a single type of disinfectant may allow selection and persistence of resistant strains. For example, Lemaître *et al.*, showed that strains of *L. monocytogenes* isolated from poultry were shown to be resistant (MIC = 16 $\mu g\,ml^{-1}$) to the quaternary ammonium disinfectant – benzalkonium chloride. Resistance was plasmidborne and could be transferred to other microorganisms such as *Listeria* and *S. aureus*. The plasmid genes may code for an energy-dependent efflux system.

A number of authors suggest that there is a relationship between microbial resistance to disinfectants and microbial resistance to antibiotics that are used therapeutically. It is already reported that cross-resistance exists between microbicides and antibiotics, and antibiotic-resistant *S. aureus* and *Staphylococcus epidermidis* developed plasmid-mediated resistance to chlorhexidine and quaternary ammonium compounds. Also, methicillin-resistant *S. aureus* were significantly more resistant than methicillin-sensitive strains to both povidone-iodine and hypochlorite.

Microbial resistance to cleaning and disinfection agents and measurements are major consideration when developing sanitation plan and strategies. In that regard, users are always looking for cleaning and disinfection agents' concentration, contact time, and temperature, which eliminate most resistant types of microorganisms.

Sanitation

Sanitation is a sum of cleaning and disinfection. Sanitation is the appropriate treatment of the working surface that efficiently destroys all vegetative and some sporogenous microorganisms that can have adverse effect on human health or is reduces the number of other undesirable microorganisms, without any harm to consumers and safety of the product.

Different procedures are an integral part of the sanitation. Brief description of the subsequent processes or sanitation operations that are generally performed is following:

- Removing food product(s);
- Cleaning the surrounding, including waste beans;

- Dismantling the equipment and exposing the working surface to be cleaned;
- Removing and transferring the smaller equipment, parts, and connections in a separate facility intended for their cleaning;
- Covering sensitive installations and their protection from water;
- Cleaning the workspace, machines, and equipment from the food residues with jet of water and use of brushes, brooms, etc. (it can be cold and/or hot water. Recommendation is to first clean with cold water and brush, and then to apply hot water);
- Applying the cleaning agent and use of mechanical energy (e.g., pressure or rubbing);
- Rinsing the cleaning agent completely with water after recommended contact time, because the residues from this agent can inhibit the action of disinfectant;
- Cleaning control;
- Disinfecting with chemical disinfectant or hot water;
- Rinsing the chemical disinfectant completely with water after recommended contact time. (This is not necessary for some disinfectants which have very short time of decomposition, for example, hydrogen peroxide);
- Reassembling the equipment and leaving enough time for drying;
- Cleaning and disinfection control; and
- In some cases redisinfecting (e.g., with hot water or low concentration of chlorine) before starting the production.

Sanitation operations have to be carried out in a manner that does not contaminate food and/or packaging material during or after cleaning and disinfection (e.g., aerosols, chemical residues, etc.). Also, these operations have to be performed at room level, i.e., all environmental and equipment surfaces in one area should be cleaned at the same time.

It is essential for each food producer to have their own written sanitation program. Scope of this program should be premises, production, and storage areas. Within this program, special sanitation and housekeeping procedures required during production should be specified. This written sanitation program should at least include:

- Area/line which has to be cleaned; frequency; and responsible person;
- Specified special procedures for cleaning and disinfection that are performed during production (e.g., cleaning between shifts, with procedures, and responsible person);
- Special instructions for specific equipment cleaning and responsible person;
- Used cleaning equipment, together with instructions (e.g., pressure, volume, etc.);
- Disassembly and assembly instructions;
- Detergents/sanitation materials that are used. In the description, their generic names can be used and their solution factors, water temperature, etc. should be clearly stated;
- Mode in which chemicals are used (according to manufacturer's instructions);
- Methods of application, contact times, foam consistency, high/low pressure, etc.;
- Instructions for rinsing, water temperature, etc.;
- Instructions for sanitation, commercial and generic names, dissolving factors, time of action, etc.;
- Instructions for final rinsing (if appropriate); and
- Instructions for safe handling of hazardous products.

For each production section and piece of equipment in this written program, name of responsible person, used chemicals, procedures, and frequency of cleaning and disinfection should be specified.

This program should be documented and recorded. Records for monitoring corrective actions and verification should be available on demand.

Very important issue in sanitation programs is timing. Generally, when in production period, facilities should be cleaned and/or disinfected at least once a day, and equipment which is cleaned manually or out of place, at least once a day should be dissembled, cleaned, and monitored. CIP equipment should be dissembled and controlled according to CIP program. Also, there are periodical sanitations (weekly and monthly), which means that cleaning and disinfection should be performed thoroughly and beyond the level of sanitation on daily basis.

Methods of cleaning and sanitation program have to be monitored and verified (e.g., microbiological analysis, etc.) by authorized institutions and/or responsible person/laboratory.

Records for monitoring corrective actions and verification should be available on demand.

Assigned person is responsible for the sanitation program. This person has to possess deep technical hygiene knowledge. Scope of his/her job description includes: selection of sanitation chemicals, equipment and methodology, selection of a appropriate supplier of chemicals, ensuring that adequate supplies and cleaning materials are always available, internal training of sanitation operatives, development and implementation of cleaning schedules and monitoring system, and presentation of hygiene issues to senior management.

Monitoring Sanitation Programs

A prerequisite for effective disinfection is effective cleaning. This just shows how important the process of monitoring is. Most important control is sensory (visual, touch, and smell) inspection that show that all working surfaces:

- Are visibly clean;
- On touch and do not contain food residues, scale, or other material; and
- Do not have unpleasant odor.

However, although this method of assessing hygiene of cleaned surfaces enable detecting significant residues, small amounts (not visible) of soil and microorganisms' contamination cannot be revealed.

Besides visual check, there are few other cleaning parameters which can be monitored. If cleaning is performed with hot water, then concentrations, pH values, temperature, and contact time of the cleaning agent has to be monitored and recorded. Rinsed water pH value measuring (or similar tests) is used as a proof that the cleaning agent is completely removed (to avoid mixing with disinfection agent). These controls are rapid and are enabling decision making in the sense whether cleaning should be completely or partly repeated whole or in part or should be continued with

disinfection. All the above mentioned monitoring and control measures should be integral part of the factory sanitation program and quality system control. At this stage, there is no need for microbiological analysis because to date there are no really fast and precise methods.

Provided that cleaning control is appropriate, disinfection control should at least include the following parameters:

- Time and temperature control (if heat disinfection is used);
- Used chemical active concentrations control;
- Control whether all surfaces to be disinfected are covered with disinfectant; and
- Contact time control.

Common means of verification of sanitation program effectiveness and degree of cleanliness of equipment and foodstuffs are microbiological tests and controls. Selection of the most appropriate microbiological technique is based on desired accuracy and precision, desired results, and the amount of effort and expenses available. More techniques are available, but none of them is ideal and cannot derive rapid result.

Precise microbiological analysis takes between 24 and 72 h and sometimes 168 h (7 days). However, these analyses should be performed in predetermined periods of time and frequency and should include critical control points. Most used methods are:

Swabbing

This method employs use of sterile stick with sterile cotton (sometimes sponge) on one end. The part is swabbed on the disinfected working surface with the cotton and submerged in solvent which can be used for further dilutions. From the final dilution, usually 1 ml is poured on/into appropriate nutritive media and numbers of microbes are determined. Sterile swabs are convenient for taking samples from difficult-to-reach places such as corners, dead legs, valves, etc.).

Contact Plate Method

This method employs ready-to-use petri dishes or contact slides with different nutrient Media. They are applied on disinfected surface, cultivated, and then the number of microbes is determined. This technique is used for flat surfaces.

Membrane Filtration

Final rinsing water is passed through system of special material membranes in the form of a circle. After that, these circles are placed on appropriate nutrient Media and the number of microorganisms present is determined. This technique is most useful for CIP system or when there are places from which it is possible to collect final rinsing water.

Adenosine Triphosphate (ATP) or Bioluminescence Tests

This is the fastest method possible which gains result within minutes (Figure 4). It is very sensitive and can be used in combination with swabbing method. However, this method is not specific, i.e., it does not make differences between food residues and microorganisms. If used under defined conditions, it is possible to be a useful method.

Regardless of which technique is used, microbiological analysis will clearly indicate where and why the mistakes are made, which will allow food producers to take corrective actions before losing control over the production process.

Figure 4 ATP test.

Dry Cleaning

Facilities and premises (including rooms holding or storing packaged product and packaging material) which are dedicated to processing, handling, and storing dry foods may be solely cleaned by dry methods.

Dry cleaning can be applied in the cases where:

- The equipment and environment remains dry.
- Remaining dry, material does not present any risk of microbial growth to occur due to the present temperature, moisture, and humidity.
- Dry material which remains on the equipment contact surfaces as dust coverings or layers does not present any risk for quality of dry material subsequently produced.

- Dry material is nonhygroscopic and nonsticky.
- Good housekeeping procedures are preventing dust layers' accumulation in the environment or on the equipment where they may serve as breeding sites for vermins, especially insects.

Dry Cleaning Frequency

Cleaning frequency has to be determined from the:

- Microbiological evaluation of the types of raw materials used,
- Characteristics of the production process, and
- Nature of the food soils and the environmental residues.

Production process scraps has to be removed from dry processing areas at least once per day. Waste containers have to be clean and dry before they are returned to the processing area.

Dry Cleaning Equipment

Usual equipment for dry cleaning is:

- Brushes, scrapers, etc.,
- Vacuum cleaners, and
- Pressurized air.

Generally speaking, equipment which is used to clean food contact surfaces shall not be used for other purposes. Dry cleaning equipment has to be clearly marked and stored in a clean and dry location. In the cases where this equipment is removed from a dry processing area in the other area for the purposes of wet cleaning, then it has to be dried before it is returned in dry processing area.

If there are fatty food residues on the equipment surfaces, then brushes and scrapers can be used together with edible oil or appropriate food grade solvent (e.g., 70% ethanol). Brushes, scrapers, etc. shall be cleaned and sanitized in regular intervals and appropriate to the type of equipment.

When vacuum cleaning systems are used, for the purposes of efficient and frequent cleaning, there should be sufficient number of vacuum cleaners. Filters and dust bags have to be changed regularly, provided that removal of dust bags should be done away from food areas. Portable vacuum cleaners have to be protected from moisture during storage and transportation and in no way they should be dismantled for cleaning in food production and storage areas.

In the cases where pressurized air is used, special attention should be given to the fact that the air has to be contained within the internal equipment surfaces. Compressed air which comes in direct contact with food contact surfaces has to be filtered.

Dry Cleaning Methods

Dry cleaning methods have to be designed to minimize the creation of dust and airborne contamination. Also, there has to be a regular cleaning program for the filters and air-handling systems where dust extraction systems are installed. Generally, there are two dry cleaning methods: Manual cleaning and semiautomatic cleaning.

Manual Dry Cleaning

This method is focused on the main deposits and product layers removal by a vacuum cleaner, which is followed by brushing and/or scraping the surfaces.

As much as possible, dust formation should be avoided. Also, use of pressurized air should be avoided because this will result in creation of dust clouds that can be vector for transfer of contaminants to other areas.

Brushes, scrapers, and vacuum cleaners have to be easy accessible, regularly cleaned, and maintained. In the cases where equipment has to be dismantled in order to gain access, dismantling should be possible without the use of special tools. Use of damaged cleaning tools is prohibited because there is a risk of contamination with foreign material (broken parts from the cleaning equipment) that can remain in the equipment, pass to the dry food discharge area during subsequent operation, and contaminate product.

Nevertheless, the use of brushes and scrapers usually results in the recovery of a secondary quality grade material.

Semiautomatic Dry Cleaning

Semiautomatic cleaning procedures that are acceptable include the use of:

- Vacuum cleaners;
- dense particles (e.g., rice, plastic pellets, etc.) which are conveyed as an abrasive medium through ductwork handling dry material; and
- retractable nozzles and in-place air jets that sweep or blow dry material off a contact surface into the product collecting area. Use of air jets usually results with the recovery of dry material within the quality specification (provided that the surfaces being cleaned are not fouled with other material and the air used is filtered and have processing air quality).

This method requires availability of inspection ports, access points, and manholes for visual inspection of surfaces after cleaning.

Wet Cleaning in Dry Food Areas

Sometimes, in the dry food areas, wet cleaning is necessary as indicated earlier. The main reasons for this are when:

- Owing to present environmental temperature, humidity, and moisture content, dry material remaining in the equipment are present a real risk of microbial growth.
- Dry food material is hygroscopic and/or has a low softening point that gives rise to deposit formation on contact surfaces.
- Dry material remaining in the equipment represents a real risk of degrading the quality of the subsequently produced dry material.
- Any cross-contamination of dry material during a production change to another material cannot be permitted.
- Type of fixed and/or mounted processing equipment requires only wet cleaning.

In this case, the amount of used water and/or steam shall be kept to a minimum and contained within the immediate

area that is being wet cleaned. If the entire dry food area, including walls, floors, ceiling, equipment, etc., requires wet cleaning, then the amount of used water should be adequate to ensure that all residues are removed.

Before dry food production restart, everything that was wet cleaned (e.g., equipment, food surfaces, etc.) has to be free from food residues and moisture. Drying time should be shortened as much as possible. That is why forced hot air ventilation should be used where practical.

During wet cleaning in dry food areas, the use of sanitizers is recommended because they minimize the risk of microbial growth during drying. Also, after wet or dry cleaning, a 70% aqueous solution of ethanol or isopropanol may be used on equipment. This kind of solution is bactericidal, and the water vaporizes quickly, with the alcohol leaving the treated surface dry.

Air Disinfection

To clean the whole volume of the premises, air should also be disinfected. There are a few air disinfection systems such as:

Ultraviolet (UV) light irradiation,
Fogging, and
Ozone.

It should be noted that all the above mentioned air disinfection systems are not replacement for traditional methods for cleaning and/or disinfection.

UV Light Irradiation

UV light is one of the systems used for air disinfection as UV germicidal irradiation (UVGI) is considered UV light with wavelength of 2537 Å (254 nm). UV lamps for air disinfection can be part of low-power systems (lamp ratings from 15 to 100 W) or part of more powerful systems (medium pressure arc tubes with ratings from 0.5 to 5 kW). Most commonly used in UVGI applications are low-pressure mercury (Hg) discharge lamps.

According to Brown, dose needed for one decimal reduction varies widely between species (e.g., for *Legionella pneumofilia* – 2 mW s cm^{-2} and for *Aspergillus niger* – 132 mW s cm^{-2}).

UV light irradiation has two mayor drawbacks. One is that microorganisms which are in the shade will be not destroyed. That means that the UVGI lamps should be located in a manner that does not allow occurrence of shadows. The second drawback is that UV light with high intensity can cause eye cataracts and skin cancer. That is why, as a part of the designing systems, it is essential to establish proper screening and interlock devices.

Fogging

Fogging in the food production area has two goals:

1. To reduce the number of airborne microorganisms and
2. To apply disinfectant to surfaces that are difficult to clean (e.g., overhead surfaces).

This air disinfection system can be applied in chillers, freezers, process lines, processing areas, etc. This system is common for factories producing ready meals, dairy products, and sandwiches.

In general, there are two types of fogging solutions: wet (cold) and dry (thermal). The wet solution is a mist with particles that is applied in a fine spray. The dry type delivers the disinfectant as a gas with minimal moisture and can even be applied as a powder. Both types of fogger are effective as disinfecting agents for large areas where hand disinfection is not possible or practical. Both types of fogger materials are measured in microns to describe the miniscule size of the droplets or particles. Most effective fogging is when the medium diameter of fog droplets are between 10 and 20 μm, because they are dispersing well and settling within the timeframe of 45 min.

This air disinfection system also has its own drawbacks. First one is that during this procedure, personnel are excluded from the premises and the production process should stop. The second drawback is that this system is effective in reducing microbes only on upward facing surfaces, but in general, this is not effective on microbes on downward-facing surfaces.

Ozone

In the past decade, there was great interest in the food industry for using ozone as air disinfection agent. As antimicrobial agent, ozone was approved for use by the US Food and Drug Administration in 2001.

Various authors investigated effect of ozone on different microorganisms. Moore *et al.* found that gaseous ozone is effective against Gram-positive and Gram-negative vegetative bacteria at levels between 0.005 and 2 ppm. However, it is proven that the effect is time dependent. Bacterial endospores are much more resistant to ozone. According to Broadwater *et al.*, *Bacillus* spp. spores are 15 times more resistant than their vegetative cells. Different studies show that increased relative humidity increases the ozone effectiveness against bacterial spores. Most effective ozone disinfection takes place when the relative humidity is between 80% and 100%; no significant spores' inactivation occurs when the relative humidity is less than 50%.

Positive aspects of ozone air disinfection are that ozone:

1. Reduces the number of viable microbes attached to stainless steel surfaces and
2. Leaves no residue on the surface and can be used as terminal sanitizer for food contact surfaces.

However, ozone also has drawbacks. One of these drawbacks is that ozone is toxic to humans and even at 0.5 ppm can cause headaches and nausea. Exposure at 50 ppm for 30 min is fatal. The Health and Safety Executive (HSE) Guidance – Note EH 38 recommended exposure limit of 0.1 ppm as an 8 h weighted average and 0.3 ppm as a 15 min average for short exposure. This is the main reason to take special measures and care which will ensure that operators will not be exposed to ozone at the levels recommended previously. Second drawback is that ozone is highly reactive with many materials such as metals, textiles, organic dues, paints, different plastics, and natural rubber. The ozone can even react explosively with oils and grease. Therefore, thorough audit has

to be conducted before using ozone in order to replace the materials with alternatives that will not be degraded by ozone.

Allergen Cleaning and Validation

Food allergies are a food safety concern in the food industry. They represent one of the most important world health problems. Prevalence of allergic reactions worldwide is indicating an increasing trend over the past years. Studies elaborated in Europe and the USA is showing that food allergies affect up to 2% of adult population and up to 8% of children. Specifics of food allergens are that very low concentrations of allergen ingredients or components can trigger allergy reaction and the severity of the possible consequences for allergic people can be extreme. According to a European legislation, all food producers have to claim the presence of allergen ingredients on the declarations/labels of their packaged products, regardless of their concentration.

That is why each food producer has to establish an effective allergen management program that contains many elements including hygienic engineering and design, controls, formulations, operational methods, storage practices, scheduling, labeling, personnel practices, etc. The main pillar of this program is the allergen cleaning program. In this program allergen cleaning procedure has to be written in details.

Allergen Cleaning

Effective allergen cleaning is depending on following variables:

1. Soil type,
2. Surface texture, and
3. Cleaning method

Soil

The soil type depends not only on the allergen type but also on its form (e.g., different methods for removal of liquid eggs residue versus the removal of powdered eggs). Tree nut and peanut protein in most forms have high oil content, which require use of a detergent. Allergens which are in powdered form are typically creating a greater risk in product zones. The dusty nature of the ingredient/s is allowing airborne dispersal. That way, affected surfaces for powdered allergens will expand beyond the direct food contact surfaces. Particulate allergens are a problem in that they are not evenly dispersed throughout the product or the manufacturing equipment; therefore, if a particulate gets 'hung up' in the system, the contamination will be unevenly distributed in products which follow, i.e., contamination could be high in a small number of products.

Surface Type

Most of the food processing equipment is constructed from metals (stainless steel), elastomers, and plastics. Beside the fact that machinery and equipment should be free from any flaw (pits, imperfection, cracks, gaps, etc.), key issues regarding its cleanliness (including allergens) are correct selection of materials for equipment construction, matching the choice of material to the working environment, and their hygienic design.

Allergen Cleaning Methods

Allergens can be removed using following types of cleaning:

1. Wet cleaning,
2. Dry cleaning, and
3. Product purge (wet or dry).

As explained above in Section Wet Cleaning, wet cleaning involves water, often in combination with different types of chemicals. Nevertheless, it has to be clear that sanitizers do not remove residue, including allergen protein.

Dry cleaning does not involve water or chemicals. When speaking of allergen removal, used methods may include brushing, wiping, or vacuuming. The use of air hoses is strongly discouraged for allergen removal because the risk of dispersing the allergen is too great. Dry cleaning is especially appropriate for dry allergens with little to no oil content.

As cleaning method, product purge usually becomes an option when the surfaces that need to be cleaned are enclosed and not easily accessed, and the material that will be used for the purge can be recovered and reused in a formula that contains all of the material purged or is inexpensive and can be discarded. If product purge is used as the allergen removal method, then the amount of purged product has to be established in the appropriate procedure and validated through testing. It has to be stressed that product purge may address an allergen concern without addressing a microbial issue.

Allergen Cleaning Validation

Evidence of an effective allergen cleaning program cannot be the lack and/or absence of regulatory action or customer complaints. That is why the allergen cleaning program has to be validated and tested for each combination of soil, surface type, and cleaning method used. Validation process has to be precise and complete. Having in mind that any undeclared allergen/s is in fact a life-threatening contaminant, incomplete validation data or inaccurate data will result in risking human lives.

Generally, there are two approaches to testing:

1. Testing of cleaned surface and
2. Testing the product which is produced after cleaning.

Both testing methods have their own limitations, but if both types of testing are performed, then the most variables will be addressed.

Testing can be performed on site (with purchased test kits) or samples taken can be sent to outside laboratory/ies. Allergen-specific testing is necessary when validating allergen changeover cleaning because other types of postcleaning validation tests (ATP tests, general protein residual) will not provide the information which will demonstrate that allergen has been removed.

Usual procedures involved in testing are:

1. Running a product with an allergen.
2. Cleaning the line or equipment with the previously established method.
3. Swabbing the surfaces after cleaning and testing for the allergen in question and/or

   a. Sampling the first quantities of product from the subsequent run (product which is not containing the same allergen) and testing it for the allergen in question.
4. Holding all products produced in the subsequent run, until results have been obtained.
5. The results can show:
   a. Absence of detectable allergen, in which case the line or equipment may be used further and any product which was held may be released.
   b. Allergen carryover, in which case the held product has to be destroyed (or sometimes can be used in a formula which is declaring all carryover ingredients).
6. The line or equipment has to be recleaned (with a different method or can be variation of the same – modification of time, temperature, and/or chemical, etc.).

Allergen Cleaning Validation Frequency

The best approach is to perform validation of allergen cleaning at least once a year and whenever there are any significant changes in variables mentioned above (soil type, surface type, or cleaning method).

Also, if in the meantime more sensitive allergen test method has been developed, it is recommended to include that method in allergen cleaning validation.

Allergen Cleaning Verification

It is typically done using a documented observation by responsible staff, often the Quality Assurance personnel.

Hazard Analysis and Critical Control Point System (HACCP): Principles and Practice

CA Wallace, University of Central Lancashire, Preston, UK

Glossary

Control measure An action or activity that can be used to prevent, eliminate, or reduce a hazard to an acceptable level.
Corrective action Any action to be taken when the results of monitoring at the CCP indicate a loss of control.
Critical control point (CCP) A step at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.
Critical limit A criterion that separates acceptability from unacceptability.
HACCP plan A document prepared in accordance with the principles of HACCP to ensure control of hazards that are significant for food safety in the segment of the food chain under consideration.
Hazard A biological, chemical, or physical agent in, or condition of, food with the potential to cause an adverse health effect.
Hazard analysis The process of collecting and evaluating information on hazards and conditions leading to their presence to decide which are significant for food safety and therefore should be addressed in the HACCP plan.
Monitoring The act of conducting a planned sequence of observations or measurements of control parameters to assess whether a CCP is under control.
Prerequisite program Practices and conditions needed before and during the implementation of HACCP and that are essential to food safety. Alternative definitions: universal steps or procedures that control the operating conditions within a food establishment, allowing for environmental conditions that are favorable for the production of safe food; or, procedures, including good manufacturing practice, that address operational conditions, providing the foundation for the HACCP system.
Significant hazard Hazards that are of such a nature that their elimination or reduction to an acceptable level is essential to the production of safe foods.
Validation Obtaining evidence that the elements of the HACCP plan are effective.
Verification The application of methods, procedures, tests, and other evaluations, in addition to monitoring, to determine compliance with the HACCP plan.

An Introduction to the Internationally Agreed Approach to Food Safety Control

The hazard analysis and critical control point (HACCP) system is the internationally agreed approach to food safety control. The reference standard for implementation of HACCP is published by the Codex Alimentarius Commission of the joint United Nations Food and Agriculture Organization/World Health Organization Food Standards Programme. The HACCP approach is enshrined into legislation in many countries, for example, the European Commission Regulation on the hygiene of foodstuffs (EC N0. 852.2004), and it is widely recognized that the principles of HACCP are flexible and can be applied at any stage of the food chain anywhere in the world. HACCP can be applied by all food businesses, large and small, and also to improving food safety control in developing countries and even to food safety control in the home.

HACCP was developed as part of the US manned space program, where the National Aeronautics and Space Administration (NASA) collaborated with the US Army Natick Laboratories and the Pillsbury Company to develop an approach that would protect astronauts from foodborne illness. Following its success in the space program, HACCP was further developed by the Pillsbury Company who applied it to its own operations and launched the system to the food industry in the USA at the first National Conference on Food Protection in 1971. Although the principles of HACCP were further developed to become the internationally agreed approach to food safety management, the methods for HACCP principle application using multidisciplinary HACCP teams are still based on the original approach taken by Pillsbury in the USA in the 1970s.

The HACCP System and Food Safety Management

HACCP is a preventative approach to food safety management. It is designed to control significant food safety hazards, i.e., those hazards that are likely to cause an adverse health effect when products are consumed. This is achieved through the development, implementation, and maintenance of

 doi:10.1016/B978-0-12-378612-8.00358-9

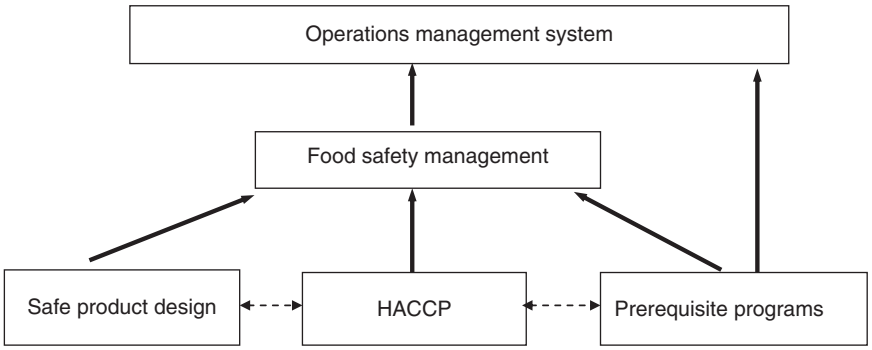

Figure 1 Manufacturing food safety management model. Adapted with permission from Mortimore SE and Wallace CA (2001) *HACCP – Food Industry Briefing*. Oxford: Blackwell Science.

the HACCP plan, a document that states how food safety hazards will be controlled in the food production operation. The HACCP System comprises the HACCP plan plus associated monitoring and verification records, which demonstrate that the HACCP plan is working in practice at all times. HACCP systems are developed through the application of the internationally agreed HACCP principles.

For food safety management to be effective, it is essential that HACCP be supported by good manufacturing practice or prerequisite programs (PRPs) that control the general hygiene and environmental conditions in a food processing operation. In a manufacturing operation, food safety management is achieved through the application of system 'building blocks' – safe product design, PRPs, and HACCP – operating under the framework of the overall operations management system (Figure 1).

The systems of the HACCP 'building block' are developed through application of the internationally agreed HACCP principles. For effective food safety management, all three 'building blocks' need to be adequately designed and their implementation be verified. Safe product design and PRPs are covered in more detail in other articles of this encyclopedia; however, it is useful to consider some key points here.

Safe product design relates to the intrinsic characteristics of the product, as determined by its recipe/composition, and to the processing methods and technologies used in its manufacture and the packaging, storage, and distribution mechanisms that protect the product once made. Although there are no defined principles of safe product design in the Codex documents, there is much published information about the elements of safe product design in other source documents. For example, the relationship between product intrinsic characteristics and the growth and survival of pathogenic microorganisms has been widely studied and is discussed in detail in texts such as those published by the International Commission on Microbiological Specifications for Foods. Similarly the effects of heat processes on microbial survival are widely cited in the literature and principles of hygienic design in food processing can be found in a wide range of publications. A key point is that product developers need to be considering food safety in the design of their recipe formulations and processes and that appropriate skills, knowledge, and experience are necessary to perform this adequately.

PRPs are the practices and conditions needed before and during the implementation of HACCP and which are essential to food safety. PRPs provide a hygienic foundation for the HACCP system by enabling environmental conditions that are favorable for the production of safe food. Like the HACCP system, there is an international agreement on the general principles required published by Codex and these essential characteristics of PRPs are laid out under the following headings for application to food chain establishments:

- Design and facilities.
- Control of operation.
- Maintenance and sanitation.
- Personal hygiene.
- Transportation.
- Product information and consumer awareness.
- Training.

Although Codex does not itself use the term PRPs, these requirements are generally accepted around the world as the essential areas where PRP elements must be developed, implemented, and maintained to provide environmental conditions that are favorable to the production of safe food and thus the foundations needed for effective HACCP systems.

PRPs are essential elements of any food safety management system and need to consist of formalized procedures and actions that will really provide a hygienic foundation for the HACCP system. To develop effective PRPs, personnel must have knowledge and experience of the current best practice in food hygiene management, as well as an appreciation of the key issues to be managed in their operation, for example, likely pest issues or constraints from building fabric.

PRPs are generally managed separately from the HACCP plan and are not normally involved in the management of CCPs because they are rarely designed to control specific significant hazards.

The HACCP Application Process

The process of HACCP plan development and implementation, through the application of the Codex HACCP principles, involves a number of interlinked stages (Figure 2).

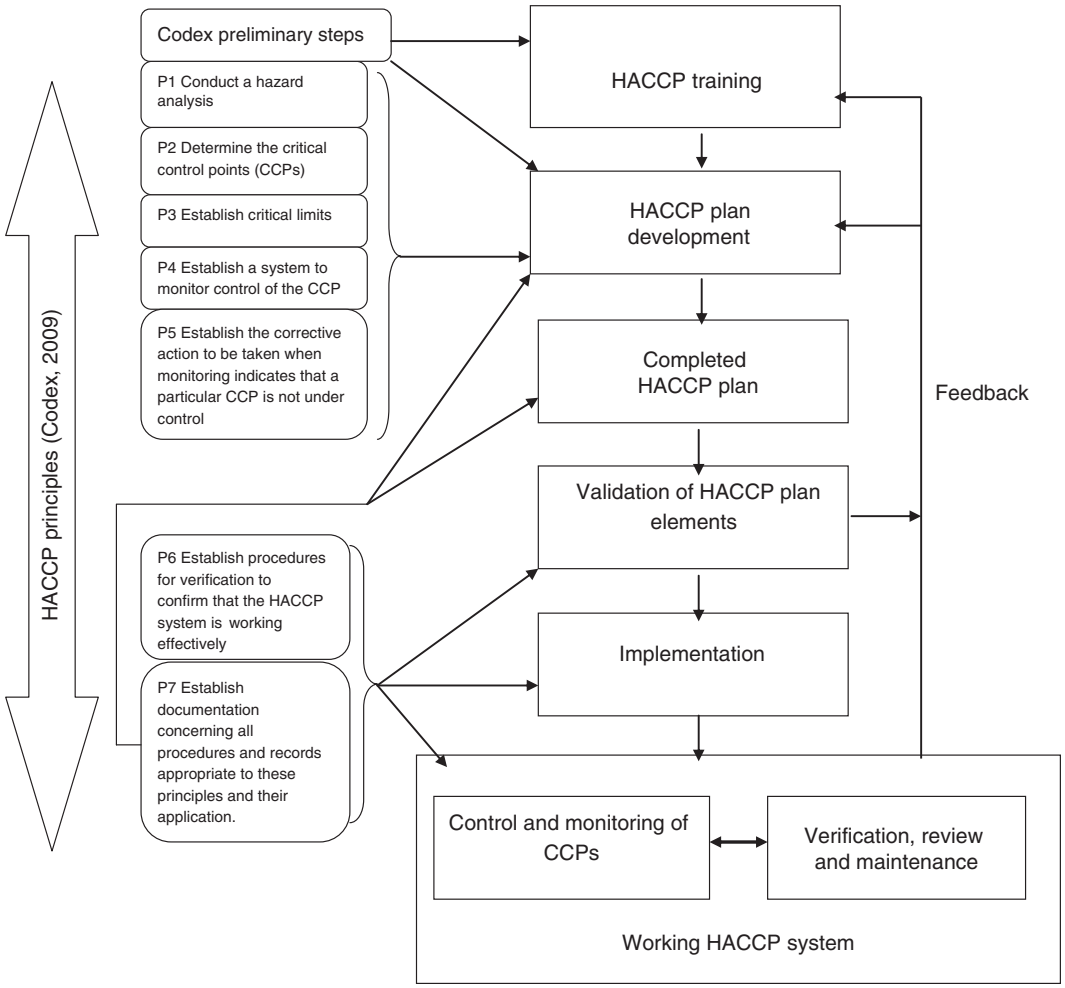

Figure 2 HACCP application process. Adapted with permission from Wallace CA, Powell SC, and Holyoak L (2005) Post-training assessment of HACCP knowledge: Its use as a predictor of effective HACCP development, implementation and maintenance in food manufacturing. *British Food Journal* 107(10): 743–759.

The HACCP Principles Explained

As indicated in Figure 2, the HACCP plan is established by applying the seven HACCP principles. Before examining in detail how to develop an HACCP plan, it is useful to briefly consider the requirements of each Principle (Table 1).

HACCP Documentation

The HACCP plan is defined as:

A document prepared in accordance with the principles of HACCP to ensure control of hazards that are significant for food safety in the segment of the food chain under consideration.

Put simply, the HACCP plan is the documentation produced that shows how significant hazards will be controlled. The HACCP plan is a formal document holding all details of areas critical to food safety management for a product or process. It consists of the:

Core Plan

- Valid process flow diagram.
- Documented CCP management details – this is usually captured in a table known as an HACCP Control Chart or CCP management table.

Support Documentation

This comprises the preparatory documentation that has been used in developing the HACCP plan as well as details of the verification requirements, including:

- HACCP team details.
- Product/process description (including terms of reference, consumer target group, and intended use of product).
- Hazard analysis details.
- CCP identification – details of approach and justification.
- HACCP verification plan.
- HACCP audit and review data.

Documenting the HACCP Study and HACCP Plan Development

Codex guidance on document organization (the HACCP Worksheet) is widely used as a basis for HACCP study records

Table 1 The HACCP principles explained

HACCP principle		*Clarification*
Principle 1	Conduct a hazard analysis	This requires the team to look at each process step one at a time, consider which hazards might occur, evaluate their significance, and establish how best to control them
Principle 2	Determine the CCPs	At this stage, the points that are critical to product safety are identified. This can be done through judgment and experience or using a structured tool – the Codex Decision Tree
Principle 3	Establish critical limit(s)	Critical limits are the safety limits that form the boundary between safe and potentially unsafe food. These need to be established to manage all CCPs
Principle 4	Establish a system to monitor control of the CCP	The monitoring system needs to demonstrate that the CCP is under control on a day-to-day basis and must be capable of detecting loss of control
Principle 5	Establish the corrective action to be taken when monitoring indicates that a particular CCP is not under control	If the CCP is not working, action needs to be taken to protect the consumer and to put right the cause of the deviation
Principle 6	Establish procedures for verification to confirm that the HACCP system is working effectively	This requires checking that the system is capable of controlling relevant hazards, is working in practice, and is up-to-date on an ongoing basis
Principle 7	Establish documentation concerning all procedures and records appropriate to these principles and their application	Documentation will include the process flow diagrams and tables created during the HACCP study (HACCP plans and development records) as well as monitoring records

Source: Reproduced with permission from Table 1 in Wallace CA, Sperber WH, and Mortimore SE (2011) *Food Safety for the 21st Century.* Oxford, UK: Wiley-Blackwell.

but there is no prescribed format and most companies use their own adaptations of recommended tables. A variety of templates are available in textbooks and in HACCP plan examples published on the Internet. The key requirement is to understand what needs to be documented not only to help the HACCP team in their deliberations during the HACCP study but also to ensure that all food safety hazards are identified, evaluated, and effectively controlled, and to provide evidence of an effective food safety system, for example, when being assessed by external auditors.

Developing a HACCP Plan

Application of the HACCP principles is done using a logical, step-by-step approach such that each step builds on the work done in applying the previous step. As shown in **Figure 2**, the HACCP principles are involved not only in the development of the HACCP plan but also in HACCP implementation and maintenance.

HACCP Study Terms of Reference and Scope

It is a standard practice to establish the scope or terms of reference at the start of any HACCP study. This should include the types of hazards to be studied (normally microbiological, chemical, and physical hazards); however, a particular study could focus on a specific hazard group, for example, when a specialist needs to be brought in to support the team.

Another important part of the terms of reference or scope is to identify exactly which part of the operation is to be covered by the HACCP study. This involves considering where the start and end points need to be and whether the HACCP study covers one product, a process involving several products, or a process module. Modular (or process-led) systems are practical to develop and are used in most manufacturing businesses, particularly those with complex processing operations, as well as in many foodservice operations. This is where the operation is split into a number of process sections and HACCP is applied to each section rather than to each individual product (the individual product approach is referred to as linear or product-led HACCP). With modular HACCP, a key point is to ensure that the modules add up to the entire operation and that no processes are missed out, so it is important to identify the start and end points accurately for each HACCP study and this is defined as part of setting the terms of reference and scope.

These details may be listed as an introduction to the HACCP plan or may be included in the product/process description.

Applying HACCP Principles – The Codex Logic Sequence

Before applying the HACCP principles, there are a number of preparatory steps that must be completed. These are described in the Codex logic sequence for the application of HACCP, as shown in **Table 2**.

Steps 1–5 are also known as the Codex preliminary steps to HACCP application and these were applied as part of the preparatory process before the use of HACCP principles.

Codex Logic Sequence Step 1: Assemble HACCP Team

Although this step tells us to 'Assemble HACCP Team,' it follows that before an HACCP team can be assembled, the correct people need to be identified and trained and it is therefore important to consider the key aspects of HACCP teams. The multidisciplinary HACCP team is believed to be one of the most powerful strengths of HACCP. Use of a team

Table 2 Logic sequence for application of the Codex HACCP principles

Logic sequence for application of HACCP	
Step 1	Assemble HACCP team
Step 2	Describe product
Step 3	Identify intended use
Step 4	Construct flow diagram
Step 5	On-site confirmation of flow diagram
Step 6	List all potential hazards, conduct a hazard analysis and consider control measures
Step 7	Determine CCPs
Step 8	Establish critical limits for each CCP
Step 9	Establish a monitoring system for each CCP
Step 10	Establish corrective actions
Step 11	Establish verification procedures
Step 12	Establish documentation and record keeping

ensures that HACCP plans are developed by a group of people who, collectively, have the knowledge and experience to take decisions about food safety.

The essential expertise within the HACCP team, therefore, includes:

- Personnel who understand the process operations, ingredients, and products on-site.
- Personnel who have knowledge and experience of the equipment, how it works to achieve process conditions, and the likely failure modes.
- Personnel who understand the likely hazards and appropriate control mechanisms, including how to validate process controls, including the necessary validation requirements.
- Personnel who have knowledge and experience of HACCP principle application.

This expertise is most likely to be gained by including personnel from a range of different disciplines within the food company, including Manufacturing/Operations, Quality/Technical, and Engineering disciplines. Additional specialists may also be required to provide knowledge and experience of specific aspects. Within the HACCP team, a leader needs to be appointed and a scribe or secretary identified. These are two crucial roles to the success of HACCP, ensuring that the HACCP development program is coordinated and kept on track, and that accurate records of all team discussions are maintained.

The total size of a HACCP team is normally kept to a maximum of four to six personnel for ease of management, although this 'core team' may not include the additional specialists who may be called in for specific tasks. In small operations, and even in some larger ones, it may be difficult to achieve a multidisciplinary HACCP team of this nature due to the limited number of appropriate personnel on-site. It is also likely that personnel in small businesses will have less knowledge of food safety hazards, and this will need to be compensated for by bringing in external support.

The multidisciplinary approach to HACCP works well and ensures that the system does not rely on the knowledge and experience of one individual. However, it is important that a balance of individuals is found and a 'sharing' environment promoted where job roles are left outside the door. This helps to overcome any difficulties from existing group norms such as inability to challenge more senior/dominant staff when necessary.

For an HACCP team to work effectively, all team members need to understand the application of HACCP principles. For best results, the whole team should be trained using a practical training intervention that covers both theory and practical application of HACCP. It is important to understand the balance of HACCP knowledge within the team such that the HACCP study process is guided by the team members with the best knowledge of HACCP principles. This might mean that one to two people with good HACCP knowledge are given the task of ensuring that HACCP plan development proceeds effectively whereas the remaining team members focus on their functional input to the team deliberations.

Having identified and trained the HACCP team members, the team will assemble to discuss and apply HACCP principles to the operation in order to develop HACCP plans.

Codex Logic Sequence Step 2: Product/Process Descriptions

This Codex Preliminary Step tells us to 'Describe Product'. In practice, this step considers information both about the product(s) and the process. The product/process description helps all HACCP team members to understand the background to the operations that they are about to study. It is most useful if the information is recorded formally as a 'product description' or 'process description.' This document then becomes a historical point of reference to the situation when the HACCP plan was developed and is useful both as a training tool for new personnel and briefing aid for internal or third-party auditors or regulatory inspectors.

The product/process description should include:

- Main ingredient groups to be used or 'work in progress' (WIP) inputs to process modules.
- Main processes and how materials are prepared/handled.
- Production environment and equipment layout.
- Hazard types to be considered, if known.
- Key control measures available through processes and prerequisites.
- Packaging/wrapping if appropriate to the scope of study.

When applying HACCP in foodservice operations, in addition to the general product description information listed above, it is a normal practice to group all the different menu/food items into like process groups at this stage, as this will help in developing process flow diagrams (Codex Logic Sequence Step 4).

Codex Logic Sequence Step 3: Identify Intended Use

It is important to identify the intended use of the product, including the intended consumer target group. Different consumer groups may have varying susceptibilities to the potential hazards, for example, the elderly, young children, or

immunocompromised individuals. However it must be emphasized that all products should be safe for all consumers.

Intended use considerations need to be examined throughout the product supply chain, including further manufacturers/processors, foodservice, retailers, through to handling and use by the final food preparer and consumer. Different uses of the food items may also need to involve different hazard considerations, for example, food items that may be cooked or used without any further heat process. The HACCP team needs to think about any ways that the product could be abused or used other than that intended.

Intended use and consumer group information is usually included as part of the process description record (from Step 2). In many cases it will be important to provide information to the consumer about how to handle, store, and prepare (including cooking as appropriate) the food item safely; and this can be derived once the intended use and potential misuse of the product is established.

Codex Logic Sequence Step 4: Construct Process Flow Diagram(s)

A process flow diagram, outlining all the process activities in the operation being studied, needs to be constructed. This should list all the individual activities in a stepwise manner and should show the interactions of the different activities. The purpose of the process flow diagram is to document the process and provide a foundation for the hazard analysis (Step 5).

To produce a flow diagram, it is necessary to separate the process into a series of steps. In the context of HACCP, the word 'step' refers not only to obvious processing operations but also to all stages that the product goes through, for example, incoming raw materials, storage, etc. The diagram should progress logically and relate to how the product is actually produced, and should contain enough detail to allow an understanding of the process. The steps should be listed as 'activities,' i.e., what is happening at this step, and the time and temperature information should be included where relevant. A common error in HACCP is to list the names of the process equipment rather than the process activity and to miss out transfer steps. This often results in an incomplete process flow diagram, which makes the process difficult to follow.

The most commonly used type of flow diagram for use in HACCP studies shows ingredients or groups of ingredients along the top of the page through to the end point with the finished product(s) at the bottom. This gives a realistic interpretation of what actually happens from the starting point of listing ingredients to the end of production.

The style of process flow diagram will also depend on how the HACCP system is structured for the operation and the terms of reference/scope of the HACCP study. In most manufacturing operations, unless the process is very simple, the modular approach to HACCP will be used and this means that there will be a series of process flow diagrams comprising the different processes. Only the initial modules will show the handling of ingredients but later modules should show the incoming inputs from the previous module, for example, work-in-progress (WIP) or part-produced items. In foodservice operations, process flow diagrams will be generalized to cover the processes for the key recipe groupings but will not show individual ingredients or specific menu items.

Full detail of all process activities, storage, and transfer steps are needed in the HACCP study to allow a thorough hazard analysis to take place. This requires a very detailed layout to be prepared by the HACCP team, ensuring both that the process is easy to understand and that the diagram is representative of what actually happens.

Codex Logic Sequence Step 5: On-Site Confirmation of Flow Diagram

As the process flow diagram will usually be developed in the office away from the processing activities and it will be used as a tool to structure the hazard analysis, it is important to check and confirm that it is correct. This is done simply by going into the process area and comparing the documented diagram with the actual process activities, noting any changes necessary, and making sure that all variations, for example, on different shifts, are covered. This exercise is normally done by members of the HACCP team or production personnel, but it is good to have someone independent to confirm the process flow as the on-site HACCP/production team may be too close to the processes and either miss out points or make assumptions. The completed process flow diagram should then be signed off and dated as valid and it is important to make sure that this is done before the hazard analysis commences.

Codex Logic Sequence Step 6: List all Potential Hazards, Conduct a Hazard Analysis and Consider Control Measures (Apply HACCP Principle 1)

Using the process flow diagram(s), the HACCP team considers each process activity in turn and lists any potential hazards that might occur, then performs an analysis to identify the significant hazards and suitable control measures. A number of key HACCP terms are introduced at this stage and these are defined by Codex as follows:

Hazard: A biological, chemical, or physical agent in, or condition of, food with the potential to cause an adverse health effect.

Hazard analysis: The process of collecting and evaluating information on hazards and conditions leading to their presence to decide which are significant for food safety and therefore should be addressed in the HACCP plan.

Control measure: An action or activity that can be used to prevent, eliminate, or reduce a hazard to an acceptable level.

Hazard analysis is a key element of HACCP and will determine the strength of the resulting HACCP plan. The hazard analysis needs to be accurate and specific – including detail about the type of hazard and its source or cause, as well how the significance of specific hazards was determined and justified. If the hazard analysis is too brief or too general, then the following steps in the HACCP study will be more difficult and the HACCP plan is likely to be weak.

For microbiological hazards, it is possible to generalize to a certain extent, but consideration should be given to specific pathogens. Microbial hazards are normally listed as specific organisms, for example, *Listeria monocytogenes* or *Salmonella* spp., or using the collective terms, vegetative and spore-forming pathogens. The cause or source of the hazard needs to

be established along with how the hazard is manifested in the process, that is:

- Presence of the hazard in a raw material.
- Contamination with the hazard during processing and handling.
- Growth of microorganisms during production.
- Survival of microorganisms through a failure in a process designed to destroy them.

This detail is important to understand the most appropriate control measures as, for example, growth of a particular hazard will need a different control measure for contamination with a hazard.

For physical hazards, it is important to consider whether the item would genuinely cause physical harm to the consumer. Physical hazards are:

- Items that are sharp and may cause injury.
- Items that are hard and may cause dental damage.
- Items that could block airways and cause choking.

For chemical hazards, the hazard analysis will consider the likelihood or presence of toxic chemicals in the raw materials and contamination by chemicals during processing, which may raise the toxicity to an unacceptable level. The issues involved with food allergens that may cause hypersensitivity reactions in susceptible consumers are normally considered under the chemical hazards group, and will be managed by HACCP and PRPs.

Chemical contaminant hazards are, perhaps, the least well-understood group of hazards within food company HACCP teams as few companies employ toxicology specialists. Therefore, this is an area of HACCP where most companies need to seek external advice to understand the likely chemical hazards in their operations. Nevertheless, HACCP can be applied successfully to the control of chemical hazards both as raw material hazards and processing contaminants. Motarjemi *et al.* (2009), provided a case study on the application of HACCP in managing process contaminants that HACCP teams may find useful as a basis for discussion.

The process of hazard analysis includes:

- Hazard identification – Identifying which hazards may occur and where.
- Assessment of significance – Establishing which hazards are likely to occur and cause an adverse health effect.
- Identification of control measures – Establishing an effective mechanism for ongoing control of each significant hazard.

A common approach to documentation of the hazard analysis is the use of Hazard Analysis Charts. Hazard analysis charts (**Table 3**) are used to help structure the hazard analysis, allowing HACCP teams to document the important aspects with respect to potential hazard identification, reasoning, and decision making regarding significance and determination of appropriate control actions. This level of detail is important to the production of the HACCP plan and provides useful information for any future challenges of the HACCP plan, for example, through external audit.

Determination of hazard significance

Codex requires 'control of hazards that are of such a nature that their elimination or reduction to acceptable levels is essential for the production of a safe food' and states that the process of hazard analysis is intended to 'identify those hazards that are significant for food safety and therefore should be addressed in the HACCP Plan.' Although the term significant hazard is not defined by Codex, the International Life Sciences Institute has put these two phrases together to form a useful definition:

Significant hazard: Hazards that are of such a nature that their elimination or reduction to an acceptable level is essential for the production of safe foods.

To identify the significant hazards, it is necessary to consider the likelihood of occurrence of the hazard in the type of operation being studied as well as the severity of the potential adverse effect. A significant hazard, therefore, is one that is both likely to occur and cause harm to the consumer (**Figure 3**).

Most companies will assess significance of hazards using judgment and experience but structured 'risk evaluation' methods, where different degrees of likelihood and severity

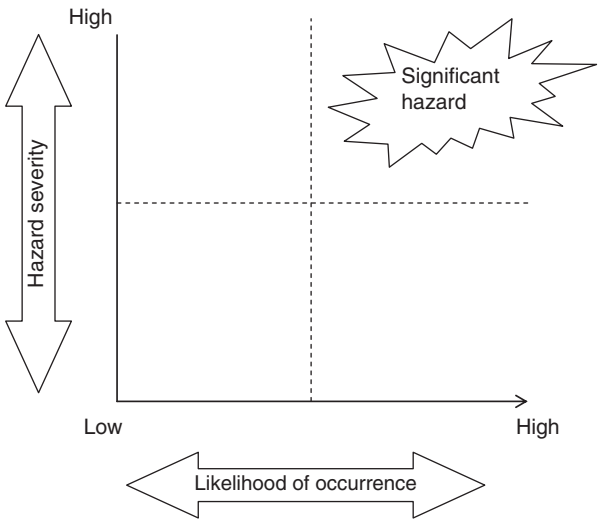

Figure 3 Hazard significance assessment. Reproduced with permission from Mortimore SE and Wallace CA (1998) *HACCP – A Practical Approach*, 2nd edn. Gaithersburg, USA: Aspen Publishers Inc.

Table 3 Possible Hazard Analysis Chart headings

Process step	*Hazard: Source, cause, and manifestation*	*Likelihood of occurrence (high/low)*	*Severity of outcome (high/low)*	*Significant? (yes/no)*	*Justification of significance decision*	*Control Measure(s)*	*Justification of control measures*

are weighted, are sometimes used to help with the significant decision. Risk evaluation decisions should be taken from a sensible viewpoint based on knowledge and experience. Structured risk evaluation methods often involve significance assessment tables, which aim to consider the degree of likelihood and the severity of effect by rating these as 'high,' 'medium,' or 'low' (Table 4). This is similar to the concept shown in Figure 3 but aims to put individual hazards in boxes to assist with the significance decision.

Although these tools are generally believed to make significant assessment more straightforward by the companies using them, individual tools need to be proven to be effective and require training in their application and use of judgment to position the identified hazards in the correct subcategories, i.e., a tool such as Table 4 is only useful if there is also guidance on which boxes are equivalent to significant hazards. Currently, there are no definitive rules on this within HACCP. There has been a resurgence in the use of these risk evaluation tools in recent years, which is believed may be linked to uptake of the International Organization for Standardization 22 000 audit standard, Food safety management systems – Requirements for any organization in the food chain. This requires formal records of hazard assessment to be maintained, although there is no specific requirement in the standard for any particular tool to be used.

The most important point is that the decision on hazard significance is based on appropriate knowledge and experience, and is not clouded by the inappropriate use of unproven decision-making tools. Further assistance to consider when carrying out the hazard analysis is provided by Codex, which lists some brief points (Table 5) to help the HACCP team discuss different hazard issues.

Table 4 Example significance assessment table

		Likelihood of occurrence		
		High	Medium	Low
Severity of effect	High			
	Medium			
	Low			

Control measures

Once the significant hazards have been established, effective control measures need to be identified for each significant hazard. As defined above, control measures are the actions that can be used to prevent, eliminate, or reduce a hazard to an acceptable level. Control for each significant hazard is essential but there may be more than one control measure for any hazard. There will also be control measures operating for PRPs.

Control measure options include:

- Process steps, for example, cooking, sieving, and metal detection.
- Product intrinsic factors.
- Use of approved suppliers.
- Temperature controlled storage or holding.
- Handling procedures.
- Controlled segregation.

An important point about control measures is to make sure that they are capable of ongoing control of the hazard at all times. Often HACCP teams mistakenly identify monitoring checks as 'control measures' rather than genuine controls – the measure must be control not monitoring and effective control measures must relate to the hazard and source, be comprehensive and appropriate, and be effective at controlling the significant hazard.

When deciding on control measures, it is important to consider the different options that may be available to control the particular hazard in order to establish the best method for control. This can include an evaluation of the measures currently in place, but it is important to decide whether these are strong enough or if additional control is necessary.

Codex Logic Sequence Step 7: Determine CCPs (HACCP Principle 2)

CCPs are the points in the process where the significant hazards must be controlled, and are defined by Codex as follows:

CCP: A step at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Table 5 Codex guidance on application of HACCP Principle 1

List all potential hazards associated with each step, conduct a hazard analysis, and consider any measures to control identified hazards

The HACCP team should list all of the hazards that may be reasonably expected to occur at each step according to the scope from primary production, processing, manufacture, and distribution until the point of consumption. The HACCP team should next conduct a hazard analysis to identify for the HACCP plan whose hazards are of such a nature that their elimination or reduction to acceptable levels is essential to the production of a safe food

In conducting the hazard analysis, wherever possible the following should be included:

- The likely occurrence of hazards and severity of their adverse health effects
- The qualitative and/or quantitative evaluation of the presence of hazards
- Survival or multiplication of microorganisms of concern
- Production or persistence in foods of toxins, chemicals, or physical agents
- Conditions leading to the above

Consideration should be given to what control measures, if any exist, can be applied for each hazard.

More than one control measure may be required to control a specific hazard(s) and more than one hazard may be controlled by a specified control measure

Source: Reproduced with permission from Codex (Joint FAO/WHO Food Standards Programme, Codex Alimentarius Commission) (2009a) *Food Hygiene Basic Texts*, 4th edn. Rome: Joint FAO/WHO Food Standards Programme, Food and Agriculture Organization of the United Nations.

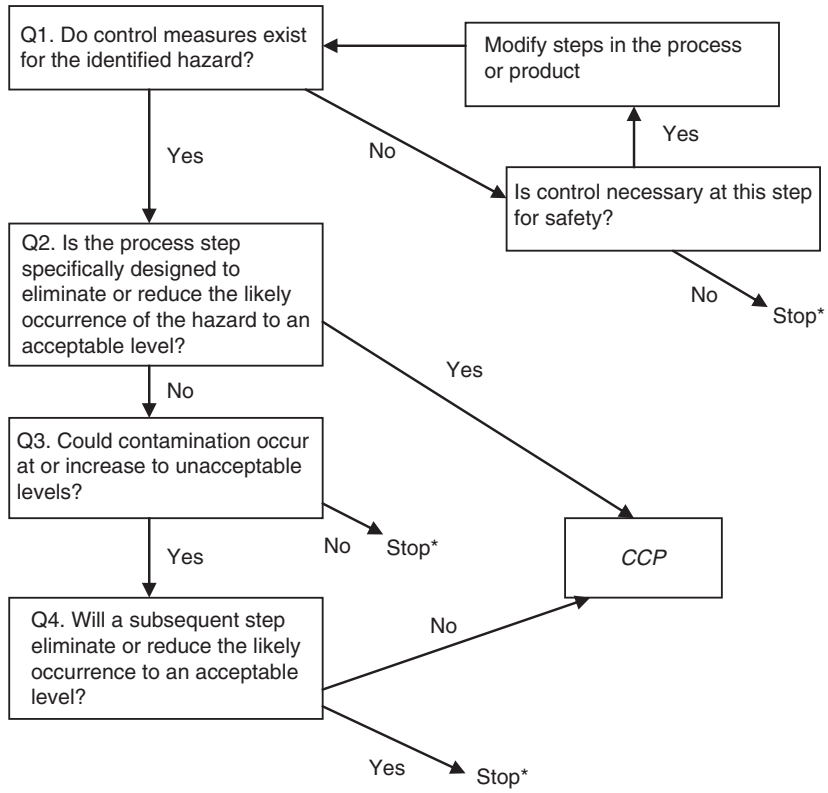

Figure 4 CCP decision tree. Adapted from Codex (Joint FAO/WHO Food Standards Programme, Codex Alimentarius Commission) (2009a) *Food Hygiene Basic Texts*, 4th edn. Rome: Joint FAO/WHO Food Standards Programme, Food and Agriculture Organization of the United Nations.

CCPs can be identified using HACCP team knowledge or experience and by using tools such as the Codex CCP Decision Tree (Figure 4).

The Codex CCP decision tree is a useful tool that is widely used by HACCP teams. To use the decision tree, the questions are asked in sequence for each significant hazard that has been identified for each process activity (Table 6). This discussion of Codex decision tree application is reproduced from Wallace *et al*. (2011).

When working with the decision tree, it is useful to keep a record of the team's discussions and justification of the decisions for future reference. This is normally done using a CCP Decision Record Sheet such as the following example (Table 7). Even if the team is not using the decision tree, it will be important to keep a record of the decisions so that full evidence of the HACCP process is available to show regulators and auditors.

Once the HACCP team has worked through the processes for all the hazards, a list of CCPs will be available. These are the points in the processes that must be carefully managed to make sure that the food produced is safe. For each of the CCPs, it is now important to define how they will be controlled and managed on a day-to-day basis. HACCP Principles 3–5 are applied to set these standards, and normally this information is recorded in a HACCP Control Chart or Table such as the following example (Table 8).

Codex Logic Sequence Step 8: Establish Critical Limits for Each CCP (HACCP Principle 3)

Critical limits are the safety limits that must be achieved for each CCP to ensure that the food is safe. If the process operates beyond the critical limits, then products made will be potentially unsafe. Critical limits are defined by Codex as follows:

Critical limit: A criterion that separates acceptability from unacceptability.

Critical limits are expressed as absolute values (never a range) that define the barrier between 'safe' and 'potentially unsafe.' They often involve criteria such as temperature and time, pH and acidity, moisture, etc. Critical limits must be measurable and must be established for all CCPs. The choice of critical limit can be based on scientific and experimental data, industry or legislative standards, and historical evidence. Another measure that is often used for practical purposes in food operations is the 'target level' or 'operational limit.' The difference between critical limits and operational limits is that operational limits are set at 'tighter' parameters than required for safety, thus providing a buffer zone for process management by indicating if a CCP is moving out of control.

It is important to know that everyday process parameters would achieve the critical limit, along with what the margin of error is, and this is done by validating the process, which will be discussed in more detail later in Codex Logic Sequence Step 11.

Table 6 Applying the Codex decision tree questions

Q1: Do control measures exist for the identified hazard?	In most cases, when conducting the hazard analysis (Step 6), control measures will have been identified for the significant hazards. Therefore, it is most common to answer 'yes' to Q1. However, if the HACCP team could not identify a control measure, then it is necessary to answer 'no' and move on to the sub-question Q1a
Q1a: Is control at this step necessary for safety?	Perhaps control is not necessary at this process step for safety, for example, there might be a control measure later in the process. In this, the answer 'no' results in the decision that this step is not a CCP for that particular hazard and the instruction to stop/proceed (move on to the next hazard). However, if the HACCP team considers that control is necessary at this step for safety (perhaps there is no control later), then the answer 'yes' results in the decision tree instruction to 'Modify step, process or product,' that is carry out some modification to allow a control measure to be built in For example, if you were concerned about metal hazards entering a process but had no control measure later on that could remove them, it would be possible to carry out a modification to build in control through a suitable metal hazard removal system such as magnets or metal detection later on in the process Once a modification has been determined, the team needs to go back and ask Q1 again. Now they will be able to answer 'yes' and move on to Q2. A key point to remember is that if you cannot establish a CCP for a significant hazard, then you cannot make the product as it would always be potentially unsafe for consumption
Q2: Is the process step specifically designed to eliminate or reduce the likely occurrence of the hazard to an acceptable level?	This is a key question in the decision tree and one that people often have difficulty with. The question provides, in effect, a shortcut to a CCP decision for those process steps that are designed to control hazards, for example, most cooking processes. The important thing to remember is that the question is asking about the process step and not the control measure. This is because control measures are always designed to control hazards so would always result in the answer 'yes.' Because you are asking the question about control measures, and a CCP is identified every time you answer 'yes,' the result could be many more CCPs than are actually required. To make matters slightly more confusing some process steps are also control measures – these are the ones that this question is designed to find Where cooking processes are not specifically designed to control hazards, then the team should answer 'no' rather than 'yes.' Not all cooking steps are CCPs – some are at such high heat processes, designed to change the physical structure of the product rather than for safety (e.g., some baking processes), that a significant hazard such as vegetative pathogens simply could not survive. In other words, the likelihood of occurrence should have been established as 'low' during the hazard analysis and it will not be a significant hazard. Although this should have been identified at the hazard analysis stage, and therefore not be an issue during CCP decisions, some companies find in practice that customers and/or regulators insist on such steps being CCPs, even when there is clear justification that this is not required If the team believes the answer to this question is 'no,' they should progress onto Q3
Q3: Could contamination with identified hazard(s) occur in excess of acceptable level(s) or could these increase to unacceptable levels? Note: Acceptable levels are safe for consumption and unacceptable levels may cause harm to the consumer	If a significant hazard has been identified, then this is really already saying that something unacceptable could occur. Therefore, in most cases the answer to this question will be 'yes.' However, the question does give the chance to just think again and confirm whether it is unacceptable or acceptable. Sometimes use of the loop at Q1a resulting in a process modification, might mean that the hazard(s) are no longer considered unacceptable (perhaps they have been designed out of the process completely) and so the answer would be 'no' in this case. Where you have answered 'yes' to this question move onto Q4, otherwise stop and proceed with the decision tree for the next hazard
Q4: Will a subsequent step eliminate the identified hazard(s) or reduce their occurrence to acceptable levels?	This last question allows the presence of a hazard at one process step if it is going to be effectively controlled at a later process step. It is helpful in keeping the CCPs to a manageable number, whilst making sure that the essential ones are identified. If there is a subsequent step in the process where the hazard will be controlled ('yes' answer) then the current process step is not the CCP but the later step will be. It is important to check that the later process step is properly identified as a CCP when the team gets to the end of the study. If there is no subsequent process that will control the hazard then the current step needs to be made a CCP and managed accordingly

					Procedure	*Frequency*	*Responsibility*	*Procedure*	*Responsibility*

Codex Logic Sequence Step 9: Establish a Monitoring System for Each CCP (HACCP Principle 4)

Once the critical limits, and operational limits, have been established, the next step in HACCP involves developing a monitoring system for ongoing measurement, which will demonstrate that the CCPs are working effectively. Codex defines monitoring as:

Monitoring: The act of conducting a planned sequence of observations or measurements of control parameters to assess whether a CCP is under control.

Monitoring is necessary to demonstrate that the CCPs are being controlled within the appropriate critical limits and monitoring requirements need to be specified by the HACCP team during the HACCP study. Each monitoring activity should have a person who is allocated to carry it out (CCP monitor) and record the results and take any necessary actions. In manufacturing, monitoring is usually done by production line personnel who are involved in operating the processes where the CCPs are located. The frequency of monitoring should also be defined and this will require consideration of the process speed/throughput. The ideal situation is to have continuous monitoring systems linked to alarm and action systems.

Codex Logic Sequence Step 10: Establish Corrective Actions (HACCP Principle 5)

Corrective action needs to be taken where monitoring shows that there is a deviation from a defined critical limit. Corrective actions must deal with both the product produced while the process is out of control (it may need to be destroyed or reprocessed) and with the process fault that has caused the CCP deviation in order to bring the process back under control. Codex defines corrective action as follows:

Corrective action: Any action to be taken when the results of monitoring at the CCP indicate a loss of control.

Corrective action procedures and responsibility need to be identified by the HACCP team during the HACCP study such that they can be implemented by the appropriate operations personnel if deviation occurs. Corrective action is not 'contact the Quality Manager' for every event but specific actions that will handle potentially unsafe product and bring the process back under control. The effectiveness of the proposed corrective action plan needs to be verified and challenged as this is the last defense mechanism protecting the consumer from receiving potentially unsafe product should a CCP fail.

Codex Logic Sequence Step 11: Establish Verification Procedures (HACCP Principle 6)

Verification requires that procedures are developed to confirm that the HACCP system can and is working effectively. There are actually two different types of confirmation required – validation and verification. Many people find the terms validation and verification confusing, partly because the words sound similar and partly because they are both part of the verification principle (Principle 6). They are separate and different activities and it is helpful to consider the definitions in more detail to help understand the difference.

Validation — Codex definition: Obtaining evidence that the elements of the HACCP plan are effective

Clarification

- Is the HACCP plan capable of controlling all relevant hazards if correctly implemented? or
- Will it work?

Verification — Codex definition: The application of methods, procedures, tests, and other evaluations, in addition to monitoring, to determine compliance with the HACCP plan.

Clarification

- Is there compliance with food safety requirements defined in the HACCP plan or
- Is it working in practice?

Validation will include:

- Cross-checking through the HACCP plan to make sure that all the principles have been correctly applied.
- Checking that the hazards will be controlled, i.e.,
  - The control measures are suitable.
  - Correct CCPs have been identified.
  - Critical limits are set correctly for the hazard, for example, using literature values, challenge testing, etc.
  - Process will achieve the critical limit(s), for example, the process is capable of always achieving this limit within normal process variation.
  - Monitoring will detect loss of control if it happens.
  - Corrective action will prevent the potentially unsafe food being consumed.

Validation can be done by HACCP team members working with other managers within the business. As with preparing the HACCP plan, it will be better to involve more than one

person if possible and, like hazard analysis, this will be an area where many companies will need to use expert resource from outside the company to assist in validation.

Commonly used verification procedures include:

- HACCP audits.
- Review of CCP monitoring records.
- Product testing – microbiological and chemical tests.
- Review of deviations, including product disposition and customer complaints.

Verification can also be done by HACCP team members or other personnel within the business, for example, supervisory staff. It is important to have independence from the system to audit effectively so consideration can be given to using external resource or other personnel who were not involved in developing or in the day-to-day running of HACCP. Auditors should be competent in both HACCP application and audit skills.

Codex Logic Sequence Step 12: Establish Documentation and Record Keeping (HACCP Principle 7)

It is important to document the HACCP system and to keep adequate records. The HACCP plan will form a key part of the documentation, outlining the CCPs and their management procedures (critical limits, monitoring, and corrective action). It is also good practice to keep documentation showing how the HACCP plan was developed, i.e., the hazard analysis, CCP determination, and critical limit identification processes.

When the HACCP plan is implemented in the operation records, will be kept on an ongoing basis. Essential records include:

- CCP monitoring records.
- Records of corrective actions associated with critical limit deviation.
- Records of verification activities.
- Records of modifications to processes and the HACCP plans.

The key consideration for all businesses should be to have sufficient documentation to demonstrate the effective working of the HACCP system. Maintenance and archiving of HACCP records is therefore an important element of effective HACCP. Records may be kept as paper archives; however, increasingly companies are turning toward computerized record-keeping systems.

Activities for Implementation of an HACCP Plan

The implementation stage is where the HACCP plan documents are translated from paper documents owned by the HACCP team to a working system managed by operations personnel. Training is therefore a key requirement, including training for the personnel who will monitor CCPs and take corrective action, along with HACCP awareness training for the wider operations workforce. Implementation needs to be carefully planned, with responsibility for various actions given to the appropriate people. It is not simply a case of handing

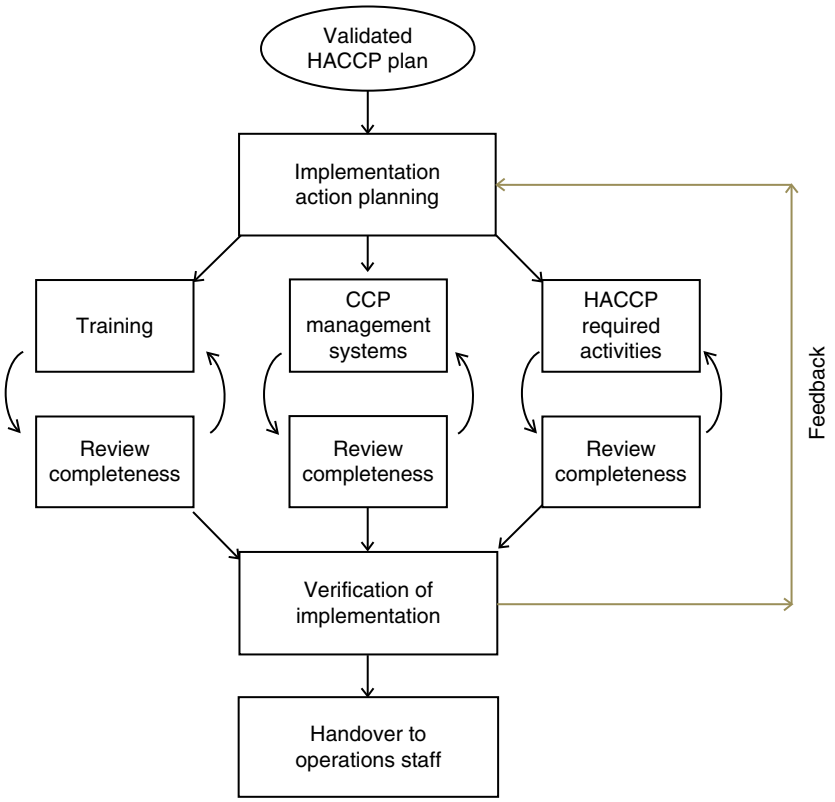

Figure 5 Steps to HACCP implementation. Reproduced with permission from Wallace CA, Sperber WH, and Mortimore SE (2011) *Food Safety for the 21st Century*. Oxford, UK: Wiley-Blackwell.

the HACCP plan documentation over to the operations personnel; rather there is a need for detailed and careful planning such that all the required activities for successful implementation can be identified and progressed. This is best achieved by breaking the necessary activities down into individual steps (Figure 5).

Maintaining HACCP and Food Safety Management Systems

Maintenance of a food safety program requires several key fundamentals:

- Challenging the effectiveness of the program elements.
- Ensuring that the program remains up-to-date, both with the ingredients, processes, and operations on-site; and with changing knowledge on food hygiene and food safety hazards.
- Making certain that the program remains suitable, both for the provision of adequate hygiene foundations (PRPs) and for the effective control of all relevant food safety hazards (HACCP plans).

Effective food safety program maintenance requires the application of a range of different techniques and approaches and the involvement of personnel from different roles and areas of the operation. Tools will include audit and management review alongside a variety of specific test procedures, and it will be important for personnel to have appropriate skills, for example, in auditing and information searching/update. It is important that all maintenance procedures are formally managed as part of the company's ongoing operations management procedures.

The key elements of food safety program maintenance are illustrated in Figure 6.

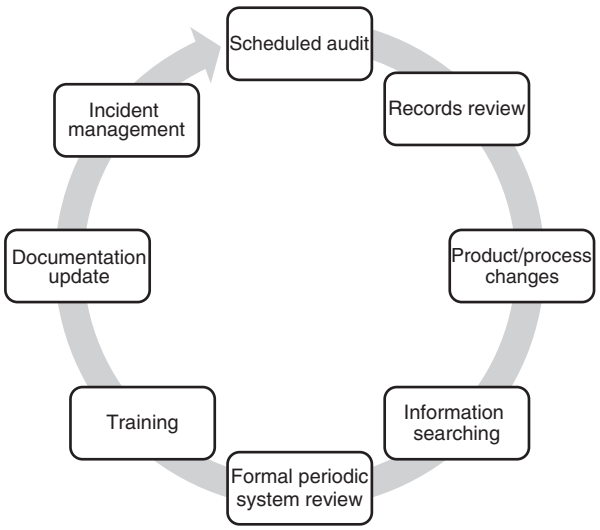

Figure 6 Elements of food safety program maintenance. Reproduced with permission from Wallace CA, Sperber WH, and Mortimore SE (2011) *Food Safety for the 21st Century*. Oxford, UK: Wiley-Blackwell.

Effective HACCP-Based Food Safety Management

As discussed in this article, application of HACCP principles is achieved by following a straightforward step-wise procedure outlined by the Codex Logic Sequence. This will only result in an effective HACCP system if performed by HACCP teams made up of personnel with the correct blend of training, skills, and experience. The outcome of this HACCP study process should be a HACCP plan that clearly defines how all significant hazards relevant to the operation will be controlled.

The preventative nature of the HACCP approach to the management of food safety comes through its identification, evaluation, and control of hazards that could cause harm to the consumer. HACCP should be effective in that it proactively identifies potential food safety hazards and implements control systems before the hazards are realized. However, HACCP cannot guarantee zero tolerance for all food hazards 100% of the time due to variability in materials and processes in conjunction with the potential for control procedure failure and human error, so it should be considered a risk management system that can minimize the likelihood of food safety hazards occurring. A rigorously designed, fully implemented, and securely managed and controlled HACCP system – i.e., 'effective HACCP' – should come as close to zero tolerance as technically and operationally feasible in a food operation. This, combined with safe product design and proven PRPs, will provide effective HACCP-based food safety management programmers as a cornerstone of public health protection.

Disclaimer

As the author of this article is an established writer in the field of HACCP, out of necessity this article draws on previously written source material, in particular the following: Mortimore and Wallace (1998), Mortimore and Wallace (2001), Wallace (2009), and Wallace *et al*. (2011).

FOOD SAFETY ASSURANCE SYSTEMS

Management of Biofilm Risk

G Wirtanen, VTT Expert Services Ltd., Espoo, Finland
M Raulio, VTT Technical Research Centre of Finland, Espoo, Finland
S Salo, VTT Expert Services Ltd., Espoo, Finland

Glossary

Biofilm Surface-attached structured matrix-enclosed microbial communities.
Biofouling Biofilm formation including organic matter on equipment surface.
Cleanroom A room in which the concentration of airborne particles is controlled, and which is constructed and used in a manner to minimize the introduction, generation, and retention of particles inside the room, and in which other relevant parameters, for example, temperature, humidity, and pressure, are controlled as necessary.
Contact agar method Detection method for microbes on surfaces based on contact sampling with suitable nutrition agar of microbes on surfaces and their growth on the agar substrate.
Hygienic design Simple and cleanable structure for equipment, which is utilized according to rules stated in guidelines.

Biofilm Formation

Microorganisms exist predominantly as sessile multispecies communities in natural habitats. These surface-attached highly structured matrix-enclosed microbial communities are known as biofilms.

Biofilms occur in a wide range of environments, on every surface when supplied with moisture and nutrients. Biofilms can exist in natural ecosystems, for example, river stones and surfaces of a plant, or in ecosystems connected with disease, for example, teeth and the mucosal membranes of animals, as well as in manmade ecosystem, for example, steel surfaces of industrial equipment, heat exchangers, and water pipes.

The biofilms usually consist of microcolonies formed by multiple microbial species embedded in an extracellular matrix. The composition of the extracellular matrix, i.e., extracellular polymeric substance, is as diverse as the biofilm-forming microbial species. It is usually composed from polysaccharides, proteins, nucleic acids, and cell components with concentrated minerals and nutrients from the surrounding environment. As the population in a biofilm grows, the individual microbial cells may differentiate and take on specific tasks enabling the formation of a defined architecture of shapes resembling mushrooms or towers connected by a network of water channels responsible for the transport of nutrients, oxygen, and wastes.

The complex structures of biofilms with a high level of differentiation among biofilm cells require cell-to-cell signaling, i.e., quorum sensing. When a bacterium starts to form a biofilm, it switches from single cell to multicellular lifestyle by up and down regulating specific genes. Even in single-species biofilms, individual cells express their genes in a pattern that differs from one cell to another and from the planktonic cells of the same species. It is suggested that biofilms hold microniches with varying gradients of nutrients due to metabolic activity of sessile cells. These small ecosystems create conditions for spontaneous mutations to occur. Different cell types in biofilm provide genetic diversity for adaptation to sudden environmental changes.

For a human point of view, biofilms can be beneficial or detrimental. Biofilms are utilized in water purification and bioremediation of hazardous substances in the environment. However, they cause inconvenience when formed on industrial surfaces or when causing persistent infections in humans, animals, or plants.

Biofouling is a term describing unwanted biofilm formation on equipment surfaces. This can occur in wide range of manmade environments and can significantly decrease equipment performance and lifetime and cause contamination and impaired quality of the products. Because biofilms are more resistant against external forces than free swimming cells, they are more difficult to eradicate from industrial processes by biocides or cleaning agents. Therefore, they create diverse problems. In the food industry, biofilms may provide a habitat for many pathogenic bacteria and are common sources of contamination. Because biofilms are attached and grow on the surfaces of food-processing equipment, other food contact surfaces, and pipelines, they are not always removed by routine cleaning procedures. This may lead to serious hygienic problems and food spoilage.

Pathogens in Biofilms

Microbes inhabiting contact and environmental sites in food processing are mainly harmful, as attached microbial

 doi:10.1016/B978-0-12-378612-8.00361-9

communities lead to contamination of surfaces and the product produced in the process. However, it is even more alarming to know that pathogens such as *Escherichia coli* O157:H7, *Listeria monocytogenes*, *Salmonella* Typhimurium, *Campylobacter jejuni*, and *Yersinia enterocolitica* can easily produce biofilms or be a part of biofilm communities. According to the literature survey, all the common pathogens are reported to be detected on food process surfaces. Specific properties of pathogens in biofilms have been studied in laboratory studies and, for instance, it has been found that biofilm cells of *Listeria* are more resistant than planktonic cells to disinfectants containing, for example, chlorine, iodine, quaternary ammonium, and anionic acid compounds.

Pathogen contamination can be defined as prolonged or persistent contamination when a strain has caused food plant contamination for long periods of up to several years. Persistent *Listeria* strains have been reported in several food industry areas, for example, meat, poultry, fish, dairy, and fresh sauces. *Escherichia coli* and *Salmonella* isolates are also known to be persistent in food and fish-feed factories. Persistent plant contamination can be caused by properties that influence survival, including enhanced adherence to food contact surfaces and adaptation to disinfectants, in addition to such predisposing factors in the processing line as complex processing machines and poor zoning.

Biofilm Detection

In assessing hygiene, it is essential to detect the microbes remaining on surfaces after cleaning. Hygiene assessment includes checking the amount of surface-attached soil including protein, polysaccharide, other organic and inorganic residues, biofilm, dead and/or living microbes in general, or specific pathogens and other harmful microbes. Hygiene assessment also helps with tracing contamination sources and in optimizing cleaning systems. The sources of microbial contaminants in the final product can be several: raw materials, process equipment, environmental surfaces, air, animals, and personnel. Quantification of the actual number of microbes from surfaces is challenging. Detection methods for measuring microbes directly from the surface are rare and unpractical for field use (i.e., microscopy) and detachment of microbes completely without damaging the surface or the microbes is difficult due to strong microbial adherence of biofilms. The traditional detachment method is swabbing not only with cotton-tipped swab but also other sterile swabs, sponges, and nonwoven cloths can be used as well as ultrasonication. The disadvantage of culturing-based methods is long incubation periods since results are needed immediately. Microscopy is very often used as a reference method for swabbing and culturing (Figure 1). It has been reported that the cells counted by direct microscopy consistently give results one log unit higher than the culturing methods. Epifluorescence microscopy has clearly revealed that with swabbing only a small part of the biofilm is detached. To detach surface-adherent cells, using excessive agitation and strong chemicals may harm the cells, thus, making them unable to grow in the culturing procedure. Surfaces can be tested using contact agar methods by pressing relevant nutrient agar against the surface for few seconds. According to a collaborative study for validation of total aerobic bacterial and enterobacterial count using Hygicult® dipslides (commercial contact agar application), contact agar dishes and swabbing revealed that 15–20% of the theoretical yield of contaminants on artificially soiled stainless-steel surfaces were detected with all used methods. Adenosine triphosphate bioluminescence and protein detection kits can provide a real-time estimation of overall cleaning efficacy of organic soil or protein residues respectively. However, these methods are unable to detect the presence of low numbers of bacteria on surfaces where other organic soil is not present. Visual observation of cleanliness is also recommended in many cases. Visual observation can be improved by using test foam, which contains dyeing agents that attach selectively to the protective matrix of most biofilms commonly found in food industry or by using ultraviolet-lamp, which makes some organic soil fluorescent, or by wiping the surface with white tissue.

Microbial biofilms can be detected and quantified using microscopy techniques like fluorescence or scanning electron microscopy (Figure 2) in combination with appropriate software for image analysis. Also, by microscopy it is possible to distinguish different components of biofilms (microorganisms, protein, and carbohydrates) by specific dyes/probes. However, microscopy requires samples that can be easily transported to laboratory and is not always suitable to field conditions.

Real-time polymerase chain reaction (PCR), also called quantitative real-time PCR (qPCR), is a technique which is used to amplify and simultaneously quantify a targeted deoxyribonucleic acid (DNA) molecule. The procedure for qPCR follows the general principle of PCR excepting that the amplified DNA is detected as the reaction progresses. The methods for detection of amplification products are using a double-stranded DNA-specific fluorescent dyes or sequence-specific DNA probes consisting of oligonucleotides that are labeled with a fluorescent reporter, which permits detection only after hybridization of the probe with its complementary DNA target. The qPCR method can be used for detection and quantification of bacterial species forming a biofilm. This method being very sensitive might be useful in food industry, where excluding the presence of certain pathogenic species is important.

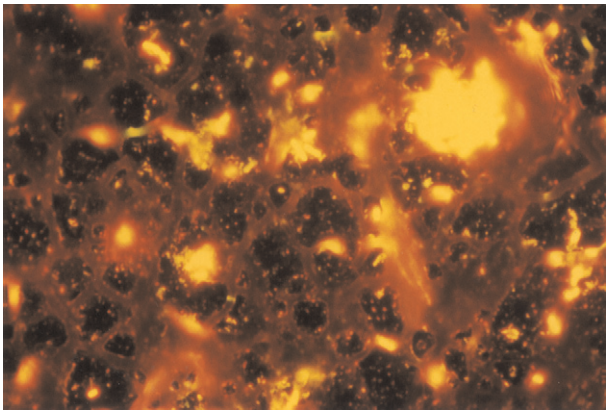

Figure 1 Biofilm on stainless-steel surface, which is stained with acridine orange and observed using epifluorescence microscopy. Bright orange rods and clumps are microbe cells and the clouded orange net is extracellular matrix (slime produced by microbes).

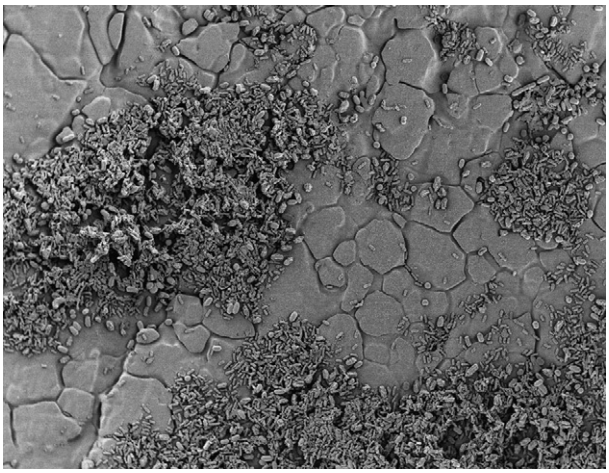

Figure 2 Scanning electron micrograph of bacterial biofilm on stainless steel.

Biofilm Prevention

Hygienic Design

The hygienic design of process equipment has a significant impact on reducing the risks of contamination of food during production. Poorly designed equipment which is difficult to clean, can harbor spoilage microbes and pathogens. This can be avoided through hygienic equipment design, which should be taken into consideration when purchasing new or redesigning old process lines. The basic rule in hygienic design is to use simple structure which is stated in most common guidelines. The process equipment is easy to clean if the surface materials are smooth and in good condition. Dead ends, corners, cracks, crevices, gaskets, valves, and joints are vulnerable points for biofilm accumulation. Equipment that causes problems in food processing and packaging include slicing and cutting equipment, filling and packing machines, conveyors, plate heat exchangers, and tanks with piping. These types of equipment can cause contamination through spoilage microbes and pathogens as they are difficult to clean, for example, the pathogen *L. monocytogenes* is often associated with harborage in poorly designed equipment.

The European Commission Regulations 852/2004, 853/2004, and 854/2004 cover the principal objective of the new general and specific hygiene rules to ensure a high level of consumer protection with regard to food safety. Legislative demands set the basic requirements for the manufacturing of safe food products, whereas food safety management systems and food safety guidelines and standards based on given legislation help the food industry to keep up with the current food safety requirements. Hygienic requirements should be adopted at the initial stage of developing process equipment and components because upgrading existing designs to meet hygienic requirements is often both expensive and unsuccessful. Legislation states that strict requirements regarding technical specifications for hygienic designs, constructions, and installations of process equipment are needed. It is important for process equipment manufacturers to have their design or prototype tested to the given requirements. European Hygienic Engineering and Design Group (EHEDG) has developed an evaluation and certification program in which certified equipment and components have been evaluated and tested according to relevant design criteria and legislation available, for example, the EHEDG document no. 8 (1993) on design criteria for hygienic equipment. This guarantees that the equipment is of a good hygienic design and is easy to clean. There is also a need for criteria and procedures for testing, assessment, and certification of such process equipment such that the formal mark guarantees that the equipment functions in conformity with predefined requirements.

The cleanability results can be used for optimizing the cleaning parameters and plant design. Simulations obtained using computational fluid dynamics (CFD) can be used to relate information on cleaning efficiency to the physical design of processes. CFD is used in many applications to model the bulk parameters of fluid flows. Recently model developments have made it possible to resolve local flow phenomena in specific positions and near walls, which is of interest in the study of cleaning processes. Results of the CFD simulations yield information about wall shear stresses and the flow rates in different parts of the system. A combination of wall shear stress, fluid exchange, and turbulence conditions can be used to predict areas that are not properly cleaned in both simple and complex flow systems.

Cleaning Procedures

It is important to address the cleaning procedures in food industries due to economics, efficacy, and safety issues. The cleaning procedure of food-processing factories may occasionally need to be improved, for example, if pathogens have been detected on process surfaces. Improvement of regular cleaning programs may also be needed in order to improve the quality and safety of the product. Once developed, biofilms are difficult to remove completely. Moreover, increased resistance to chemicals will occur due to changes in physiology when microbes are attached on the surfaces. It is not sufficient to kill the microbes; the remaining matrix must also be removed, because it provides an excellent opportunity for rapid reestablishment of new biofouling. Parameters effecting the cleaning of surfaces are chemical agents, mechanical forces, temperature, and duration of the cleaning procedure. The selection of detergents and disinfectants in the food industry depends on the efficacy, safety, and rinsability of the agent as well as where it is corrosive or affects the sensory values of the products manufactured. Disinfectants allowed for use in food factories also needs to be accepted by authorities. The European Union (EU) biocide directive states procedure for acceptable disinfectants and keeps record on accepted disinfectants. The key to effective cleaning and disinfection of food plants lies in the understanding of the type and nature of the soil (sugar, fat, protein, mineral salts, etc.) and the microbial contamination on the surface. In a wet open process, the gross soil should be removed by dry methods, for example, brushing, scraping, or vacuuming and visible soil rinsed off with low-pressure water. Disinfectants approved for use in the food industry are alcohols, chlorine-based compounds, quaternary ammonium compounds, oxidants

(peracetic acid, hydrogen peroxide, and ozone), persulphates, surfactants, and iodophors (the new registration of disinfectants according to EU biocide directive is in active state at the time this list is written).

Biofilm Management

Wet industrial processes provide environments for formation of microbial biofilms because open processes are impossible to keep sterile. In processes like food manufacturing, control of biofouling with chemical biocides is not possible. Engineering surfaces and coating materials to repel microbial adhesion or using physical methods (e.g., photocatalysis, electrochemical, and polarization) rather than chemicals, is therefore of great interest for antifouling. However, designing materials or coatings effectively repelling toward all kinds of microbial colonization on long-term basis has proven to be impossible. The countermeasures against biofouling should be separately tailored for each individual process situation.

Systematically operated process line ensures optimal runability. One way to ensure high performance is to implement hazard analysis and critical control points (CCPs) and good manufacturing practices (GMPs), which primarily deal with hygiene, cleaning, and CCP monitoring. The commitment from the management and motivated personnel is essential in order to benefit from these quality systems.

Processes or products can be protected from contaminants in the air by operating in the cleanroom. Cleanroom is defined as a room in which the concentration of airborne particles is controlled, and which is constructed and used in a manner to minimize the introduction, generation, and retention of particles inside the room, and in which other relevant parameters, for example, temperature, humidity, and pressure, are controlled as necessary. The cleanroom class needed should be chosen according to the process step and the processed product. Packaging step in food processing is a typical process step in which cleanroom technology can be applied. The shelf life of product increases when the product is packed correctly in a controlled room. It is important to follow the GMP rules about clothing and behavior, especially when working in cleanroom. Basic standards for designing cleanrooms and associated controlled environments are standard series ISO 14698 on biocontamination control and ISO 14644 dealing with topics such as general principles and methods; evaluation and interpretation of biocontamination data; classification of air cleanliness; specifications for testing and monitoring; test methods; design, construction, and start-up; operations; vocabulary; separative devices (clean air hoods, glove boxes, isolators, and minienvironments); classification of airborne molecular contamination; and classification of surface particle cleanliness.

Glossary

Analytical unit The actual volume/mass/area etc., of a sample unit that is tested in the specified method: An analytical unit may comprise the entire sample unit, or may be an aliquot of the sample unit.

Food safety objective (FSO) A metric advocated by Codex Alimentarius and established by a competent authority that represents the maximum level of a hazard in a food at the point of consumption that may be tolerated in the light of an appropriate level of (health) protection (ALOP) or relevant policy decisions on public health protection.

Guideline An advisory criterion that may be established by regulators, industry, or trade associations that articulates expected quality and/or safety when best practices are applied to the manufacture of the food.

Homogeneous Uniformly distributed, for example, when referring to the characteristic of the distribution of microorganisms in the lot.

Lot A specified quantity of some commodity manufactured or produced under conditions which are presumed to be, or have been, uniform for the purpose of application of sampling plans.

Microbiological criterion A statement or specification that defines the acceptability of a product or a food lot, based on the absence or presence, or number of specified microorganisms including parasites, and/or quantity of their toxins/metabolites, per unit(s) of mass, volume, area, or lot. Complete specification of a microbiological criterion includes definition of n (the number of sample units taken), m (the microbiological limit for any individual sample units), c (the maximum number of analytical units (*q.v.*) in the sample that are permitted to not comply with the attribute m) and, for a three class plan, M (a limit that if exceeded in any analytical unit in the sample renders the entire lot unacceptable), as well as: Statement of the microorganism(s) of concern and/or their toxins/metabolites and the reason for that concern; the food to which the criterion applies; the specific point(s) in the food chain to which the criterion applies; the analytical methods to be used and any actions to be taken when the criterion is not met.

Operating characteristic (OC) curve A graph that relates the probability of acceptance of a lot as a function of its actual quality (rate of defects or concentration level). The shape of the curve depends on the stringency of the sampling plan (number of sample units n, number of positive sample units acceptable c).

Sample One or several units, or portions, of the material comprising the lot.

Sampling plan A specification of the number and size of samples to be taken from a lot, and the method of testing in order to obtain information needed to decide whether that lot complies with some particular criteria for microbiological quality or safety; a sampling plan is part of a microbiological criterion.

Specification A microbiological criterion which is applied as a condition of acceptance of a food or ingredient by a food manufacturer or public, or private agency;
it can be mandatory in a supplier–buyer relationship.

Standard A microbiological criterion which is part of a law or regulation (a mandatory criterion enforceable by the regulatory agency having jurisdiction).

Microbiological Testing

Microbiological testing is frequently used to determine the microbiological quality and safety of foods. The results of such testing are sometimes (incorrectly) interpreted as absolute, but due to simple statistical effects and generally substantial heterogeneity in the distribution of microorganisms in food, the results should definitely not be considered as such. In many cases, the number of samples required to prove a certain absolute level of control is impractically large.

Nevertheless, microbiological testing generally is an important part of a food safety management system. For instance, in the import and export of shipments for which no information is available on the food safety management system used in the production of a food, no other means of food safety assessment is possible. For food safety management systems in which the control of food safety is assured by other

 doi:10.1016/B978-0-12-378612-8.00363-2

means, like the application of best practices and Hazard analysis and critical control points (HACCP) principles, microbiological testing is key for verification purposes. Microbiological testing can also be usefully applied for other purposes (in many different contexts, see Table 1) and at various locations in the food chain (Table 2).

Depending on the specific purpose for testing (e.g., specific batch testing, verification, and investigational sampling) of the food and food production situation under consideration, the expected variability in results, frequency of sampling, the numbers of samples to be taken, and the specific limits to test against will vary.

Finished product:
Verify effectiveness of HACCP, GHP programmes
Verify compliance of lot against regulatory standards
Verify compliance of lot to agreed specifications
Port-of-entry assessments in import/export

Microbiological Criteria

A microbiological criterion includes a number of elements that together establish the microbiological acceptability of a product for a specific purpose, whether as an ingredient in a particular food product or for a final food product intended for consumption with or without particular preparation. In establishing whether a final food product is microbiologically acceptable, therefore, the expected further handling and treatment of the food is an important consideration. Microbiological testing is carried out against a sampling plan specified in a microbiological criterion by the limit or limits to the level of a particular microorganism for each analytical unit and the proportion of the analytical units representing the batch or lot that must be below the microbiological limit(s).

According to Codex Alimentarius, microbiological criteria define the acceptability of a product or a food lot, based on the absence or presence, or number of microorganisms, per unit(s) of mass, volume, area, or lot. They should specify all the following elements:

- The food and the point(s) in the food chain where the criterion applies;
- Any actions to be taken when the criterion is not met;
- A statement of the microorganism(s) of concern;
- A plan defining the number of field samples to be taken;
- The size of the analytical unit to be tested for each field sample;
- The analytical method(s) for detection/quantification;
- Microbiological limit(s) considered appropriate to the number of microorganisms found in the analytical units; and
- The proportion of analytical units that should conform to the(se) limit(s).

The last five elements together form the sampling plan underlying a microbiological criterion. The sampling plan is a key part of the microbiological criterion as it determines the stringency of microbiological acceptability. So far, the performance of sampling plans has not been a required element of a microbiological criterion as defined by Codex, but in the ongoing revision of the Codex guidelines on establishing microbiological criteria, this additional element may be considered.

Microbiological criteria may have different standings in different contexts. A standard is a microbiological criterion which is part of a law or regulation; it is a mandatory criterion that is legally enforceable by the regulatory agency having jurisdiction. A guideline is an advisory criterion that may be established by regulators, industry, or trade associations to articulate microbiological levels that are achievable when best practices are applied to the production or manufacture of foods, whereas a specification is a microbiological criterion that is applied as a condition of acceptance of a food or ingredient by a food manufacturer or public, or private agency. A specification can be mandatory in a supplier–buyer relationship.

Two types of sampling plans can be distinguished, attribute plans and variable plans. In attribute plans experimental results are attributed to certain classes (desirable, marginal, and/or unacceptable). In variable plans all quantitative results of

the test are quantitatively used in the criterion. The focus here is on attribute plans.

Two- and Three-Class Sampling Plans

The International Commission on Microbiological Specifications for Foods (ICMSF) defined 15 risk categories ('cases'; see Table 3) that differentiate acceptable levels of microorganisms in foods based on the degree of health risk possibly posed by food containing specific microorganisms as dictated by: (1) the inherent severity of infection by the pathogen or ingestion of a microbial toxin, (2) the conditions of handling and use of the foods, and (3) the susceptibility to foodborne illness of the population intended to consume the food. These cases use different sampling plans to reflect the stringency required for microbiological acceptance. For lower degrees of risks, 'three class' sampling plans are advocated, although 'two class' sampling plans are more usual for higher degrees of risk. Three class plans are used where some tolerance of the presence of the specific microorganism is acceptable and does not present a risk to consumers. In three class plans, 'm' represents the desirable level that is consistent with a product of good microbiological acceptability. Recognizing that deviations may occur in food production, some margin of tolerance is allowed. However, there is a second limit in three class plans that should never be exceeded as this would mean that the product is unacceptable. This intolerable level is defined by 'M.' In two class plans, there is only one limit, 'm,' which renders the unit nonconforming when exceeded. Usually, three class plans are used where higher levels of the target organism are acceptable and quantitative methods are used, whereas two class plans are more commonly used when only very low levels of microorganisms are tolerated and qualitative ('presence/absence') methods are used.

Thus, whereas both kinds of sampling plans specify the methodology, the number of analytical units, microbiological limits, and the proportion of analytical units that must satisfy the microbiological limit(s), three class plans additionally specify desirable levels, completely unacceptable levels and, by inference, marginally acceptable levels.

In Figure 1, both types of sampling plans are illustrated. The x-axis shows increasing concentrations of microorganisms that could occur in the food product. The y-axis shows the likelihood of a particular concentration occurring. The curve in the graphs shows a lognormal distribution of the concentration of microorganisms. This kind of distribution is often assumed to reflect natural variation or heterogeneity. The curve shows that concentrations of 2.8 log cfu g^{-1} are most likely to occur, whereas concentrations at the lower end of the scale, for example, 1 log cfu g^{-1}, or at the higher end of the scale, i.e., 5 log cfu g^{-1}, are much less likely to occur. In both graphs, an indication is given of the proportion of concentrations that, when found, would indicate that the unit is nonconforming (i.e., often meaning the lot being qualified as defective); for three class plans, also the proportion is shown that would be in the marginally acceptable range.

Characteristic Numbers Defining a Sampling Plan

The characteristic numbers for a two class sampling plan are the number of analytical units to sample (n), the microbiological limit (m) that determines the acceptability of each of the analytical units, and the number of analytical units (c) that are allowed not to meet the limit. A three class plan specifies the number of analytical units to be sampled (n), a lower microbiological limit defining acceptable analytical units (m), an upper microbiological limit defining completely unacceptable analytical units (M), thereby defining the defective lots, and the number of analytical units (c) that are allowed to be in the 'marginal' range, thus between 'm' and 'M.' In a three class plan, a lot or batch can be rejected if too many ($>c$) of the sampled analytical units are found to be in the marginal range, or if any of the analytical units exceeds 'M.' It is desirable that the values selected for m and M are not too close together for the analytical method to be able to discriminate between them.

Microbiological criteria should be defined only where there is a need to articulate criteria for microbiological acceptability, whether for reasons of trade or public health. Next to the sampling plan details discussed above, they should clearly state or describe all characteristic elements defining the

Table 3 Cases for sampling plans as described by ICMSF

Hazard/microorganism	*Effect on risk due to conditions in which the food is expected to be handled after sampling*		
	Reduction of risk	*No change in risk*	*Increase of risk*
Utility	Case 1 Three class, $n=5$, $c=3$	Case 2 Three class, $n=5$, $c=2$	Case 3 Three class, $n=5$, $c=1$
Indicator	Case 4 Three class, $n=5$, $c=3$	Case 5 Three class, $n=5$, $c=2$	Case 6 Three class, $n=5$, $c=1$
Moderate hazard	Case 7 Three class, $n=5$, $c=2$	Case 8 Three class, $n=5$, $c=1$	Case 9 Three class, $n=10$, $c=1$
Serious hazard	Case 10 Two class, $n=5$, $c=0$	Case 11 Two class, $n=10$, $c=0$	Case 12 Two class, $n=20$, $c=0$
Severe hazard	Case 13 Two class, $n=15$, $c=0$	Case 14 Two class, $n=30$, $c=0$	Case 15 Two class, $n=60$, $c=0$

criterion. These include the microorganism targeted, the point in the food supply chain it applies, the analytical method advised and actions taken regarding defective lots/batches. Microbiological criteria should also include the field sample size, particularly for presence/absence of testing.

Sampling Plan Cases

To select values for *n* and *c*, the risk categories ('cases') as defined by the ICMSF (Table 3) can be used as guidelines, as these clearly are taking into account the degree of concern of the hazard and the conditions of storage and use.

The cases in Table 3 differentiate between different types of hazards and microorganisms. Utility organisms are measures of general contamination not directly related to safety, like total plate count, cold tolerant organisms, and lactic acid bacteria. Indicator microorganisms, like Enterobacteriaceae or coliforms, usually are not directly harmful, but may indicate the likely presence of pathogens. Moderate hazards cause illness symptoms of short duration, which are rarely life threatening, and do not result in serious sequelae (e.g., *Bacillus cereus*, *Staphylococcus aureus*). Serious hazards result in disease of moderate duration and do not normally result in sequelae (e.g., *Salmonella enteritidis*, hepatitis A). Severe hazards can result in substantial chronic sequelae or effects that can be of long duration (e.g., *botulinum* toxin, enterohemorrhagic

Escherichia coli). Notably, hazards that are termed moderate for the general population may be serious hazards for particularly sensitive subgroups (e.g., *Salmonella* in infant food).

Going from case 1 to 15, the level of public health concern increases, as it also increases going from the lower case to the higher case per row or from the first to the last row in the table. For each case, a sampling plan type and typical characteristic numbers for the sampling plans are proposed to give guidance on the level of stringency that could be applied for lot acceptance. However, suitable microbiological limits, and the appropriate size of the analytical units need to be established for each case additionally according to the required performance of the sampling plan for the specific purpose that the microbiological criterion is established.

Performance of Sampling Plans

Although the ICMSF cases have proven useful as general guidance, the specific number of samples, the proportion of compliant analytical units, the microbiological limits and the size of analytical units proposed cannot be directly related to public health risk. Therefore, the approach has been taken further by determining the performance of sampling plans in greater detail. Depending on the level of heterogeneity expected (i.e., as characterized by the standard deviation of the assumed log normal distribution of counts of bacteria within the lot) the average level of contamination that can be detected with a specified level of certainty (or 'confidence') can be determined. The decisions to be taken on the basis of assumptions or additional data generation for the specific situation are much the responsibility of risk managers, aided with data brought forward by risk assessors. In particular, the actual standard deviation of contamination levels within the batch would be essential as well as the target level of contamination tolerated for microbiological acceptability linked to the feasibility to detect such a level. Guidance here can be obtained from recent studies on the actual distribution of microorganisms in foods and how best to model these.

Example of Different Aspects of a Sampling Plan

The application of microbiological criteria with full specification of all elements, such as the underlying sampling plan, as advisory standards for the control of relevant microorganisms, is clearly exemplified in the recently published Codex criteria for powdered formulae for infants and young children, as shown in the following textboxes.

In Textbox 1 the sampling plans are defined for *Cronobacter* and *Salmonella* as these two microorganisms are considered significant pathogens that need to be controlled. In each sampling plan, the number of sample units (n) to be tested and the analytical unit (10 or 25 g) are specified. Because both organisms are considered capable of causing severe disease for the highest risk-group within the intended population (i.e., new borne infants), a two class plan is used and no sample units are permitted to be positive ($c=0$). In effect, this sampling plan requires absence in 10 g in each of the 30 sample units taken for *Cronobacter* and absence in 25 g for *Salmonella* in each of 60 sample units taken.

Although not currently a requirement for microbiological criteria, the performance of the sampling plans is also specified for both microorganisms, which depends on the standard deviation for the distribution of the microbial cells in the food lot and the probability of detection of defective lots selected (Textbox 2). The sampling plan performance is expressed as the sensitivity of detection giving the selected standard deviation and probability of detection.

The analytical methods deemed most appropriate for detection of the two different microorganisms are duly described and criteria for the selection of alternative methods are provided (Textbox 3), as is the stage in the food chain where the microbiological criteria apply (Textbox 4), and the action to be taken when products are found not to conform to the sampling plan (Textbox 5).

Textbox 1 Definition of a sampling plan for powdered formulae for infants and young children

Microorganisms	*n*	*c*	*m*	*Class plan*
Enterobacter sakazakii (*Cronobacter* species)*	30	0	0/10 g	2
*Salmonella***	60	0	0/25 g	2

Where n=number of samples that must conform to the criteria: c=the maximum allowable number of defective sample units in a two class plan. m=a microbiological limit which, in a two class plan, separates good quality from defective quality.

Textbox 2 Performance of the sampling plan for *Cronobacter* and *Salmonella*

*The mean concentration detected is 1 cfu in 340 g (if the assumed standard deviation is 0.8 and probability of detection is 95%) or 1 cfu in 100 g (if the assumed standard deviation is 0.5 and probability of detection is 99%).

**The mean concentration detected is 1 cfu in 526 g (if the assumed standard deviation is 0.8 and probability of detection is 95%).

Textbox 3 Description of the methods to be used

The methods to be employed for *E. sakazakii* (*Cronobacter* species) and *Salmonella* should be the most recent editions of ISO/TS 22964: 2006 and ISO 6579, respectively, or other validated methods that provide equivalent sensitivity, reproducibility, reliability, etc.

Textbox 4 Locations where the criteria apply

These are to be applied to the finished product (powder form) after primary packaging or anytime thereafter, up to the moment when the primary package is opened.

These Codex guidelines furthermore define process hygiene criteria to determine the quality of the manufacturing conditions under which the product is produced (Textbox 6). These criteria target two groups of microorganisms (i.e., Mesophilic aerobic bacteria and Enterobacteriaceae) that themselves do not necessarily pose a risk to consumers, but that are utility microorganisms, or possibly indicate the presence of harmful microorganisms due to insufficient conditions of general hygiene in the operation. When product lots do not comply with these hygiene criteria, it signals a high probability that the manufacturing operation is not under sufficient control and appropriate action needs to be taken by the manufacturer to improve the situation before new food lots are produced. Also when food lots are found to be of marginally acceptable quality, the manufacturer should consider appropriate action, such as investigating the hygienic conditions in place and more tightly monitoring food lot quality parameters as to avoid production of defective lots.

A three class plan is used for the 'utility' microorganisms (mesophilic aerobic bacteria) with $n=5$ samples, of which none should be above $M=5000\ g^{-1}$, with no more than two sample units between $m=500\ g^{-1}$ and $M=5000\ g^{-1}$. An exception for this criterion is made, of course, for microorganisms that are intentionally added such as probiotics (explained in the footnote '∗' in the criteria). For the indicator microorganisms (Enterobacteriaceae), a two class plan with $n=10$ samples is defined, of which maximally two sample units can be found positive in a 10 g enrichment. Although for other foods it is more common to use a three class plan approach for indicator microorganisms, in the case of powdered formulae for infants and young children a two class plan is defined due because only very low levels of Enterobacteriaceae are typically occurring when stringent hygiene conditions are maintained.

The performance of this plan for detecting Enterobacteriaceae is described in Textbox 7.

The appropriate methods for analysis are given in Textbox 8.

The locations and scope of use of these microbiological criteria are articulated in Textbox 9 and the action to be taken when samples are found not to conform to the process hygiene criteria (Textbox 10).

Statistical Aspects

Microbiological criteria are used as a tool that is powerful enough to detect defective food products but limits the level of sampling and testing required for this. The level of testing relates much to the statistical aspects of sampling and testing. The first important aspect to realize is that there is a clear distinction between the power of one test ($n=1$), and the result of a sampling plan with a certain n and c value. A single test of a relatively small sample of a food lot or batch obviously would not give much assurance of product safety, considering that lot sizes in a manufacturing operation are very large (e.g., from hundreds of kilograms upward to hundreds of

Textbox 5 Description of the actions to be taken if the product is not conform

The typical action to be taken when there is a failure to meet the above criteria would be to: (1) prevent the affected lot from being released for human consumption, (2) recall the product if it has been released for human consumption, and (3) determine and correct the root cause of the failure.

Textbox 6 Process hygiene criteria

Microorganisms	*n*	*c*	*m*	*M*	*Class plan*
Mesophilic aerobic Bacteria*	5	2	$500\ g^{-1}$	$5000\ g^{-1}$	3
Enterobacteriaceae**	10	2	0/10 g	Not applicable	2

Where n=number of samples that must conform to the criteria: c=the maximum allowable number of defective sample units in a two class plan or marginally acceptable sample units in a three class plan: m=a microbiological limit which, in a two class plan, separates good quality from defective quality or, in a three class plan, separates good quality from marginally acceptable quality: M=a microbiological limit which, in a three class plan, separates marginally acceptable quality from defective quality.

Textbox 7 Performance of Enterobacteriaceae hygiene criteria

**The mean concentration detected is 1 cfu in 16 g (if the assumed standard deviation is 0.8 and probability of detection is 95%) or 1 cfu in 10 g (if the assumed standard deviation is 0.5 and probability of detection is 99%).

Textbox 8 Description of the methods for process hygiene criteria

The methods to be employed for mesophilic aerobic bacteria and Enterobacteriaceae should be the most recent editions of ISO 4833: 2003 and ISO 21528–1/21528–2, respectively, or other validated methods that provide equivalent sensitivity, reproducibility, reliability, etc.

Textbox 9 Description of point of application and scope of process hygiene criteria

These are to be applied to the finished product (powder form) or at any other previous point that provides the information necessary for the purpose of the verification.

The safe production of these products is dependent on maintaining a high level of hygienic control. The following additional microbiological criteria are intended to be used by the manufacturer as a means of ongoing assessment of their hygiene programs, and not by the competent authority. As such these tests are not intended to be used for assessing the safety of a specific lot of product, but instead are intended to be used for verification of the hygiene programs.

tons). To ensure safety of the product only by testing, every part of a lot would have to be tested and no product would be left to sell. Importantly, when a safe product and process design are implemented in a food production operation that is managed with proper hygienic practices and an adequate HACCP principles approach, sampling and testing serves much more the purpose of verifying whether the operation is in control and thus the product is safe. Even for batches for which the management is not known, such as port-of-entry situations, a somewhat limited amount of sampling and testing can give sufficient confidence that the product was produced under appropriate conditions. However, good knowledge of the statistical aspects of sampling and testing is essential to determine what limited level is sufficient for food safety assurance through the use of microbiological criteria.

Acceptance of the Batch Following a Certain Sampling Plan

The curve representing the probability of accepting a batch based on the n and c value as function of the proportion defective sample units is named the operating characteristic curve (OC-curve).

This probability can be described as a Binomial distribution:

$$P_{\text{accept}}(n,c,P_{\text{defective}}) = \text{Bionomial}\ (k \leq c, n = n,\ P = P_{\text{defective}})$$

Determining the cumulative probability of all possible numeric outcomes k, smaller than or equal to the c-value given the probability to be defective ($P_{\text{defective}}$) per sample unit and the number of sample units (n).

Textbox 10 Description of the actions to be taken if the samples are not conform with the process hygiene criteria

The typical action to be taken when there is a failure to meet the above criteria would be to determine and correct the root cause of the failure and, as appropriate, review monitoring procedures, environmental surveillance, and review prerequisite programs in particular the hygienic conditions from the drying step up to the packaging step (Enterobacteriaceae) and the process conditions during wet processing (mesophilic aerobes). Continued failures should be accompanied by increased sampling of the product for *E. sakazakii* (*Cronobacter* species) and *Salmonella* and potential revalidation of the control measures.

For sampling plans in which $c=0$, as is often used for pathogens, this equation equals:

$$P_{\text{accept}}(n,c,P_{\text{defective}}) = \text{Binomial}\ (k = 0, n = n,\ P = P_{\text{defective}})$$

$$= (1 - P_{\text{defective}})^n$$

From this equation it can be clearly shown that the performance of sampling is often rather poor even when high numbers of samples are tested, if the sampling is required to be able to detect a low rate of defective (i.e., contaminated) products (Table 4), which generally should be the case for pathogens which would be occurring infrequently and at low concentration.

From Table 4 it can be seen that even a sampling plan with 60 sample units has quite a low probability of detecting contamination rates of 1% or 2% as the probabilities of acceptance are still 55% and 30%, respectively. To put this in to a practical example: In a batch of 100 000 chocolate bars of which 1% are contaminated with *Salmonella*, i.e., 1000 bars, the probability that this rate of contamination would be detected with 60 sample units is only 45%, meaning that such a batch will go undetected in 55% of the cases. Obviously, in practice, *Salmonella* contamination rates of 1% or 2% in chocolate would already be rather high. Also, the statistics presented in Table 4 assume that the contamination is homogenously distributed throughout the batch, and that $P_{\text{defective}}$ is equal for every sample unit taken. If the contamination however is heterogeneously distributed, $P_{\text{defective}}$ is not equal for every sample taken and there will be an impact on the underlying statistics. This is discussed in the Section 'Probability that a Sample Unit is Defective or Conform'.

When sampling plans are compared and their stringency in making decisions is considered, such as in the examples given in the Section Example of Different Aspects of a Sampling Plan, different aspects of their performance can be addressed. In the ideal situation, the OC curve would switch from a 100% probability of acceptance to a 100% probability of rejection just at the limit of the proportion defective that distinguishes between conforming and nonconforming lots. In practice, as in the previous examples, it is unlikely that a sampling plan can achieve this ideal, but the steeper the curve, the closer the sampling plan comes to approaching the ideal. In general, steeper curves can only be achieved by increasing the number of sample units n to be drawn from a lot. Also a lower value for the acceptance number c will result in a general reduction of the failure to reject a noncompliant lot (i.e., the consumer's risk). From a consumer's or a regulator's point of view, the

Table 4 Probability of accepting a lot with a specified rate of nonconforming units (i.e., $P_{\text{defective}}$) depending on the numbers of sample units analyzed (n), and when no sample unit is permitted to be positive ($c=0$)

% Defective samples ($P_{defective}$)	n = 1	n = 2	n = 5	n = 10	n = 15	n = 20	n = 30	n = 60
0 (0.00)	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
1 (0.01)	0.99	0.98	0.95	0.90	0.86	0.82	0.74	0.55

confidence in ensuring food safety by applying a sampling plan will tend to focus on a rejection of noncompliant lots with high probability, for example, 95% (or accepted with low probability). Food producers, however, will be more interested in examining which lot quality would be accepted with high probability, say 95%, to adjust their production processes accordingly. This is explained in more detail elsewhere.

Probability that a Sample Unit is Defective or Conform

A second aspect to consider is the probability that any sample unit is either defective or compliant with the microbiological limit. For determining this, the (statistical) distribution of the contaminant in the batch should be known. If the contamination is homogeneously distributed due to complete mixing, the probability that a sample unit is positive is equal for every sample. But if the contamination is heterogeneous, $P_{\text{defective}}$ can be different for every sample and is in itself statistically 'distributed'. Often it is assumed that the contaminants are lognormally distributed. Also other distributions can be assumed or found to be preferable, but due to the fact that many microbial processes are of exponential nature, the assumption that a log transformation makes the distribution normal is reasonable.

Two situations have to be distinguished, first the use of an attribute plan with a given quantitative value of the *m*-value. In this case, the probability that a sample unit is defective equals:

$$P_{\text{defective}} = P_{\text{normal}}\,(\log C > m,\ \text{mean}_{\log C},\ \sigma_{\log C})$$
$$= 1 - P_{\text{normal}}\,(\log C \le m,\ \text{mean}_{\log C},\ \sigma_{\log C})$$

In the case an absence/presence test is carried out (e.g., for two class plans), the probability can be determined by:

$$P_{\text{defective}} = \int_{-\infty}^{\infty} P_{\text{normal}}\,(\log C,\ \text{mean}_{\log C},\ \sigma_{\log C}) \times (1 - \exp\,(-C \times \text{samplesize}))\ \text{d}\log C$$

(In this case the *m* value can be seen as *m* = absence in sample size grams).

Based on the mean log concentration (geometric mean, so the mean on log scale) and the standard deviation (and for counts the *m* value and for enrichments the sample size) $P_{\text{defective}}$ can be determined and can be used to determine the overall performance of the sample plan (based on *n* and *c*) as described in Section Acceptance of the batch following a certain sampling plan. This whole process is exemplified in Figure 2. In this manner the OC-curve is presented as a function of the quality of the batch defined as mean log concentration, having a better relation with risk than the proportion defective samples, because this proportion depends also on factors like the size of the analytical unit.

Difference between a Microbiological Criterion and an FSO/PO

A food safety objective (FSO) specifies the maximum permissible level of a microbiological hazard in a food commodity at the moment of consumption and is based on a management decision regarding the acceptable risk of the hazard to the population or on a public health goal. Maximum hazard levels at other points along the food chain are called performance objectives (POs) and can be derived from the FSO. The current definitions for FSO and PO are that an FSO is: 'the maximum frequency and/or concentration of a hazard in a food at the time of consumption that provides or contributes to the appropriate level of (health) protection (ALOP),' whereas a PO is: 'the maximum frequency and/or concentration of a hazard in a food at a specified step in the food chain before consumption that provides or contributes to an FSO or ALOP, as applicable.' FSOs and POs are general risk-based objectives for a food commodity. An FSO can for example stipulate that the probability of survival of *Clostridium botulinum* in sterilized foods at maximum is 1 spore in 10^{10} cans. Such an objective cannot be tested by any practical microbiological method.

Although FSOs and POs are expressed in quantitative terms, they are not microbiological criteria, which are defined as the acceptability of a product or a food lot, based on the absence/presence or number of microorganisms including parasites, and/or quantity of their toxins/metabolites, per unit(s) of mass, volume, area, or lot. A microbiological criterion is designed such that the underlying microbiological test can be used in practice to verify that a batch meets a predefined level of safety. There are many specific elements defined in a microbiological criterion other than a particular microbiological method.

The microbiological criterion includes for instance the specific parameters of the sampling plan (*n*, *m*, *c*, and *M*), and also the analytical methods to be used and any actions to be taken when the criterion is not met.

The *m* value of a microbiological criterion is also a microbiological limit, but this is the limit related to the results of one sample that is taken. So *m* is the limit in one sample, the MC is the criterion for a lot and the FSO for all batches of a certain commodity in a country or region.

As an example we could define an FSO/PO and a microbiological criterion for *Salmonella* in apple juice:

The general quality/safety level can be expressed in an FSO or PO, that is required, for example, absence of *Salmonella* in 99.99% of 100 mL packages of apple juice. So the FSO is a very generic global target for all food products in a specific category and related to an acceptable level of risk or a public health goal.

For a specific product lot the microbiological criterion can be for example from the European legislation, as described in Textbox 11.

The microbiological criterion is thus clearly related to one specific batch of apple juice, including the *m* value which is in this case the absence in 25 g. Depending on the management of the processing related to this criterion, resulting from both the rejection of positive lots (direct effect) and actions to prevent too many lots being positive (indirect effect), it can contribute to the FSO/PO as given above.

Both microbiological criteria, FSOs and POs need to state the microorganism(s) of concern and/or their toxins/metabolites and the reason for that concern; the food to which the criterion applies; and the specific point(s) in the food chain to which the objective/criterion applies. The microbiological criterion however is clearly related to a specific batch of food,

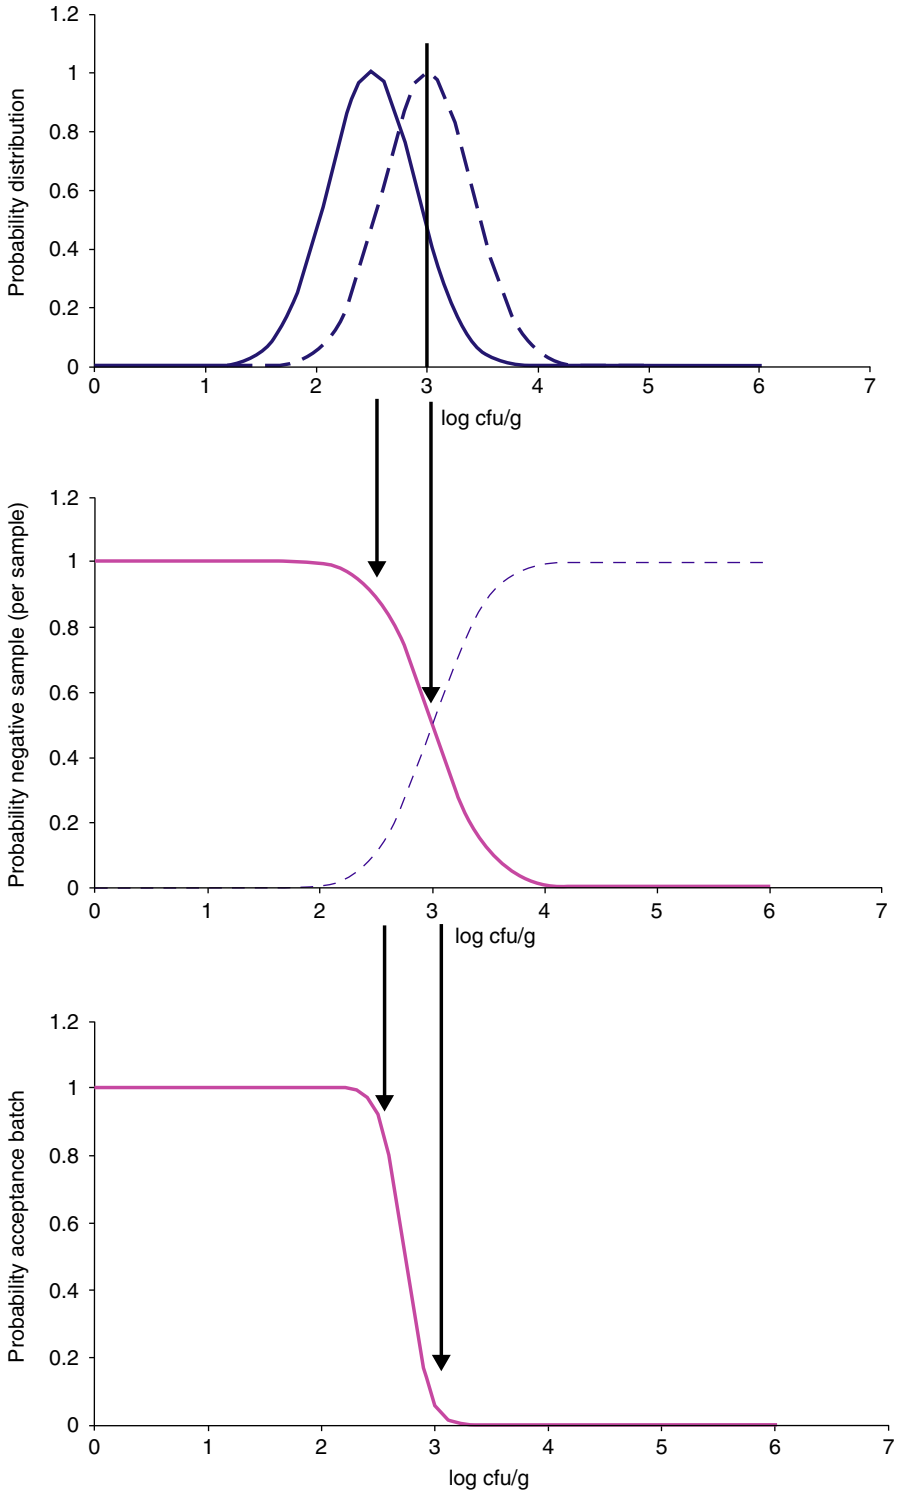

Figure 2 Two distributions describing the heterogeneity in a batch (with mean log$C$ 2.5 and 3 log cfu g^{-1} respectively and with a standard deviation of 0.4 log cfu g^{-1}), with below the probability when taking one sample from these distributions, to be either below (—) and above (—— equal to $P_{defective}$) an m value of 3 log cfu g^{-1}). With this $P_{defective}$ then in the bottom graph the probability to accept a batch giving a sampling plan with $n=10$ and $c=2$ is represented.

Textbox 11 Definition of an EU sampling plan for unpasteurized fruit and vegetable juices (ready-to-eat) for products placed on the market during their shelf life using as analytical method EN/ISO 6579

Microorganisms	*n*	*c*	*m*	*Class plan*
Salmonella	5	0	0/25 g	2

Where n = number of samples that must conform to the criteria: c = the maximum allowable number of defective sample units in a two class plan. m = a microbiological limit which, in a two class plan, separates good quality from defective quality.

whereas the FSO and the PO are general objectives for all batches of a commodity in a specific region or country.

Conclusions

Sampling plans are useful components within food safety management and quality control, however results should be interpreted with care, because results do not give an absolute indication of the quality of the batch under study. The cases as defined by the ICMSF give useful guidelines for selecting the characteristics of sampling plans, taking into account the degree of concern of the hazard and the conditions of storage and use of the product. By determining the performance of sampling plans or the OC-curves, a quantitative indication of the performance of sampling plans can be obtained.

FOOD SAFETY ASSURANCE SYSTEMS

Management of Allergens in Food Industry

RWR Crevel and SA Cochrane, Unilever, Bedford, UK

Glossary

Hazard A biological, chemical, or physical agent in, or condition of, food with the potential to cause an adverse health effect.

Hazard analysis critical control point (HACCP) A system which identifies, evaluates, and controls hazards which are significant for food safety.

Minimum eliciting dose (MED) The lowest dose of an allergenic food or protein demonstrated to cause a reaction in a food challenge (normally a double-blind, placebo-controlled food challenge)

Probabilistic (risk assessment) Risk assessment methods that produce quantitative risk estimates based on the distributions associated with the input variables (e.g., MEDs and food consumption) rather than point estimates such as the No Observed Adverse Effect Level or the mean consumption of a food.

Risk A function of the probability of an adverse health effect and the severity of that effect, consequential to a hazard(s) in food.

Risk assessment A scientifically based process consisting of the following steps: (1) hazard identification, (2) hazard characterization, (3) exposure assessment, and (4) risk characterization.

Introduction

The recognition of food allergy as a food safety issue by the food industry dates back to the 1990s, and its public health importance was affirmed in a Food and Agriculture Organization of the United Nations–World Health Organization (FAO–WHO) Consultation in 1995. The growing prevalence of allergies and the severity of reported reactions to foods combined to highlight its public health significance and spurred regulatory efforts to address it. Recent evidence indicates that the implications of food allergies to the affected individuals extend beyond the immediate potential health impacts to significant influence on quality of life.

For practical purposes, no cure exists for food allergy, and allergic consumers can therefore only manage their condition by avoiding foods, which contain the relevant allergenic ingredient(s). These may be present deliberately, as part of a product formulation. However, food production and manufacturing practices mean that allergenic constituents may also be present inadvertently, perhaps because they occur in the raw materials used or are carried over in small amounts from a previous product during manufacture. This inadvertent presence is not formally regulated under labeling legislation, but is arguably covered under more general food safety law, such as the EU's Regulation 178/2002 (EC).

A key issue has been how to assess the risk from this unintended presence of allergenic material and protect allergic consumers. Lack of data and knowledge, together with the potentially severe consequences, resulted in the widespread use of precautionary labeling (e.g., 'may contain peanuts'), a somewhat unique feature of allergen labeling and management. However, recent years have seen the generation of data and development of models that offer the possibility of quantitative risk assessment. Although this is a critical aspect of managing the risks from the unintended presence of allergenic residues, equally critical is knowing how allergenic residues may find themselves in products in the first place. An important insight was that effective allergen management needed to be integrated into overall food safety management not only so that allergens are taken into account at all points, but also so that the impact of allergen control measures on other food safety endpoints can be considered and, where necessary, mitigated.

Although allergens can provoke reactions rapidly and in small doses, a particular challenge for allergen management remains that, for practical purposes, allergenic constituents cannot be excluded from manufactured food products, and therefore most manufacturing sites, as many are important and valuable sources of nutrients.

Food Allergy

Food allergy describes a condition where an immune response to a food occurs in an individual and a subsequent encounter with the food provokes an adverse reaction. Foods can induce many different types of immune and allergic responses, but the current public health concern lies principally with those in which IgE antibodies are produced to proteins in the food. These antibodies are then implicated in immediate-type

 doi:10.1016/B978-0-12-378612-8.00364-4

reactions on subsequent exposure. Such reactions can vary from very slight to severe and occasionally fatal, depending on the dose, the individual, and other factors. Food allergy affects a higher proportion of children than adults, and reactivity to some allergenic foods, such as milk and egg, tends to be largely outgrown, whereas allergy to others such as peanuts generally persists. Little is known about why allergy to certain foods develops, although exposure and its pattern, the characteristics of the implicated proteins, and also the characteristics of the allergic individual, such as atopy, play a role. The minimum doses required to elicit an observable reaction range from microgram to gram amounts. Until recently, the distribution of sensitivity in the allergic population, as expressed by minimum eliciting doses (MEDs) remained uncharacterized, making risk assessments arduous and fraught with uncertainty. However, recent work analyzing results from double-blind placebo-controlled food challenges (DBPCFC) conducted under well-defined conditions demonstrates that sufficient data are available to characterize the response to many allergenic foods of public health importance, such as peanut.

Where prevalence has been estimated, data indicate that food allergy affects approximately 2–4% of the overall population, with a higher proportion among young children. Milk and egg are common allergenic foods among infants worldwide, but considerable diversity exists among older population groups, both with regard to the prevalence of allergy to different foods within populations and between populations. Management of the public health risk from allergenic foods also requires an understanding of which foods provoke allergies in particular regions or countries.

Avoidance of the offending food remains the only way of preventing reactions. Accurate labeling of food products, where the allergenic constituent is not obvious, is therefore critical to the safety of people with a food allergy. Legislation now recognizes this in countries covering over a third of the world population and mandates the labeling of allergens of public health importance among their populations. In contrast, the unintended presence of allergenic constituents is not specifically regulated, but instead relies on the voluntary use of precautionary labeling to warn allergic people to avoid the food. However, the absence of commonly agreed standards for its application and the uncertainty over the risk posed has led to its pervasive use. Evidence indicates that this extensive use impairs the quality of life of people with food allergies, particularly through severely limiting their food choices, and leads to risk taking. This situation feeds the fear of reaction, which is a documented feature of the environment of a proportion of food-allergic people.

Food Allergens as Contaminants

Unintended allergenic constituents in a food can unquestionably be considered as contaminants. However, they differ from the more usual chemical or microbiological contaminants. First, any one allergenic substance poses a risk to a comparatively small proportion of the population, the prevalence of allergy to any particular food rarely exceeding 2%. Second, and significantly, many allergenic substances constitute important sources of nutrients, which could not be readily replaced and are used in often large quantities in food manufacturing. They are therefore ubiquitous and often extremely difficult to remove completely while maintaining the economic viability and sustainability of the operation. Because allergens are natural components of foods, the term cross-contact is usually used to refer to unintended presence of allergens, particularly as a result of transfer during manufacturing processes. Most stakeholders now accept the impossibility of reducing risk to zero, particularly in view of risk-taking behaviors resulting from the widespread use of precautionary labeling. Furthermore, measures to reduce allergen contamination can also impact on other aspects of food safety (e.g., microbiological safety) as well as the environment and use of resources (e.g., water). Thus, risk minimization is probably a more appropriate objective of allergen management.

Food Safety Systems and Their Requirements and Limitations

Several international as well as national documents provide direction and guidance on the requirements for food safety systems, including the Global Food Safety Initiative (GFSI) Guidance document and ISO 22000:2005. Associated with those documents are prerequisite programs (PRPs), an example of which is the Publically Available Specification 220:2008, developed by the British Standards Institute in collaboration with the food industry. All these documents recognize that the effective management of allergens can only be achieved if it is integrated with food safety management systems to manage other food safety hazards. Integration not only ensures that food allergy is properly considered as a hazard, but also that measures taken to mitigate it do not aggravate other food safety hazards. Prerequisite programs defined in the context of good manufacturing practices also provide a sound basis for allergen management but are not sufficient on their own. The principles of hazard analysis critical control point (HACCP) analysis can be readily applied to allergens, even though the current lack of agreed management action levels remains a significant drawback. Examples of possible critical control points include sanitation and labeling verification.

Practical Application: What Needs to be Done?

Allergen management implies actively dealing with allergens when making food products so that allergic consumers can make safe choices. It requires knowing where and what allergens are present throughout the food manufacturing process, deliberately or, perhaps even more importantly, unintentionally. It is also about assessing the residual risk if an unintended allergen cannot be completely removed from a product and communicating it clearly and accurately to consumers. Allergen management thus concerns the whole supply chain from the farm to the final consumer and requires accurate and comprehensive information about allergens from all those stages. Assessment starts from an analysis of all the

stages leading from raw materials to finished products to identify the probability and extent to which this happens. It follows that a manufacturer must consider and understand the allergen status of all raw materials and processes involved in manufacturing the product in question. Implementation of allergen management demands significant resources and therefore requires engagement of senior management within companies, as recognized by the Food Safety Management Standard ISO 22000:2005.

Underlying allergen management, as well as food safety generally, are PRPs, which describe the basic conditions considered necessary to assure safe food production. These include considerations of premises design, hygiene, etc. and will not be described here as they are general food safety requirements.

Allergen management requires firstly identification of all sources of the allergen risks, then assessment of those risks and subsequently their management. This will be an iterative process, since, having identified a risk and determined that it is significant, the first step will be to look at ways of reducing it. Allergen risks can occur at all stages of the food manufacturing process, which can be summarized as design, sourcing, manufacture, and delivery.

At the design stage, key considerations include product composition and ingredient specification. An allergen's contribution to product functionality should be critically assessed and the feasibility of substitution or omission considered. Ingredient specifications are also critical, particularly in respect of unintentional presence of allergens. For instance, a 'gluten-free' claim would require assurance from suppliers of absence of gluten, supported by evidence that their ingredients meet appropriate specifications. The measures required to manufacture the product so that no additional allergen risks created need to be considered, particularly if a new allergen is introduced to a site.

At the sourcing stage, comprehensive, accurate, and reliable information about the ingredients is critical. Supplier questionnaires should provide information about their allergen management, such as their understanding and application of processes such as HACCP. Scrutiny of 'may contain' disclaimers and statements may be needed better to understand the resulting risk, whereas quantitative information may need to be sought to permit a quantitative risk assessment. Periodic audits, either by the company's own auditors or by auditors, accredited under the major standards (e.g., British Retail Consortium, International Featured Standards (IFS), GFSI) should support this process. Suppliers must also understand that they cannot change a formulation or specification without agreement. Making provision of appropriate (i.e., suitable for use in risk assessment) allergen information a contractual requirement is strongly recommended.

At the manufacturing stage, detailed knowledge of the design and operation of the plant are imperative to the successful management of allergens. Critical elements include identifying where the risk of allergen cross-contact arises and devising systems to minimize it. Parts of the manufacturing system through which the ingredients do not obviously flow can seriously challenge attempts to manage allergens as well as validation studies. The filters used to protect machinery in vacuum/pneumatic material transport systems are a good example. If they are not cleaned or replaced at appropriate intervals, product residues build up on them, which can be released at random intervals into product. As a result, the quantitative risk assessment based on validation studies can be totally negated. Measures to minimize cross-contact include allergen segregation in both space and time, including careful design of storage areas to minimize potential contamination in the event of spills, dedicated equipment, and, occasionally, whole lines or facilities, where feasible. Production scheduling effects separation in time and is a powerful measure in allergen management. However, the complexity involved should not be underestimated because allergens are not the only variables that need to be taken into account, with flavor and color among two other important considerations. Of course, each allergen needs to be considered individually too.

Cleaning also separates allergens from other components and each other, both in time and space. Protocols need to be validated to ensure they achieve their purpose and then need to be periodically verified. Indeed cleaning can also be considered as a critical control point in a HACCP plan. Validation, discussed in more detail later, usually involves analytical measurements, but a visually clean standard may be sufficient for accessible parts.

Finally, measures that can only be implemented as part of a longer term plan include equipment selection and factory design.

The delivery stage is the one at which the product is brought to the consumer. Failures at this point account for a significant proportion of allergen alerts (e.g., UK Food Standards Agency reports). Critical attention to artwork is needed to ensure that the correct packaging has been used and that all allergens are listed and clear to the consumer or purchaser. Controls include, for instance, ensuring that label rolls for previous products are removed from packing line after a product run. Use of bar code recognition systems can reduce the possibility of errors at this point. At this stage the packaging should be checked for incompatible elements, such as a 'dairy-free' logo but with milk in the ingredients. The packaging is also the vehicle for any precautionary labeling that a risk assessment has shown to be required for the product. This will include verifying whether suppliers' precautionary statements on ingredients and raw materials warrant carrying through to the final product. However, precautionary labeling can never be a substitute for good allergen management measures and does not, of itself, exonerate the manufacturer from any legal liability. If an allergen box is used, then this also needs to accord with the ingredients list: product recalls have occurred as a result of discrepancies in this area.

Allergen Management Plans

Allergen control (management) plans summarize all the necessary elements that must be checked in order to determine the allergen status of a specific facility and define the control measures that may be needed. It can thus be developed as part of the more general HACCP plan, considering the flow of materials through the factory. The Allergen Control Plan can therefore follow the schema outlined in Table 1.

Table 1 Components of an allergen management plan

Raw material sourcing
● Is the specification of raw materials and semifinished ingredients accurate and comprehensive with regard to allergens?
● Can the allergen risks be accurately assessed from the specification?
● Have all allergenic materials that are used at the facility been categorized?
Raw material receipt and storage
● Could cross-contact occur between raw materials during transport?
● Could raw materials be stored in the wrong location?
● Is segregation of allergens from other raw materials and each other ensured during storage, even in case of failure to contain them?
Manufacturing operations
● Are material flows comprehensively described and understood so that all possibilities for cross-contact have been identified?
● Have all operations where cross-contact can take place been identified?
● Have the opportunities for scheduling (e.g., nonallergen before allergen) been explored and implemented?
● Are formulations positively checked?
● Is work in progress properly labeled?
● Is rework of products containing allergens controlled?
● Do procedures exist to avoid mispackaging?
● Do protocols exist for all cleaning operations and have they been validated?
● Are cleaning operations verified and how?
● Has a study to validate allergen management at the facility been conducted and documented?
● Are there procedures to avoid inadvertent introduction of allergens into manufacturing areas (e.g., on clothing, tools, etc.)?
Personnel and training
● Have all personnel, including part-time and temporary staff, trained in allergen management to a level appropriate to their role?
● Is basic allergen training included in staff induction procedures?

Evaluating the Risk from Allergens

Thresholds and Hazard Characterization

Knowing what amount of an allergenic food can be tolerated by what proportion of the allergic population is a critical consideration for assessment and management of the resulting public health risk. For many years, this remained the most striking knowledge gap. Although regulatory authorities and others considered that thresholds below which reactions do not occur exist, they cannot be defined. Considerable data have now been acquired from studies using DBPCFC for many of the most important allergenic foods. Statistical modeling of dose distributions using data on MEDs from food challenges has proved very successful in filling this gap for several allergens while avoiding the difficulties of defining an absolute (population) threshold or no observed effect level experimentally and is now widely accepted. The principle of this approach consists of plotting the individual MEDs from controlled food challenges against the frequency of reaction to derive a cumulative population dose distribution, which can then be fitted to different statistical models. This approach helped to define eliciting doses corresponding to amounts of allergen predicted to cause reactions in small proportions of the allergic population (5% or less). These studies reveal that the range of reactivity spans amounts from micrograms to grams, but the proportion reacting to very low amounts is actually quite small. For peanut, the most extensively studied food, data on upward of 450 patients have now been identified and modeled (Figure 1). Indications are that 10% of peanut-allergic patients from clinics react to a dose of between 10 and 15 mg of whole peanut and 5% to a dose of approximately 5 mg.

Risk Assessment for Food Allergens

Risk assessment implies probability and, therefore, involves a number of factors in addition to dose distribution. At the population level, the probability of a reaction to an allergen depends on the prevalence of allergy to the food, the amount present, the likelihood that an allergic person will consume the product (in sufficient amount) and that person is sensitive enough to react to the amount of allergen consumed. Both the probability that an allergic person will consume the product and the amount present can be influenced by other factors. Ideally, a precautionary label would result in avoidance of the product by the relevant allergic individuals. In practice, observance of the warning can be quite low ($<50\%$). The reasons for this are complex, but they include lack of credibility as well as consumer confusion over the message, no doubt exacerbated by the large number of different precautionary statements. The statistical modeling approach can help to define quantitative action levels because information about the extent of consumer compliance with precautionary labeling as a function of its prevalence can be factored in as an additional quantitative factor (Figure 2). The distribution of unintended allergen in the product population is another variable, which can be included. The same estimate of cross-contact for products made according to different processes, using worst-case assumptions, may also mask completely different allergen distributions and consequently risk profiles. Probabilistic approaches open the possibility not only for more refined quantitative assessment of the global public health risk from a category of products, but they can also be applied to specific processes and actively help to improve management of allergens by enabling the investigation of particular scenarios to see which are most effective in minimizing risk.

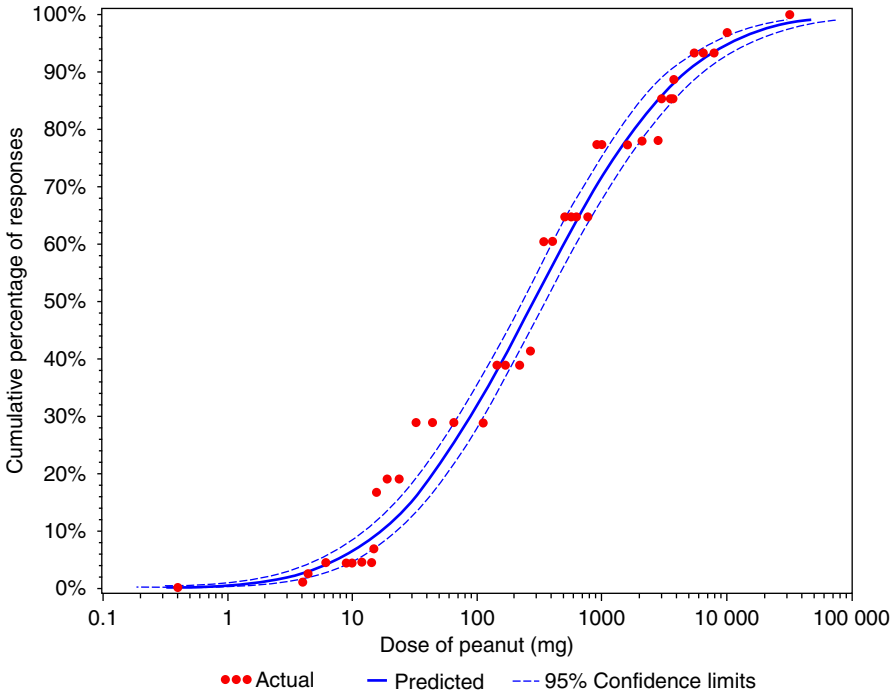

Figure 1 Dose distribution for peanut. Reproduced with permission from Taylor SL, Moneret-Vautrin DA, Crevel RW, *et al.* (2010) Threshold dose for peanut: Risk characterization based upon diagnostic oral challenge of a series of 286 peanut-allergic individuals. *Food and Chemical Toxicology* 48: 814–819.

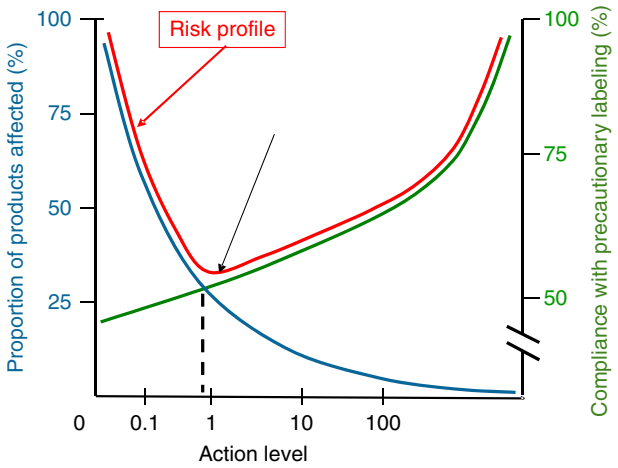

Figure 2 Postulated relationship between extent of use of precautionary labeling and observance.

Currently, there are neither generally agreed quantitative standards defining when unintended food allergens should be declared nor how validation results should be interpreted. However, there have been some attempts in different parts of world to provide labeling guidance. In Switzerland, an action limit for labeling of 1 g kg^{-1} (one part per thousand) was defined in 2001, and in Australia and New Zealand, the Allergen Bureau (an initiative of the Australian Food and Grocery Council) developed and recently revised the voluntary incidental trace allergen labeling (VITAL) system. The system includes a set of action levels that define when a precautionary label is deemed necessary to protect allergic consumers, based on clear levels of risk derived from available food challenge data.

Severity is also an important component of risk, but the relationship between dose and severity remains ill defined. In food allergy, consumption of the allergen may result in barely perceptible signs at one extreme and death at the other. For many years, not only was the proportion likely to react to a defined dose unknown, but also reactions to any particular dose were also thought to be unpredictable. Although a number of extrinsic factors (e.g., infection, stress, etc.) affect

the outcome of exposure to allergen, the dose itself is now recognized to be critical. Other recent studies provide information about the likely proportion of severe reactions in particular groups, which can form the basis of some reference points for setting limits in a public health context, such as the reference dose recently proposed as part of the Australia–New Zealand VITAL program. Once defined, the probability of a severe reaction could easily be incorporated into the probabilistic models described as an additional criterion.

Operational Aspects

Risk assessment as described above requires access to significant resource and expertise, which may not be readily available to smaller or even medium-sized food operators. The starting point in these cases will be identifying where allergen risks arise throughout the production process and managing them according to their likelihood and the consequences of possible failure to address them. These can be ranked on relatively simple qualitative scales, such as 'unlikely' to 'likely' and 'mild' to 'severe'. Likelihood that failure would be undetected can also be incorporated into this assessment. Taken overall, an assessment based on those elements will help the operator focus on managing those situations, which are most likely to result in harm to the allergic consumer. Table 1, summarizing the elements of an allergen management plan, provides an outline of relevant sources of allergen risks.

Allergen Cleaning Validation Studies

Validation and Verification

As described earlier, unintended allergenic constituents in a product can pose a risk to allergic individuals. Total avoidance of cross-contact and therefore absence of specific allergens from products where they are not part of the formulation is not always practicable. Therefore, an analysis of the risk arising from the residual allergen is required to ensure that precautionary ('may contain') labeling is only applied when absolutely necessary in order to maintain the value of such warnings.

Validation is the process of checking whether or not current allergen management procedures, particularly cleaning procedures, control allergen cross-contact to an acceptable level. Verification is checking and recording that validated procedures, which are being implemented.

Allergen Detection Methods

Allergen detection down to appropriately low concentrations is critical to effective validation and verification. A variety of methods are used for allergen cleaning validation studies, and the most common are listed in Table 2 along with their major advantages and drawbacks.

Enzyme-linked immunosorbent assays (ELISAs) are currently the most commonly used allergen detection tests, but although quick, sensitive, and relatively simple, they suffer from a number of disadvantages that require careful consideration.

- ELISAs rely on an antibody reaction with a protein(s). Proteins exist in different forms and relative abundances in different foodstuffs. Thus, antibodies in an ELISA may have been raised against a different mixture of proteins to those present in the potential contaminating material. Target protein(s) can also differ between ELISA kits that have the same purpose, for example, ELISAs for milk may detect beta-lactoglobulin or casein or a mixture of milk proteins. Therefore, knowledge of the protein composition of the allergen source is required in order to ensure the correct choice of kit and for the interpretation of the data.

Table 2 Common methods used in allergen cleaning validation studies

Method	*Target*	*Main advantages*	*Main disadvantages*
Non-specific methods ● Visual check ● Adenosine triphosphate (ATP) ● Total protein	N/A ATP Protein	Rapid and cheap	Only apply to accessible areas and equipment dependent Lack of specificity Possible false negative results Positive results difficult to interpret
DNA Detection methods ● Polymerase chain reaction (PCR)	Species-specific DNA sequences	DNA is relatively stable Usable when in absence of suitable ELISA Confirmatory technique alongside an ELISA	Indirect indication of potential allergen presence Negative result does not confirm lack of allergen Requires highly trained laboratory staff and equipment: expensive, and time consuming
Antibody-based detection methods/immunochemistry ● Enzyme-linked immunosorbent assay (ELISA) ● Lateral flow/dipstick devices	Allergenic/antigenic protein	Measures allergenic component, i.e., protein Sensitive (ppm) Relatively fast Quantitative Relatively cheap, rapid, and simple to use	Not available for all common allergens Different protein targets for the same allergen and different performance Extraction of target proteins from samples and/or ability to detect them variable Lateral flow devices qualitative (semiquantitative at best)

Positive control standards of similar composition to the contaminating material should be used to calibrate the assay.

- Food processing can alter proteins and their ability to be detected or extracted and therefore measured. ELISAs may thus produce a false negative result or quantify inaccurately for heated, fermented, and hydrolyzed products.
- ELISAs require the extraction of the protein into an aqueous environment before analysis. The efficiency of this extraction can vary considerably and should be checked using a 'spike and recovery test' where the allergen is mixed into and recovered from the matrix of interest, known to be free of the allergen. The food matrix can also affect ELISAs directly, for example, some ingredients could cross-react with the antibodies in the ELISA to give a false positive reading and others may produce color backgrounds that need to be controlled for.
- Both ELISA and PCR require a degree of technical expertise and comprehensive understanding of the materials and matrices involved. Thus, whether an in-house laboratory or an external one is used, it should be accredited with a recognized scheme and participate in proficiency testing.

Design of Validation Studies

Starting with a qualitative risk assessment and then moving onto a semiquantitative is recommended in order to determine whether or not an analytically based validation study is required or applicable. For example, it is sometimes possible to estimate levels of allergen carryover from one production run to another by 'worst-case scenario calculations,' i.e., measuring how much material is left behind in a process (e.g., based on film thickness on equipment or weighing brushed out residual), what the levels of such material would be after dilution with the next product (or in the next process step), and what amount of the material is allergen and therefore allergen levels in the final product that could be consumed.

If an analytically based study is required, accurate and robust analytical results are only useful if the samples analyzed have been taken as part of a correctly designed study. This will include the sampling locations and procedures and subsequent analyses.

For a food product, development of a scientifically sound sampling plan includes a statistical analysis of the probability that all allergens are detected and ensures that any allergens present are accurately measured. Important sampling questions that need to be considered include whether the allergen is likely to be evenly distributed within the batch; the number of samples per batch that should be tested; which batches should be tested; which portion of a run should be tested; and how to obtain a specific degree of confidence about allergen presence (e.g., the potential carryover from skimmed milk powder, a nonparticulate material can be assessed analytically, which would be inappropriate if the contamination were particulate (e.g., nut pieces). For the latter, a visual inspection should take place after cleaning to ensure that no particulates are left, supplemented by enumeration to determine probability of occurrence. The build-up of allergenic material on process line/equipment (e.g., heat exchange plate) also needs to be assessed, as it can be a source of random contamination).

Table 3 Considerations for an allergen validation study

1. Define and document procedure to be validated
2. Define and understand the potential 'contaminating' material
3. Define what and how to sample
   a. Surface sampling (swabbing)
   b. Rinse/push materials
   c. Final product
4. Include appropriate control samples
   a. Negative control – matrix free from the allergenic ingredient
   b. Control containing known amount of allergen (positive control)
   c. Standards of the same composition as contaminating material (in addition to kit standards)
5. Define in the study protocol how to take, label, and store samples
6. Define how results will be interpreted in terms of risk assessment

Table 3 summarizes the six main points to consider in the design of an analytical validation study to ensure that it is fit for purpose.

Verification

Cleaning processes should be periodically verified to confirm that they remain effective. If changes are made that might impact allergen management, for example, design alterations to a process line/equipment a revalidation should be performed.

Examples of Validation Studies

Example 1. A worst-case scenario calculation

Does soy lecithin carried over into non-soy-containing products made on a shared line, present a risk to consumers?

- Highest soy lecithin content in any recipe: 25 mg kg^{-1}
- Protein content of soy lecithin: 1000 mg kg^{-1}
- Worst case carryover: 3%
  - Maximum carryover: $25 \times 0.001 \times 0.03 = 0.00075$ mg kg^{-1} soy protein
  - Amount of soy protein in a 200 g serving of product: 0.000 15 mg
  - Soy reference dose based on VITAL 2.0: 1.0 mg
- Conclusion: negligible risk

Example 2. An analytically based cleaning validation study

Are the cleaning protocols adequate to control unintended milk presence in nonmilk products?

- HACCP assessment suggested a minimal extent of cross-contact
- Validation study discussed and designed with experienced accredited laboratory, who then conducted the analyses
- Rinse water sampled in all loops of cleaning-in-place (CIP) system, as well as final product
- Rinse water contained 2 mg kg^{-1} beta-lactoglobulin (equivalent to 3–4 mg kg^{-1} whey protein)
- Rinse water volume is 20% of batch size component of product and that constitutes 25% of final product.

- Concentration of whey protein in product: $3–4 \times 0.2 \times 0.25 = 0.15–0.2$ mg kg^{-1}
- Product serving size: approximately 20 g
- Whey protein per portion: 0.003–0.004 mg
- ED1 for milk (VITAL 2.0): 0.1 mg, i.e., approximately 0.02 mg whey protein
- Conclusion: risk negligible, no precautionary labeling required.

FOOD SAFETY ASSURANCE SYSTEMS

Management of Supplier and Raw Material

B Pourkomailian, McDonald's Europe, London, UK

Glossary

Culture Attributes exhibited by people through their behavior as a result of what was inherited, formally studied, and experienced.

Global Food Safety Initiative (GFSI) It was launched as a nonprofit making foundation in 2000, to achieve harmonization of food safety standards that would drive and reduce audit duplication throughout the supply chain.

Good hygienic practice (GHP) These are standard practices often used in order to achieve/maintain good hygiene.

Good manufacturing practice (GMP) These are standard practices often used in order to achieve/maintain good manufacturing.

Hazard analysis critical control point (HACCP) A food safety management tool focusing on the hazards and the steps in food manufacturing which are critical to food safety.

Supply chain The successive stages in food production, often beginning at the farm/field through to customer delivery.

Introduction

Every business establishment has a supplier and a customer; together they form the supply chain. Depending on the scope under discussion, the supply chain may have two or more components. A simplified generic linear supply chain may have six components consisting of the farm/field, raw material processor (e.g., miller), secondary processor (e.g., bakery), warehousing, retail, and consumer. This is presented graphically in Figure 1. In reality, this chain is not entirely linear, but cyclic, with waste material forming one of the foundational inputs of the growing step at farm/field. Also each component would often have more than one supplier and one customer. For simplicity and more focused approach to explore supplier management, reference would be made to one supplier providing raw material to one customer.

As each component of the supply chain has raw material supplier(s) upstream, and customer(s) downstream, it has to be able to manage its supplier(s) and the ingredient(s). Naturally, the selected component of the supply chain is itself a supplier of raw material to its customer downstream; as such similar expectation should be in place in its own facility as those it would impose on its supplier.

Several management system controls used by each supplier in the chain are similar, if not the same, with respect to food safety. The same would apply with regards to the tools used for management of food safety. Several studies have delved in and described these management tools in great detail, such as good practices and hazard analysis and critical control point (HACCP). These tools shall be addressed here, but not in great depth, because they will be covered in other articles of this encyclopedia.

Management of suppliers and ingredients are assisted by the tools described above (GMP, HACCP, etc.), and others such as ingredient and product specifications, regular reviews of performance and audits. But often, a major part of management requirement is overlooked, specifically the organization and the personnel within it and their expertise. In this article some of the requirements for supplier and raw material management for all three perspectives will be reviewed, i.e., organization, personnel, and supplier management tools used by the latter two entities.

The Organization

A manufacturer may be large, medium, or small in size, but their ethos toward management of their suppliers and raw

Figure 1 Supply chain example.

 doi:10.1016/B978-0-12-378612-8.00365-6

material could be similar. It is often this similarity that attracts them to each other. This is so because they all believe that 'rubbish in rubbish out' is not a cliché, but a fact that cannot be ignored if one is aiming for the provision of a good product. Therefore, to provide top quality product to the customer, one has no choice but to choose top quality raw ingredients provided by top quality suppliers.

However, identification of a quality supplier who can provide the desired ingredients is not an easy task. How would one identify a good supplier? What is it that one would look for in an organization? Would one recognize a top quality organization if one saw it? These are fundamental questions that need to be answered before the search can begin. The answers are often initially found when one begins to look inwards and identify its own standards. The application of 'lead by example' strategy is often a good start. This works because an organization, like people, would at first work with those of similar standing. In time, the organization will work with those who are better than itself, to initiate self-improvement. And when it has achieved a certain secure standing, it will begin to work with those with potential to rise to similar standards.

It is, therefore, the ability of an organization to be able to see itself for what it is and what it can achieve; that begins the process of setting standards for supplier and ingredient management, based on its own internal standards. All this begins with the company ethics that dictates their attitude toward their vendors and customers.

Naturally an organization is made up of people and it is the people who carry out the investigations necessary for identification, selection, approval, engagement, and management of the supplier and the ingredients.

The Personnel

One of the key components of a successful management system are the managers who are responsible for supplier and raw material management. Just as there are specific criteria associated with the managers of each department, the same applies for those assigned to food safety. As in any other profession, there are desirable attributes that are necessary to be able to manage food safety systems of a supplier and the raw material successfully. Listed below are some of the qualities that are sought when identifying a supplier and raw material manager with regards to food safety:

- Relevant education.
- Appropriate hands-on experience.
- Ability to translate science into layman's terminology.
- Resourcefulness.
- Reporting capabilities.
- Sense of responsibility.
- Sense of accountability.
- Honesty.
- Sharing similar ethics with that of the company.
- Cool headed.
- Respectful.

Some of the above-listed requirements appear as personality traits, which are arguably more important than formal education. It is these 'soft' competencies that are derived from a person's culture, and it is a person's culture that may be very influential when managing suppliers. The subject of culture is an important and intriguing one, which will be covered in other sections of this encyclopedia. With the necessary personnel selected and appropriately integrated into the company's culture, the manager can begin the process of supplier and raw material management.

The Supplier Management Tools

Managing suppliers and raw material within the supply chain is carried out by the organization's personnel under the 'personality' of the organization. These traits define the approach a manager takes, which are important in the overall management process. The tools and their use by the organization and its personnel form the practical application in management.

Supplier and raw material management has many facets and these can be divided and assessed separately. One of the directions that may be taken is defined below:

1. Supplier identification – The organizations identified for possible selection should be based on:
   a. Their ability to supply desired raw material(s).
   b. Their reputability.
2. Supplier selection – Of the identified suppliers, those who meet the necessary attributes listed below would be suited for selection:
   a. Share selecting organization's values.
   b. Assured supply.
   c. Assured quality (including food safety) of product.
   d. Appropriately qualified personnel.
   e. Works under a good quality (including food safety) management systems.

With the supplier being selected, engagement and working with the supplier begins. Approaching the supplier as a long-term partner in business is a winning approach. This is logical when one realizes that the success of one will naturally lead to the success of the other. Therefore, working together as partners would have a greater chance of success than working alone. Beginning the partnership requires building trust and it is at this point that verification of the food safety system is necessary to move the supplier into the approved phase.

3. Supplier approval – The supplier approval process is of vital importance for the vendor, as it provides information on the customer's expectations. By knowing the expectations the vendor can more effectively and efficiently meet the customer's needs. The requirements within the expectations will come in the form of internal process assessment through their quality (including food safety) management system. This system must have the criteria listed below:
   a. Prerequisite programme (PRP) – The PRPs needed depend on the segment of the food chain in which the organization operates and the type of organization. PRPs have historically been referred to as good practices and identified by the sector they apply to. Some examples of equivalent terms are good agricultural practice (GAP), good manufacturing practice (GMP), good hygienic practice (GHP) and good distribution

practice (GDP). PRPs consist of numerous requirements which are bundled together under one heading. Each requirement needs to be appropriately defined, developed and managed before establishing an HACCP system. PRPs for manufacturers may include topics such as, but not limited to:

i. Facilities and grounds.
   - Building exterior – The design, construction and maintenance must be in such a way as to protect the interior from contamination.
   - Building interior – The layout must be designed, constructed and maintained to facilitate GMP. Included in this area are walls, ceilings, air systems, processing area, lighting, and employee facilities.
   - Personnel and equipment movement – The movement patterns of materials, products and people shall be designed to protect against potential product contamination.
   - Waste handling – There must be systems to ensure that waste materials are identified, collected, removed and disposed in a manner that prevents contamination of products.

ii. Facility security – The facility must take appropriate security measures to prevent intentional harm to staff, product, processes, and building.

iii. Work environment – The working environment must be suitable to facilitate the production of safe and quality food. This would involve providing the appropriate layout, lighting, staff changing rooms and toilets, fit-for-purpose walls, ceilings, floors and drains.

iv. Equipment – All equipments used for the manufacturing of food must be of good hygienic design, calibrated, and well maintained.

v. Training – Appropriate training for new and existing employees.

vi. Material handling – Procedures must be in place to protect the food and food ingredients from contamination by all hazards. This involves storage, processing and transport.

vii. Pest management – An integrated program to prevent and eliminate pests.

viii. GHP – Personnel must abide by the set standards to prevent product contamination. The standards under GHP cover personnel cleanliness, hand hygiene, glove use, apparels, behavior, and health.

ix. Sanitation – A program must be in place to keep the facility, all food handling equipments and utensils under sanitary conditions appropriate to the processes undertaken.

x. Foreign material – All necessary steps must be taken to prohibit the contamination of product. This would require control of such items as glass, hard plastic, jewelry and loose items (production and personal).

xi. Chemicals – All necessary steps must be taken to prevent the contamination of product. This would include the control of cleaning and disinfecting chemicals.

xii. Good laboratory practices (GLP) – Accessing accredited laboratories that use standard analytical methods is recommended. The laboratory must have processes in place to ensure accurate and precise results.

xiii. Nonconforming products – Procedures must be established to prevent nonconforming products being shipped to customer.

xiv. Traceability – Systems must be in place to allow full traceability of the product and the ingredients forward and backward.

xv. Contractors – All such persons are to be given appropriate training to avoid increasing potential risk to product.

b. HACCP – This management tool would focus attention on the critical steps in food manufacturing and establish methods for their control. It would cover biological, chemical (including allergens), and physical hazards. In the initial stages of establishing an HACCP system, hazard analysis would be conducted to identify the potential hazard(s) associated with food production at all stages, from growth, processing, manufacture, and distribution, until the point of consumption. Also, an assessment of the likelihood of occurrence of the hazard(s) and identify the preventative measures for their control. At this stage some identified hazard will be deemed to be controlled through PRPs such as sanitation and segregation. Hazards not controlled through PRPs are managed through the establishment of CCPs which are the determined points/procedures/operational steps that can be controlled to eliminate the hazard(s) or minimize its likelihood of occurrence.

c. Full regulation adherence – All relevant applicable laws and regulation should be known and complied with.

d. Crisis management – An effective plan must be in place to manage contingency in light of a crisis. The plan should include such items as current contact details of customer and relevant employees and action plan protocol.

e. Internal and vendor verification – Similar processes that have been required from this organization should be transferred downstream.

f. Continuous improvement – The organization must establish processes to improve the effectiveness of its food safety (and quality) management system continually.

g. Management commitment and responsibility – The organization must have its management, at all levels, show commitment to the development and implementation of food safety (as well as quality) systems. This is demonstrated through appropriate policies, availability of resources, management reviews and timely and appropriate communication.

The provision for approval should be the successful verification of the above criteria. The verification is best performed by the appropriate customer personnel. It is important to note that for the approval of suppliers, it is best to verify the food safety management systems internally (by the customer) and not through a third party, where possible. The advantages are numerous, and to highlight but a few when approving the supplier with customer's staff, one would recognize clearly:

- Supplier attitude toward food safety.

- Does the supplier operate under the same culture as the customer?
- Do both parties share the same values?

On having approved the supplier, the next step would be to assess the quality of product, the customer's raw material that is being supplied. The authors will resume the discussion on raw material management later in this article.

Approved suppliers are often forgotten and not routinely inspected, especially to verify whether the materials they supply meet the requirements. It is of great importance to closely monitor the supplier standards and regularly verify, internally or externally, through audits and visits. It is always desirable to trust that the vendor shall provide material exactly to the specification. However, knowingly or unknowingly raw materials will at one time or other deviate from the set specification. It is therefore necessary to trust but verify.

One of the important measures in understanding supplier food safety management system is to take a video recording during the process verification activity. Subsequently, assessing the video would enable one to understand the strengths and weaknesses within the system. Also, identifying threats to the system and where opportunities for contentious improvement exist is important. In other words, conduct a strengths, weaknesses, opportunities, threats (SWOT) analysis. A good verifier would be able to conduct a SWOT analysis, naturally if permitted by the rules of the verification process. The competencies needed for such a person are defined in the Global Food Safety Initiative (GFSI) Guidance Document version 6.

Based on the findings of an audit, it will be possible to judge the frequency of future audits. The frequency can be based on qualitative or quantitative risk assessment, if needed. Auditing is by far not the only method of supplier adherence verification in supplier management. Maintaining and improving supplier relation can be managed through other means such as:

- Formal meetings:
  - reviewing and updating goals and objectives;
  - updating each other on the progress within each company;
  - exploring new projects;
  - reviewing audit results; and
  - reviewing customer complaints.
- Informal visits:
  - building relationships for more open interaction;
  - updating on the process and sharing best practices; and
  - improving communication process.

With good results from materials supplied and audits, the supplier can be retained on the approved list. Staying on the approved list would inevitably create opportunities for developing the partnership. Apart from the named process above in building on the existing relationship, further strength may be achieved through sharing values and aligning goals and objectives and even adopting each others' cultures.

On the contrary, if supplier performance deteriorates, steps must be taken to disapprove them. A judgment call must be made based on the risk the supplier and the raw material pose to the customer's business. The criteria for this action must be clearly defined at the supplier approval stage and agreed to. Listed below is a nonexhaustive list of criteria that may lead to supplier being delisted from a food safety perspective:

- Failing a food safety audit and failing again on the re-audit.
- Providing materials that do not meet the agreed specification.
- Deliberate provision of false information.
- Holding vital information that may lead to food safety concerns.
- Lack of commitment to food safety.
- Disalignment of cultures.

It should be possible to bring a delisted supplier to an approved list. The criteria for the same must also be clearly defined and agreed to during the initial approval stage. These may include:

- Correction of all nonconformities.
- Replacement of staff responsible for creating the issue leading to delisting.
- Improved commitment and its demonstration.

With the criteria for reapproval met, the customer may wish to keep the supplier on a temporary approval to rebuild trust. As such, more frequent visits and verifications would be necessary to regain trust in the supplier and the raw material is reinstated. Following this, the procedures for the supplier maintenance management would be in place as described earlier.

The Raw Material Management Tools

Suppliers receive raw material which they process into a product which in turn becomes the raw material of the customer for their product. The food safety management of the supplier's product, here referred to as the raw material, has to be reviewed and verified by the customer. After all the quality of the raw material defines the process needed to establish the necessary food safety standard of the final product for the customer.

To establish a baseline of the customer's requirement with respect to the raw material, a product specification has to be designed, shared, agreed and signed by both parties. This will be a legally binding document which will ensure what the customer wants and hence expects from the vendor. The specification must clearly define the product attributes. Listed below is a nonexhaustive list of the contents of the raw material specification:

- Name.
- Appearance.
  - Color.
  - Shape.
  - Dimensions.
- Weight.
- Packaging.
- Ingredients.
  - Allergens.
  - Preservatives.
- Chemical profile.

  - pH.
  - Water activity.
- Microbiological criteria.
  - Targets and limits.
- Sensory attributes.
  - Taste.
  - Mouth feel.
  - Odor.
- Transport and storage.
- Shelf life.
- Further processing (if applicable).

The product (raw material) specification is the agreement between the two parties, agreeing on one hand, what will be delivered and on the other, what is needed to be delivered. Therefore, it is important that both parties regularly analyze the raw material to verify that it meets the specification. With internal verification the frequency and sample size would vary depending on the material and batch size. With respect to external verification the frequency and sample numbers vary depending on the trust placed on the vendor. The level of trust comes with time and track record of meeting the specification. It is must be noted that pathogen testing by customer is rare. This is owing to the difficulties that the customer faces in taking correct and meaningful action when faced with a positive result for pathogens. In such circumstances, the customer and supplier must rapidly recall the product and address the issue with those who have already consumed the product. It is for such reasons that where pathogen testing is required, positive release procedures would need to be established at the supplier.

Depending on the criteria being assessed, appropriate laboratories need to be selected. Both the supplier and customer need to use a laboratory that is accredited against all relevant standards, where possible, and of reputable status.

The supplier should keep records of the laboratory tests conducted on the raw material and where necessary the corrective actions taken.

The customer should also maintain records of the laboratory tests conducted on the raw material on receipt of the material. If there are discrepancies, the supplier should be informed, so that they may implement corrective actions. This database would be defined as part of the customer complaint file and can be used to further develop the supplier approval status described earlier.

Conclusion

Managing suppliers and raw materials with respect to food safety and quality is a logical and common sense process. It consists of verifying adherence to standards such as GP, HACCP, and crisis management. These standards are common to all components of the supply chain with slight variation in focus depending on its position in the supply chain. Because of this commonality, it is always useful to select a supplier who has similar level of adherence to the standards as oneself. Although the food safety and quality management tools described is useful and necessary, there are two other factors in management that are also of great importance. The quality of the managers as well as the ethos of the organization is of key importance. It is this manager who has to define, review, and verify such systems.

The managerial attributes which would allow them to successfully manage the supplier and raw material, comes from their culture, education, and experience. Establishing the correct criteria for supplier and raw material approval, maintenance, and removal is fully based on the skills of the food safety manager.

The organizational culture plays a very important role on how the personnel behave and grow. The systems within are the defining criteria for employees to carry out the tasks for supplier selection.

Specifically defined and agreed to standards and measurements have to be verified regularly to ensure that the supplier is providing safe raw material. Based on internal and external verification of the supplier food safety and quality management system as well as raw material safety, the customer could establish the risk the supplier and the raw material pose. This risk is then managed through regular visits and verification processes.

In conclusion, an organization's ethics, selection of the appropriate food safety personnel, and providing them with the necessary tools are key factors in achieving successful supplier and raw material management. Having established this, the rest is relatively simple!

FOOD SAFETY ASSURANCE SYSTEMS

Documentation and Record Keeping

RF Stier, Consulting Food Scientist, Sonoma, CA, USA

Glossary

Critical Control Point A step at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Document Any written procedure or protocol that describes how something is done, demonstrates that a measurement or observation was made or supports a program.

HACCP plan A document prepared in accordance with the principles of hazard analysis critical control points (HACCPs) to ensure control of hazards that are significant for food safety in the segment of the food chain under consideration.

Hazard analysis The process of collecting and evaluating information on hazards and conditions leading to their presence to decide which are significant for food safety and therefore should be addressed in the HACCP plan.

Monitoring The act of conducting a planned sequence of observations or measurements of control parameters to assess whether a critical control point (CCP) is under control.

Record Written or electronic information that provides documentation that status on a procedure, whether an action has been conducted properly or has been completed or supports a program. Most records are maintained on forms designed for that purpose.

Step A point, procedure, operation, or stage in the food chain including raw materials, from primary production to final consumption.

Validation Obtaining evidence that the elements of the HACCP plan are effective.

Verification The application of methods, procedures, tests and other evaluations, in addition to monitoring to determine compliance with the HACCP plan.

Introduction

It is a law the world over that food, ingredient, and beverage processors must produce safe foods. Processors develop, document, implement, and maintain a wide range of programs to ensure that the foods they manufacture are safe and wholesome. These programs include prerequisite programs, such as cleaning and sanitation and pest management, a food safety management system (hazard analysis critical control point (HACCP)), quality management, production control, and food defense programs. The latter are aimed at minimizing the potential of an act of bioterrorism. Monitoring and the records that are the end result of the monitoring program demonstrate how effective the system truly is. Government officials and others have said:

> If it is not written down, it never happened.

This directly applies to records, but a proper documentation system is essential for all phases of a food processing operation. Procedures describe how programs are to be established or managed; work instructions provide line workers, the sanitation crew and others with detailed instructions as to how a task should be conducted, what records to keep, and what to do in the event if there is a problem. Forms, both hard copy and electronic, provide a means to monitor and record the activities related to quality, safety, and sanitation. These forms are filed as records, which provide a history that allows the processor, third-party auditors, customers and potential customers, and regulators to verify that the system is working as designed. Of course, these same records may also demonstrate lack of compliance and provide evidence as to why problems, such as foodborne illness, occurred.

Food processors are expected to develop many different programs. Table 1 shows a list of the kind of programs a processor should have. This is based on what must be done to ensure quality and safety, and meet the expectations of most of the third-party audit schemes. Procedures and work instructions, if needed, must be developed in each of these areas. The area, such as cleaning and sanitation, might have a general requirement for managing the program, plus a long list of specific work instructions as to how each piece of equipment can be kept properly cleaned along with floors, walls, drains, overheads, utensils, and whatever else needs cleaning. All procedures and work instructions must include the means of evaluating the activity to ensure that it is done properly and a form or some other means of recording that the work was done. The processor must also commit to training the work force on each procedure, which must be recorded. Training not only ensures that the worker understands how to do his or

her task safely and effectively, but it also protects the company and the worker. In an increasingly litigious world, failure to properly train workers could be deemed negligence if there is an injury or foodborne illness.

So, a well-managed document program will provide a large number of benefits to the company.

1. It describes how work should be done.
2. It provides a record that the work was done.
3. It provides materials to verify that the system is working.
4. It provides evidence when the system is not working.
5. It provides evidence that corrective actions were taken.
6. It provides support that the programs are properly designed (validation).
7. It provides evidence that workers are trained and competent.
8. It protects the business, employees, and customers.

Developing a Document-Control Program

Each and every processor should make a commitment to developing a document-control program. This program will help ensure the following.

1. Procedures and work instructions are developed using a standard format.
2. All documents and forms are subject to a review process before being put into use in the facility.
3. Only current protocols and forms are used.
4. Old or outdated documents are removed from circulation.
5. A record of how protocols have evolved is maintained.
6. There is an updated master list of all procedures, work instructions, and forms used in the facility.
7. Documents and records are protected from damage and are secure.

The processor should also appoint someone to manage the document-control program. This could be someone from the quality group or it could be someone whose title is simply Document Control Manager. This person's job is to manage the program. He or she need not be a technical person, unless part of their job description will be to review procedures, work instructions, and forms for content. If this is the case, someone with a technical background should be assigned to manage the program. If a company does not have a document-control program, the Document Control Manager will be responsible for developing the program incorporating the elements noted earlier. If the program is already established, their task will be to manage the program. He or she will also be responsible for developing a team to review and approve documents. Some companies assign responsibility for creating documents to specific persons in each operating group, whereas others allow anyone to do so provided they follow the procedures that have been established.

Each company has their own format for creating documents. There are, however, elements that are common to most. These include

1. Title – What is the name of the procedure, work instruction, or form?
2. Objective – What is the program supposed to do and why?
3. Procedure – How is the protocol to be done? This step provides the details and establishes expectations. It would also include information such as tools required, personal protective equipment (PPE) required, safety issues and required records, and how they should be monitored. If a specific form is required, that form should be referenced and even attached to the procedure itself.
4. Responsibility – Who is responsible for managing this area or doing the work described in the protocol.
5. Corrective actions – What should be done in the event that there is a problem, a critical factor is not achieved or the evaluation is unsatisfactory.
6. Footers – Many forms will also include information such as the date when the form was generated, a tracking number, revision number, who created the document, and who signed off on it.

Other sections that may be included are a scope, key words, and references. Some companies like to refere other procedures, supporting documents, or regulations in their procedures. The format is really up to each individual operation.

All of the procedures, work instructions, and forms should be entered into a Master List, which is updated as required. Headers in the Master List might include the document title, the number, creation date, last revision date, document number, department, and who created the document. All materials can be kept in one Master List, but for many companies, it is often easier to maintain separate lists for each department.

Another element that needs to be established is how to ensure security if the procedures and forms are maintained in electronic files. The Document Control Officer will need to work with the computer group to establish passwords, establish levels of access, and ensure that the system is backed up and protected.

Procedures and Work Instructions

Procedures and work instructions provide the road map for plant operations. They should be written so they clearly inform management and staff how things should be done, when things should be done, and how to document the work. These documents also form the basic for training and for internal audits. Auditors, both internal and external, must watch different operations to determine whether procedures are being followed as written. When an external auditor sees that one procedure is not being followed, he or she will often dig much deeper. They will assume that there are others that are in doubt.

As noted earlier, procedures often describe the expectations of a program, whereas the work instructions define how the tasks within the program shall be performed.

Table 2 shows a procedure for a glass and brittle plastic program. This procedure includes all the elements expected

Table 2 Sample format for procedures

Subject: Glass and brittle plastic program

Objective: Minimize the potential for crosscontamination of foods and ingredients with glass or brittle plastic to ensure that foods and ingredients are safe and will not result in injury to end users.

Procedure:

1. It is a company policy that there shall be no glass or ceramics carried into or used in the food processing area or warehouse at any time. Glass and ceramic shall be confined to the offices and break area. Watches must be removed before entering the plant. Eye glass lenses shall be manufactured from shatterproof materials.
2. Windows in production or warehouse areas must be shatterproof or coated/covered with plastic to contain breakage.
3. Inventory all glass and brittle plastics in areas where foods and ingredients are stored or handled. This includes the warehouse, production, and packaging areas. When conducting the inventory, note location of glass or plastic, the type of glass or plastic (if possible) and whether it is shielded or strengthened in any way. This inventory must also include the area or areas where glass is stored.
4. Transfer all information gathered in step #1 into a Master List.
5. Plant Management shall then examine the Master List for glass and brittle plastic and determine whether any of the situations existing within the plant pose a realistic threat of contamination and potential injury.
6. The potential risk (high, medium, low) shall be noted in the Master List with the date(s) of review.
7. Situations that pose a realistic threat (high) shall be addressed as soon as possible and corrective actions noted in the Master List. Corrective actions may include but need not be limited to the use of shields of covers, replacement with stronger or shatterproof plastics, or removal of the situation from the production or holding area.
8. The company shall establish a regular audit program to examine all glass and brittle plastic noted on the Master List to determine its condition. If any breakage is noted, it shall be noted on the Master List and repairs made immediately.
9. Employees shall be trained to report any broken glass or brittle plastic such as cracked gage covers or windows.
10. Whenever glass must be transported through the plant, it must be protected and contained in some way. For example, lights must be carried in their original box when being moved for replacement.

Responsibility: Production supervisor
Corrective actions:

a. Glass and brittle plastic breakage and cleanup
   If glass or brittle plastic breaks in the production area or warehouse, operations shall cease immediately.
   b. All exposed product shall be segregated and placed on hold.
   c. Workers in the area of the breakage shall not move throughout the plant so as not to spread the glass and brittle plastic through the plant. Shoes shall be inspected before leaving the area and cleaned if needed.
   d. Broken glass and brittle plastic shall be cleaned using designated tools and disposed of into designated containers.
   e. Glass and plastic breakage shall be recorded in a Glass and Brittle Plastic Breakage Log. This shall note the type of breakage, the location, whether any product was affected and the disposition of said product.
   f. Plant Management shall meet to discuss all incidents, determine the cause and implement a corrective/preventive action plan to minimize the potential for future incidents.
g. Discovery of damaged or broken glass or brittle plastic
   If cracked, damaged, or broken glass or brittle plastic is observed during audits, internal inspections or routine examinations of operations, it must be noted and evaluated immediately. Repairs shall be prioritized based on potential risk to the business.
   h. These incidents shall be recorded in the Glass Breakage Log.

from a glass and brittle plastic program. There are elements in this procedure that would require additional information. Work instructions for how to develop the glass and brittle plastic register, how to establish the degree of risk for each item on the register, and how often internal inspections should be done are not defined. These points need to be established and documented in a separate work instruction. There should also be procedures detailing how the glass breakage log should be establish and utilized.

From a food safety perspective, it is especially important that the work instructions that are developed for monitoring critical control points (CCPs) are clearly written and that they reference the record-keeping forms. Those responsible for monitoring should:

- be trained in CCP monitoring techniques, (company must document training and competence),
- fully understand the importance of CCP monitoring,
- have ready access to the monitoring activity,
- accurately report each monitoring activity,
- immediately report critical limit infractions so that immediate corrective actions can be taken, and
- understand the corrective and/or preventive actions that must be taken.

The procedures for doing the work need to be clearly written. Forms for monitoring should be simple to use, provide a space for entering the information being monitored, and an area where the operator can sign the form. It is a good idea to include the critical limits on the monitoring form so that information is easily accessible.

Not all records are done manually. Even if the records are continuously recorded on a chart or data are entered into an electronic system, there must be procedures for how the work is to be done.

One of the best tools that food processors can use when developing good, easy to use procedures is the digital camera. Incorporating pictures of instruments, equipment, or gages can help clarify procedures and minimize the potential for them being misunderstood. Pictures can also be used to emphasize what are good practices and what is unacceptable. As an example, most food processors have basic requirements for hair restraints, garments, eye protection, ear plugs, and other gear. Many facilities are seen that post pictures in their locker rooms or at the entrance to the plant to show workers what is and what is not acceptable. But the best use of photographs is with equipment operation. Many operations utilize startup checklists that provide the operators with step-by-step actions to follow and information that must be recorded. Using photographs reinforces the protocol and is an invaluable tool when it comes to training new operators.

As noted, forms should be considered controlled documents and should be included in the document-control program. There are a wide variety of forms that are used throughout the industry. There are several elements that should be part of each. These are

- form title,
- firm name and location,
- area to enter the time and date,
- product information (including product type, package size, processing line, and product code where applicable),
- area for actual observations or measurement,
- critical limits,
- area for operator's signature or initials, and
- space for reviewer's signature or initials, and date of review.

If a company has forms that they are using do not have a space for reviewer's signature and date, a stamp may be used with spaces for the entries.

One thing that should never be done is to print forms with preprinted information, such as time. The operator must enter the time, and when the measurement, or reading was made. It should not be on the form. In the reality of the production environment, record keeping is not done every hour on hour.

Monitoring and Record Keeping

Monitoring records are the heart of the HACCP program. Monitoring records show the following:

1. that the system is in control,
2. that the system may be going out of control, and
3. that the system has lost control.

As noted earlier, persons monitoring CCPs must be trained on the procedures and fully understand the importance of monitoring. This applies not only to persons doing monitoring CCPs, but also to all responsible for monitoring prerequisite programs, production operations, and any other element of the quality, safety, and sanitation program. They are all part of the food safety management system (FSMS).

One set of documents that each processor must maintain are calibration records for all instruments or equipment used to monitor CCPs, plus protocols for how these instruments or pieces of equipment are to be calibrated. The procedures for calibration must include how to do the work, who is responsible for doing the work, the acceptable tolerances and corrective actions to be taken in the event if an instrument or equipment is found to be out of calibration. The corrective actions must examine whether any food has been affected by an instrument that is out-of-calibration and describe what should be done with any affected foods.

There are basic requirements for how records should be kept. Many companies mandate that monitors use only blue or black pens to record information and go so far as to define what kind of pen is safe to use in the processing area. They will also define how corrections should be made.

"If operators make an error on a form, the error shall be noted by lining out the incorrect entry, inserting the proper result and initialing and dating the change" (Figure 1).

The procedures should state that corrections cannot be made by erasing an entry, the use of liquid paper, or tape. In the eyes of the regulators, these would be falsified records (Figures 2 and 3).

Monitors must also be taught that there are some things that they should never do. Many persons charged with monitoring will use entries such as ditto marks or lines to

indicate that the numbers are the same (Figures 4 and 5). This is unacceptable. Records have to be recorded at the time they were measured or observed. Ditto marks or lines drawn down the page do not provide that information. This is why forms with preprinted data are unacceptable.

Corrective Action Records

If monitoring shows a deviation at a CCP, the product in question is deemed to be unsafe or potentially hazardous. The processor must now take corrective actions to bring the system back into control and make a disposition of the product that was affected. Records of all actions to evaluate the deviation and dispose of the product must be maintained.

Corrective actions records must be maintained for all quality and prerequisite monitoring activities. In many cases, a corrective action may be noted on the record-keeping form. As an example, if a processor was using adenosine triphosphate (ATP) swabs to verify the efficacy of cleaning and a swab indicated that an area was not clean, the sanitation supervisor could record the swab results and the results from retesting after the suspect area was recleaned. In this case, the corrective action would be captured on the original monitoring form.

Corrective actions and records of these actions are one of the most common failings in food processing plants. All too often, the processor makes a correction but fails to document that it was done. They fail to close the loop. Failures to conduct corrective actions are very common when evaluating records of prerequisite programs. As an example, the pest control operator observes that a door is broken and does not fit tightly. He notes it on his report and the plant fixes it, but the plant fails to record that this issue was closed on the report or elsewhere.

It is expected that all deficiencies on internal audits, routine audits, and third-party audits will be addressed and there will be corrective action records of all actions taken to fix the problem. The quality group should verify that the work was completed properly by signing off on the corrective action report or in the corrective and preventive action (CAPA) logbook.

For routine corrective action issues, such as properly cleaning a piece of equipment or making a repair, how these issues are addressed is quite simple. They are simply cleaned or fixed. However, if there is a significant problem, such as a

Figure 5 A sample of improper records.

major deviation at CCP or a serious quality issue, the corrective action program and how it is documented becomes more complex. Again, how these issues are addressed must be defined in the procedures. With complex issues, the processor should define the problem, develop a written corrective action plan, create a time line, and move forward on the activity. When the work is done, they will notify the quality team who will then review the records and the results and approve or disapprove the work. Depending on the type of problem, they may recheck the issue at a later date to verify the actions were successful. Again, this must all be documented.

One tool used by many processors is a CAPA logbook. This may be retained as a hard copy or electronically. This log serves as a reservoir for all issues that required corrective actions and is used to track progress. Electronic logs seem to be more popular as they allow the quality group to easily track the status of corrective action activities. They can see what has been done and what is still pending. In addition, a well-designed electronic log allows problems to be sorted and high priority or regularly occurring issues can be addressed at greater length. The CAPA log is something that the HACCP team should review each time they meet.

Record Review

One of the seven HACCP principles is verification and part of verification is ensuring that all CCPS have been properly monitored. Food processors must be sure that a member of the management team has been trained to review all records of CCP monitoring. Ideally, this review should take place before the product is shipped. The reviewer must examine the monitoring records, be sure that the values are correct, and that they have not only been filled out properly, but were also signed by the monitor.

All calibration records, especially those done on instruments used to monitor CCPs, should also be reviewed on a regular schedule. Most companies will conduct such a review at intervals ranging form a week to a month.

The reviewer must sign and date the records following his/her review. If a space has not been provided for a signature and date, the stamp mentioned earlier may be used. It is also acceptable simply to sign and date the records.

Procedures should be drafted that describe how records should be reviewed and what should be done if deviations are observed. This is especially important when reviewing more complicated records such as those required for the production of low-acid foods. There may be many CCPs for such records. In addition, there may also be several different pieces that will require review. As an example, there may be the operator retort record, the recorder chart printout, and seam integrity records. All need to be carefully examined and issues highlighted.

Many companies bundle their daily production records and require that their quality personnel review all the records in the bundle, that is, food safety, quality records, and sanitation records. Processors who utilize this kind of procedure usually attach a cover sheet to the bundle listing all the required records that must be in the packet and are subject to review. The absence of a record would then be considered a deviation. The completed packet should include evidence that each record in the packet was not only present, but was also reviewed.

There are other situations where documents and records are subject to review: third-party audits and regulatory inspections. Each and every third-party audit, whether it is a company-owned system or one of the six schemes approved by the Global Food Safety Initiative (GFSI), entail review of procedures and records, plus evaluation of how the protocols are actually implemented. With these audits, all procedures, work instructions, and all kinds of records are subject to examination. The six schemes currently approved by are the British Retail Consortium (BRC), International Food Standard (IFS), Dutch HACCP, Safe Quality Foods (SQF), FSSC 22000, and Synergy 22000. The most stringent of all the food safety audits is that for International Organization for Standardization (ISO) 22000. Companies who make the commitment to meet the ISO 22000, FSMS are usually looking at 12–18 months preparation at a minimum, plus an intensive audit by the certifying body of up to 5 days.

Regulatory investigations also include review of records. The records that are available for review depend on the type of investigation and what the company is manufacturing. For example, in the US, there will be many more records available for review for a processor of low-acid foods than there would be for a manufacturer of soft drinks. Food processors need to understand which records the regulators are allowed to access and which are not. With the passage of the Food Safety Modernization Act of 2010, HACCP will become mandatory for food processors in the US. These records and others will, therefore, be accessible to regulators.

Therefore, since documents and records are an integral part of both third-party audits and regulatory investigations, it behooves a processor to properly develop, implement, and maintain these materials.

Record Storage and Retention

An integral part of the document-control and record-keeping program is storage and record retention. All records must be stored in a secure (locked) area where they are protected from water damage, fire, pests, and theft. Some companies have actually constructed what amounts to block houses for record storage. These facilities are built in a warehouse of cinder blocks and brick with a sturdy roof. They are air conditioned and have fire abatement systems; systems that rely on chemicals not water. The records themselves are filed in locked cabinets in the area and the companies adopt checkout systems if anything is taken out of the area. The document-storage areas are usually built with a reading room, so records can be viewed within the secure area. The storage facilities at most plants are nowhere near this elaborate.

There are also many companies that are turning to firms that will store documents for them off site. There are, however, regulations that mandate how long certain regulated products must retain records on site. These operations have all the features noted earlier. They also manage their files so that they can access things quickly and easily. If the processor contacts them and asks for specific records, they can usually be located and delivered within 2 h. The record storage companies will also notify the

processor when the records are scheduled for destruction. When they get approval to move forward, they will destroy those records scheduled for destruction and provide the processor with documentation that verifies which records were destroyed.

This leads to another requirement for records. How long should they be kept? The juice HACCP regulation in 21 CFR Part 120. 12 (d) states the following:

> (d) Record retention. (1) All records required by this part shall be retained at the processing facility or at the importer's place of business in the United States for, in the case of perishable or refrigerated juices, at least 1 year after the date that such products were prepared, and for, in the case of frozen, preserved, or shelf stable products, 2 years or the shelf life of the product, whichever is greater, after the date that the products were prepared.

Records for low-acid canned foods must be retained for 3 years; one of which must be on-site.

For products that are not regulated, one rule of thumb is that records should be maintained for the shelf-life of the product, plus 1 year. When determining how long to keep records, companies need to talk to their clients and the legal department. Processors who do contract packing are often required by contract to keep process records for longer periods of time.

Electronic records must also be protected and should be subject to the same storage requirements as hard copies.

All these protocols that describe how records are stored must be documented in a procedure. The basic procedure must describe storage requirements, retention times, and mandate that the records be destroyed at the end of the retention time, and that records be maintained of this action. In addition, if a company elects to store records off-site, there should be a procedure that describes the basic requirements for an outside storage facility, how the storage firm is selected, and what is done to monitor their performance.

What is Required for Food Safety

As this article has shown, there are many different records that make up the food safety management system. These include:

- HACCP plan and support documentation used in developing the plan,
  - Meeting minutes,
  - Technical references,
- Records of CCP monitoring,
- Records of corrective actions,
- Records of verification activities,
  - Including validation data and internal audits,
- Calibration records,
- Prerequisite programs,
  - Cleaning and sanitizing,
  - Hand sanitizers,
  - Any that have been determined to affect product safety in the company's hazard analysis, and
- Training.

There must also be procedures or work instructions that describe how each and every one of these tasks must be done. Without road maps provided in these protocols, it is simply not possible to ensure that the work is done properly nor is it possible to properly train new employees.

Is this a great deal of work? Of course it is, but consider the alternative: food, ingredient, or beverage that makes someone sick or causes an injury. One such incident will cost more in terms of money, headaches, and loss of face than what went into developing, implementing, and maintaining the program.

FOOD SAFETY ASSURANCE SYSTEMS

Labeling and Information for Consumers

D McCrea, Cardiff, UK

Glossary

Codex Alimentarius A collection of internationally recognized standards, codes of practice, guidelines and other recommendations relating to foods, food production and food safety adopted by the Codex Alimentarius Commission.

Control measure Any action and activity that can be used to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Food hygiene Comprises conditions and measures necessary for the production, processing, storage, and distribution of food designed to ensure a safe, sound, and wholesome product fit for human consumption.

Food safety control system The combination of control measures that, when taken as a whole, ensures food is safe for its intended use.

Monitoring The act of conducting a planned sequence of observations or measurements of control parameters to assess whether a control measure is under control.

Validation Obtaining evidence that a control measure or combination of control measures, if properly implemented, is capable of controlling the hazard to a specified outcome.

Verification The application of methods, procedures, tests, and other evaluations, in addition to monitoring, to determine whether a control measure is or has been operating as intended.

Introduction

Only if you are able to grow or rear your own food do you know exactly where it came from and what has happened to it before you eat it. Few consumers know much about the details of their food, what ingredients it was made from, let alone how it was processed, what benefits or risks it might have for health, or whether it was produced in accordance with religious codes or ethical values.

Food labeling is the key to unlocking information to meet consumers' various and varying needs. Whether living in a fast moving urban metropolis, or a remote community, in a rich or developing country, when purchasing prepackaged foods consumers need accurate food labeling to help make informed food choices – but this can be complicated. Food labeling needs to fulfill many varied functions to meet consumers' information needs, including:

- Who made the food and where?
- How much is in the pack?
- How long will it last?
- Is the food safe to eat as such, or are there any special conditions to follow?
- How should it be prepared, stored, and cooked to meet safety, nutritional, and organoleptic quality?
- Where was the food grown or reared?
- What processing has it undergone and how was it produced?
- What ingredients, additives, and processing aids have been used?
- What nutrients does it contain?
- Are there any restrictions for use, such as not being suitable for babies, young children, or pregnant women?
- Will the food provide any specific health benefits?
- Does it meet religious, moral, and ethical needs?

Food labels also provide food producers with the means to advertise and promote their goods. Exaggerated claims can mislead and confuse consumers about the true nature of the product within the pack, its composition, and particularly its nutritional value.

Legislation has developed over many centuries to protect consumers from misleading information. International food safety and labeling standards are agreed at the Codex Alimentarius Commission and form the backbone for food safety and information for internationally traded foods. Standards are implemented and enforced at the national level. National authorities may adapt food legislation to suit local needs to ensure good food hygiene practices throughout the food chain and to the eventual consumer.

Food safety standards and guidelines, particularly those of the Codex Alimentarius Commission pave the way for good food hygiene – meaning the conditions and measures necessary for the production, processing, storage, and distribution of food designed to ensure a safe, sound, and wholesome product fit for human consumption. Thus, the whole food chain should work to protect consumers and ensure safe food through a process of hazard analysis and critical control point (HACCP) guidance, right through to how the consumer will eventually use the product. Labeling plays an important link in this critical food chain.

 doi:10.1016/B978-0-12-378612-8.00370-X

Producers and manufacturers are required to consider consumer practices in their HACCP plans, especially where the consumer is the final critical control point, for example, where cooking is necessary to ensure safety.

The validation of information on the package, both from a technical perspective, for example, time and temperature of storage and cooking, as well as clarity of the information, is mandatory within HACCP principles. Responsibility for food safety and hygiene can never be fully transferred to consumers. Where the implementation of safety measures by consumers is not feasible, and product safety cannot be assured, the product should not be marketed – it would be unsafe and unethical to pass food hygiene and safety controls directly to consumers.

Food must be safe to eat and will not cause harm to the consumer – when it is prepared and/or eaten according to its intended use. Companies are obliged to clearly identify 'intended use' and make sure that labeling provides the necessary information to consumers to ensure that it is safe, if used according to the 'intended use' instructions.

Food labeling legislation protects consumers but deciphering the complexity of information takes knowledge and determination: many consumers admit to finding difficulty in deciphering food labels and many do not have the time or inclination to pay much attention to food labels. A worldwide online survey of 25 000 consumers carried out in 2012, by market research company Neilson, found that more than half found food labels difficult to decipher.

Truth in Labeling

Ever since food and beverages have been sold, there has been the potential for unscrupulous traders to make 'extra profit' by adulterating, substituting, or diluting expensive ingredients. Foods and ingredients were sold over the counter, often unwrapped. Customers had to make a choice based on what could be seen – the only quality checks were to prod, sniff, or if allowed, to taste; none of which provided much of a guide to the exact composition or provenance of the food, especially not to its safety. The latter was only determined after the food was consumed.

Nowadays with vigilant quality assurance and food inspection checks during processing and producing, the risk of adulteration has been significantly reduced. Compositional standards have been set and quality assurance methods test for contamination. Ingredient listing is expected, as is nutritional information. Yet there is still room for consumers to be misled about the nature and quality of foods offered for sale by clever advertising and marketing. Strict rules about nutrition and health claims have been agreed to combat product hype and help consumers find their way through the complexities. Labeling legislation has a hard job to keep ahead of consumer trends, especially for affluent consumers in developed countries who are concerned about every aspect of their foods and how they were produced.

Consumers have legal rights of redress and protection against foods that are not what they thought they were, or worse, cause a food safety problem, be it foodborne disease or an allergic reaction.

Whatever information is provided on foods presented for sale, be it on the packet or at the point of sale, it must describe the food accurately, must not be false, misleading, or deceptive, or likely to create the wrong or misleading impression about the character of that food, in any respect, and this applies to text and graphs.

This is the fundamental basis of all food legislation be it local, national, or for international food trade – food labeling legislation should deliver foods that consumers can trust to meet their expectations, and importantly eat safely.

When reading this article you might find it helpful to take a look at the food labels in your store cupboard. Find the information that must be present by law, and review the additional voluntary labeling and information presented. Try to assess whether this additional information is essential, helps you make an informed choice, or is merely marketing hype. Evaluate how the information is presented in terms of visibility, for example, is a magnifier needed to read the text and for clarity of the communication, and the legitimacy of the images presented.

Legal Requirements of Food Labeling

There is common and international agreement about the essential information that should be provided on all food labels. These are mandatory in many countries and also for foods traded internationally.

Name

This sounds very basic and not something that needs to be prescribed by law. However, brand or trade names can obscure the true nature of the food, particularly if it is highly processed. Ideally the name of the food should be unambiguous but we have moved a very long way from this with food processing wizardry and marketing hype – especially where there is fierce competition for sales. Consumers can be misled by the name of a food and their gullibility exploited.

What sort of meat is it if it has been packaged, processed, smoked, and reformed? Is it pork or is it something with a fancier brand or trade name? Is it a 'secret formula' drink that looks like fruit juice, but has none in it?

If there is a brand or trade name then in close proximity on the label there should be a clear description of the food, explaining exactly what it is. For example, if it looks like a dairy butter product but has no dairy content, it should be described as something like 'nondairy spread made from a blend of fats and oils.' This description should be in the same field of view, close to the brand name.

In addition, if a product has undergone a processing treatment, such as dehydration, curing, or smoking or been previously frozen and defrosted this must clearly be labeled within the same field of view as the name, so as not to mislead the consumer about the true nature of the food product.

Weight and Volume

Prepackaged foods must declare a weight or volume and in the units of measurement commonly used in the country where they are sold.

Some foods are exempt from the weight declaration, such as a loaf of bread (this can often be prescribed in specific national bread regulations), or where food is sold by quantity – six bread rolls.

Manufacturer or Seller's Details

The name and address of the food business operator that made or sold the product must, by law, be on the label. In the event of any problem the responsible company can be contacted.

Some companies also provide a telephone contact number. It is in the companies' interest to provide direct contact information and the necessary infrastructure so that consumers can contact them in case of a problem. The sooner a problem is reported the faster the company can take corrective actions and contain any problem.

A website address is often provided by larger food business operators where more information can be found about the product, company, production process, recipes, etc. Some companies use such websites for the declaration of allergens. This can be particularly useful for food service establishments as it allows for a detailed, up-to-date investigation of the ingredients in a product, where the packaging has been removed.

Consumers who experience any problem with the safety or quality of food purchased have legal rights of redress from the seller or producer. Local and national food law enforcement responsibilities vary, but essentially customers have the right to complain if the product is not what was expected, or caused any food safety problem.

Instructions for Safe Use

To get the best from any food product it is essential to exactly follow all instructions to ensure the food is prepared, stored, cooked, and served safely.

Foods unsuitable for particular groups, such as babies or the elderly or those with a chronic illness due to the potential food safety risk must be clearly labeled. For example, there is a mandatory requirement to label untreated 'raw' milk. It must be labeled prominently as such, and that it should not be consumed by children, pregnant women, older people, or those who are unwell or have a chronic illness.

Instructions should not make any assumptions about the knowledge or skill of the user and should consider the risk perception of consumers and/or their habits and behaviors, as well as the feasibility of the recommended measures. This should be done through detailed investigation during product and labeling development, by direct surveys with potential consumers of the product. Everything about the product, its preparation, cooking, or storage should be specified to ensure it delivers the safe, quality product that the manufacturer intends and the consumer expects. If food is sold loose, information should be available at the point of sale.

Foods must be labeled with 'any special storage conditions or conditions of use' otherwise there could be an increased risk when eventually eaten. Instructions should include food safety warnings, such as 'once opened keep refrigerated' and 'consume within 3 days of opening,' 'not suitable for freezing,' or if foods are not suitable for reheating or refreezing once thawed.

Because of the increased food safety risk from inadequate or inappropriate cooking or storing, consumers must follow these specific instructions for use, especially for foods that have to be cooked to ensure their safety; instructions for correct storage and cooking can be the last control point in the food chain, to prevent the risk of foodborne diseases. Such labeling or warnings may provide a manufacturer's defense should any subsequent problem occur, nevertheless there can be unforeseen consequences, as some foodborne outbreaks demonstrate.

There have been high-profile cases where confusion, misinterpretation, lack of clear instructions, and a failure to follow instructions have sadly led to major food safety incidents. Raw or undercooked foods can cause serious food safety alerts, such as in the US when raw cookie dough was contaminated with *Escherichia coli* O157 and caused severe renal failure to some 70 consumers. Thorough cooking of the dough would have ensured the cookies were safe to eat, but some consumers were in the habit of eating raw cookie dough (which in this case was contaminated). The manufacturer's label did not specifically communicate the importance of cooking the dough, and not to eat the product raw. After the incident, the label was revised.

Raw chicken nuggets and chicken strips have also been associated with *Salmonella* infections such as in a 1998 Australian outbreak and when stuffed chicken products were implicated in five outbreaks in Minnesota from 1998 to 2008. Consumer confusion regarding whether these products were raw or cooked was documented in the outbreak reports. Products were not clearly labeled as containing raw poultry ingredients; since the products were breaded and prebrowned, consumers were confused and thought that the food had been precooked.

All warnings, including specific food safety control information should be verified by the producer to ensure that they meet food safety standards. For example, cooking the product according to the instructions is essential to ensure that any potential foodborne disease organisms are destroyed and that the food is safe to eat.

All instructions for consumers on the safe use of products, for example, storage temperature and instructions for heating should be validated for both scientific and technical accuracy, as should be the clarity of the communication so that consumers are able to understand the significance of these instructions.

Food safety warnings on labels need to be validated by checking that consumers, typical of those who would use the product, can understand, interpret, and follow the instructions correctly. There are internationally agreed guidelines for the validation of food safety control measures, and food business operators producing high risk foods must ensure appropriate hazard analysis and critical control to ensure consumers' safety from their products.

Minimum Durability or Shelf Life

Consumers should be informed about how long a product will stay fresh and more importantly how long it will remain

safe to eat. The shelf life will depend on the quality of raw ingredients, processing, packaging, and storage. Ultimately shelf life is determined by a combination of microbial, sensory, and chemical methods to ensure that the food is safe, palatable, and acceptable to eat at the end of its shelf life. Consumers are rarely in a position to assess the true shelf life, freshness, or safety of a food product, and must rely on accurate, clear labeling information from the manufacturer.

There is no absolute for the durability of a food product, because at any stage the integrity of the food can be compromised by mishandling. Manufacturers should give consumers best guidance, based on evidence, and stress the importance of complying with storage instructions, especially for perishable food where temperature control is critical.

A range of terms can be found on foods and there are differences worldwide, for example, expiration date, sell by, and use by. There are no internationally agreed terms but in the European Union use-by dates for perishable foods are mandatory. In other countries manufacturers' shelf life labels are advisory and not regulated. Baby and infant formula are required to be labeled with expiration/use-by dates to ensure that the nutritional value has not been compromised.

Best Before

Foods with a long shelf life carry a 'best before' date which is a quality or freshness indicator. 'Best before' dates indicate when foods will be at their freshest and best quality.

If stored correctly, usually in a cool, dry, dark place there is unlikely to be a food safety risk from such foods. Eating foods beyond their 'best before' date means there will inevitably be some deterioration in quality, particularly in taste or texture. Foods where best before labels can be found include dry goods, flour, dried pulses, dry pasta, and dried herbs and spices.

Use By

Highly perishable foods will have a 'use by' warning indicating the date by which the food should be used, when stored according to the instructions. This date should be established based on a rigorous examination of the potential growth of pathogens, and potential safety implications if consumed after that date.

Use by dates are essentially a food safety warning since after that date, even while the food may not have visibly deteriorated or 'gone off,' it could carry a higher risk of foodborne disease.

It is unsafe and unwise to eat foods beyond their 'use by' date and especially so for vulnerable groups including babies and young children, the elderly, and those whose immunity is compromised.

Foods with 'use by' labels can usually only be stored for a few days, such as fresh dairy products or ready prepared meals; they will also need to be kept refrigerated and the temperature should be specified.

Some foods such as fruit and vegetables, which are intended to be used fresh may not have a date mark; it is assumed that such foods will be eaten shortly after purchase, while still visibly fresh.

Manufacturers and retailers may put additional dates, such as 'display until' on some foods: these are for stock control purposes and consumers should always refer to the 'use by' date for safe use.

Storage

When offered for sale, be it at a market stall, street vendor, or supermarket – food must be safe to eat. Once purchased, whether sold loose or prepackaged, consumers must store food as instructed, to ensure it remains safe until consumed.

Storage and transport instructions must be specified to maintain food safety and quality. Correct and precise information about where to store a food, at what temperature, and for how long, before and after the pack has been opened must be given. The importance of following storage instructions for consumers can be illustrated by the botulism case linked to refrigerated carrot juice, which occurred in the US and Canada in 2006. The implicated products were pasteurized but were not heated to a temperature that would eliminate spores of proteolytic (the most heat-resistant type) *Clostridium botulinum*. Subsequent testing of leftover carrot juice recovered from the home of one of the affected persons found botulinum toxin in the juice. The carrot juice products involved in these illness cases were distributed under refrigeration, and were labeled with one or more of the following statements 'Keep Chilled,' 'Keep Refrigerated,' 'Perishable Keep Refrigerated,' or 'Extremely Perishable Keep Refrigerated.' Because proteolytic *C. botulinum* spores are known to grow and produce toxin only when there is severe temperature abuse, it was suspected that this particular juice may have been left unrefrigerated for an extended period, either during distribution, or once purchased by consumers, thus allowing *C. botulinum* spores to grow and produce toxin.

There is great confusion over where and how long to store foods yet this is crucial information. A good clue to storage at home is to store food as it was stored at the point of purchase – be it in the freezer, fridge, or at ambient shelf temperature.

Preparation

Prepackaged foods that are 'ready to eat' and do not undergo further safety treatment, such as cooking, should be safe to eat at the point of sale.

Prepacked food that is to be further prepared and cooked should have clear instructions about how to render it safe and/or maintain its integrity and safety until eaten. Instructions about how to prepare food should be explicit, for example, does the food need to be washed? What further preparation is necessary? Are there any special instructions to follow for safe food preparation to avoid cross contamination? This is especially important because no fresh foods are sterile and high risk foods always pose an increased risk of cross contamination and subsequent foodborne diseases from incorrectly prepared foods.

Workers in food production and food service have to undertake a 'Food Hygiene Training Course,' which ideally should be a mandatory requirement. Such courses stress the rules of basic food hygiene, how to avoid cross contamination, how to store and cook food safely to the correct temperatures. Domestic consumers may be unaware of the importance of good food hygiene and how to keep food safe and to prevent a foodborne disease, hence the need to have clear precise

information, instructions and where appropriate warnings on all food labels.

Foods which naturally contain bacteria, such as minced meats and chicken must be treated carefully during preparation to ensure there is no cross contamination to other foods, particularly ready cooked foods, such as meats and dairy products, which should always be stored separately. Good food hygiene practices are essential to reduce the risk of cross contamination.

Cooking

Cooking instructions should give the cooking temperature and time to ensure that the food is served safely and at its best: there should be no risk of a foodborne disease however the food is to be cooked.

When using different appliances the variations in time and temperature can be considerable and specific details should be given for each method.

It is important to ensure that food is cooked according to the correct instructions, not only for it to look and taste good but also to ensure that it is safe to eat. Some foods need thorough cooking to destroy any potentially harmful bacteria they may contain: this is particularly important for chicken, ready or preprepared meals, and eggs.

For some foods cooking is the final stage of food safety control to ensure food safety. Consumers must follow instructions to ensure that this control point is carried out as required. Food business must validate instructions and ensure that this final control measure is clear and easy to follow.

Providing clear instructions can be a due diligence defense should any subsequent foodborne disease occur through incorrect cooking. Specifically to reduce the hazard of *Salmonella* found in eggs, labeling is the final control measure among several, beginning on-farm right through to storage and use by the consumer: correct cooking will ensure safety against contamination of the raw egg. Raw eggs can pose a high risk to consumers, and particularly to vulnerable groups, specific warnings must be given on the label – Do not eat raw – Cook thoroughly until hard – Do not eat soft boiled eggs. Thorough cooking is necessary to destroy any potential food hazards, likewise for minced beef, which can be susceptible to contamination with *E. coli* and if not cooked correctly can cause severe renal problems and death in children.

Raw, ready to cook foods have been identified as the cause of several foodborne disease outbreaks. For example, in the US in 2007 'pot pies' caused a foodborne disease outbreak from *Salmonella*, and similarly frozen, not-ready-to-eat microwavable meals have been implicated in other salmonellosis outbreaks. The pot pies associated with this outbreak had a raw flour crust and were 'not-ready-to-eat.' Consumers could cook according to their preference. Even so, consumers were required to ensure that minimum cooking temperatures were reached to control microbiological hazards. In addition, because raw frozen poultry pastes had been used to make the liquid portion of the chicken and turkey pie fillings, the pies might have contained undercooked poultry, or been cross contaminated from these raw poultry pastes, which often harbor *Salmonella*. This outbreak report identified labeling concerns, specifically, recommended microwave cooking times on the pot pie packaging were based on wattage categories, but most consumers (who became patients) were unaware of microwave wattage. In this case improper microwave cooking could not account for the entire outbreak, however, given the limited knowledge of consumers about microwave wattage, and the frequency of deviating from microwaving instructions, microwaving probably led to inadequate cooking.

Inadequate microwave cooking has been thought partly responsible for other previous outbreaks of *Salmonella* infections. Industry and regulators should consider examining the manufacturing processes for frozen not-ready-to-eat foods to determine the extent to which microwave cooking is safe for these products. Labeling and cooking instructions on 'not-ready-to-eat' frozen foods should be clear to ensure that consumers are aware of health risks, and to facilitate compliance with validated cooking methods.

Clear and prominent listing of output wattage on microwave appliances might improve consumer adherence to manufacturer's cooking instructions. Consumers should follow cooking instructions specific for an oven's wattage.

Although often foods designed to be cooked in a microwave oven will give a warning to follow the specific wattage of the oven being used, many consumers, as noted above, are unaware of the wattage of their appliances. And even this instruction is no guarantee of correct heating. The only accurate way to ensure that the correct internal temperature has been reached is to use a food thermometer. Although these are common in food service, they are not so common in domestic situations.

Given the limited use of food thermometer in the home, some manufacturers use specific instructions on microwave foods, particularly to cook foods until 'piping hot throughout,' with instructions to stir during cooking, and to allow standing time to equalize the temperature throughout before serving. This is very important because hot and cold spots can hide, especially in frozen or chilled foods; the whole food product must reach the required high temperature. 'Piping hot' is not a specified temperature and can be ambiguous, but it provides general advice for consumers to ensure that a high enough temperature has been reached.

If the product needs to be defrosted before cooking, this instruction must be followed to ensure safe time–temperatures are reached during cooking.

The importance of correct cooking temperatures cannot be underestimated for food safety. All of this information and instruction seems obvious. Often, the specific details can be overlooked or ignored and consequently can contribute to foodborne illness if cooking temperatures have not been high enough to destroy harmful microorganisms that can cause foodborne diseases.

Composition

A list of all ingredients and additives must be declared in descending weight order under the heading 'Ingredients.'

Compositional standards for some staple products are prescribed in national regulations, but increasingly these have been withdrawn.

The quantity of the main ingredients must be declared when featured in the name of a product: a quantitative

ingredient declaration. This enables customers to make an informed value for money choice and compare products, such as beef burgers, to find the percentage of the key ingredients in similar products.

When listing smaller amounts of food ingredients there are many specific labeling standards and guidelines about how these should be labeled to ensure consistency and convenience, for shoppers and producers alike. It can be impractical to label every specific addition by its chemical name, yet a full declaration needs to be made to ensure that consumers can make appropriate choices; especially if they wish to avoid certain additives or ingredients due to allergies or hypersensitivity. Any product which has been made from biotechnology (or genetic modification (GM)) where there is any likelihood of transfer of an allergen must be labeled.

Permitted food additives must be declared, generally according to their function, such as color or emulsifier, and/or according to their specified name or classification, such as 'e' numbers within the European Union or the Codex International Numbering System for foods traded internationally. Functional classes include a long list of generic terms, such as flavor enhancers and sweeteners, and processing aids such as antioxidants, firming agents, and stabilizers, and the generic term can be used.

Compound ingredients should also declare ingredients (in brackets) after the main name. Any food additives in a compound ingredient must be specified in the full ingredients list.

When making declarations of ingredients some shortcuts to the full names and groups of ingredients are permitted, by the use of 'general class names.' For example, refined oils and fats of any type can be labeled in the ingredients list as 'oil' or 'fat,' likewise for 'starches' and 'sugars.' However, because foods, such as pork or beef, are prohibited in religious dietary rules they must always be specifically declared on the label, including pork or beef fat.

Added water should always be declared in the list of ingredients. Added water resulting from processing must be declared with its percentage, alongside the name of the product, for example, ham with 10% added water.

Hypersensitivity and Allergens

Some food ingredients and additives are known to cause hypersensitivity and an allergic reaction and should always be declared, especially if included as part of a compound ingredient. The list includes gluten containing cereals, crustacean, eggs, fish, peanuts, milk, etc. This list is regularly reviewed as more evidence emerges. National food control authorities keep a full list updated and published for food business to provide consumers with the most up-to-date information about ingredients that may cause a hypersensitive reaction.

National regulations may require more specific warnings where there is a particular risk or high level of sensitivity in a population group, such as, for peanuts where there is a high risk of an anaphylactic shock reaction.

High risk foods that could cause hypersensitivity and/or an allergic reaction must be labeled with a clear warning, such as – contains nuts, contains sulfites, according to the specific current list of foods that can cause hypersensitivity.

Origin

The place of origin must be declared, particularly if not doing so would deceive or confuse the consumer.

Consumers like to know where their food has been sourced, and many wish to support local or national producers, or alternatively boycott foods from certain countries for political, moral, or perceived food safety problems such as during the bovine spongiform encephalopathy epidemic in the UK and Europe.

Origin labeling is increasingly used to inform purchases. There must be a clear declaration of the country or region where the food originated, and where any additional processing or packaging occurred. National flags or logos can often be used in addition to identify the country of origin.

Within Europe there are three additional specific 'origin' labeling schemes. These ensure that food products genuinely produced in that region are protected, the name is protected for that food alone, and this is clearly and distinctly labeled. Thus protected designation of origin, protected geographical indication, and traditional specialty guaranteed labels are regulated and increasingly known in Europe and beyond. While originally devised to protect the reputation of the regional foods and help producers obtain a premium price (by eliminating unfair competition), nowadays these schemes are useful shortcuts for consumers seeking out genuine products, produced in specific areas, to specific quality standards and flavors. Protected names include Champagne and Roquefort cheese from France, Melton Mowbray pork pies from England, and Parma ham from Italy.

Clarity and Readability

It is self evident that food labels need to be clear and easily readable. Food regulations have evolved to set standards for clarity to guide producers and to meet consumers' needs.

Initially there were different voluntary schemes about the format of labeling information and differing codes of practice developed, but gradually harmonization is emerging at national and international levels. This is much appreciated because many consumers, and especially older people, complain about the clarity of labels, the small size of text, and difficult to read colors and fonts.

Wherever a product is sold the label must be written in the main language spoken – some internationally traded foods can have several different panels for different languages but they can often be so small that whether they can be read by anyone anywhere is doubtful.

A minimum size font is necessary for all food labels – there is no point in providing all the labeling information if it is too small to be read easily. Specifications are being agreed in Europe to ensure readability and clarity through the European Food Information for Consumers Regulations, due to be implemented at the end of 2014. Further guidance on clarity, visibility, and indelibility of labels will be provided.

Claims

Food labels provide an ideal mechanism for advertising and promoting the benefits of a particular food, ingredient, or

nutrient. As such all manner of claims evolved to promote special benefits. The validity of many claims was in question and it was impossible for consumers to ascertain the true nature and properties of the food. Regulation of such claims has become necessary because consumers were undoubtedly being confused and misled.

Nutritional content, functional and health claims are now highly regulated at the international level by Codex Alimentarius, the international standards setting body. Many national authorities follow the Codex guidelines on claims and transpose these into national regulations, but there can be considerable national variations and specific requirements for additional information and presentation formats to meet the specific needs of populations.

As a general principle nutrition and health claims must be consistent with national nutrition policies, be supported and validated with sound evidence, provide truthful and nonmisleading information to help consumers choose a healthful diet.

There are specific detailed regulations and guidelines for the main categories of regulated claims – nutrition declaration and nutrition, comparative, and health claims: these categories are briefly outlined below. Specific rules apply in different national legislation and should be consulted for more detailed reference and current requirements.

Nutrition Claims

Nutrient Function

For each nutrient a function that describes the physiological role of the nutrient in growth, development, and normal functions of the body is prescribed. These claims can be simply stated as the physiological role of a nutrient in the body and that the food is a source of or is high in that particular nutrient.

Nutrient Content

A nutrient content claim is a nutrition claim that describes the level of a nutrient contained in a food, such as, 'source of calcium' and 'low in fat.' Reference levels at which a content claim can be used are specified in international and national legislations. For example, to make a claim of low fat, the table of conditions for nutrient content claims applies. In this context it means that not more than 3 g fat per 100 g solids can be present. For each nutrient content claim the conditions are strictly prescribed.

Nutrient Declaration

If any type of nutrition claim is made on a food label, be it for the function of a nutrient, presence or absence of a nutrient in the food, or for the product or ingredients' health benefit then a nutritional declaration must be made.

The main nutrient groups to be declared are generally for energy, fat including saturates, carbohydrates, sugars, protein, and salt. Exactly how the declaration is made varies considerably between countries and could be presented as a list, a detailed nutrition panel, or a table, with legal specifications for how each nutrient should be declared, the unit to be used, along with specifications about per portion or per 100 g.

In some cases there is national guidance about how this information should be displayed, the format, and whether this should be on the front of the pack to guide food choice, by a pictorial representation, pie chart, or traffic light representation for each nutrient. In some countries voluntary codes have been agreed with the food industry to declare daily guideline amounts of nutrients and comparisons are made for a portion of the food and its contribution to the daily guideline amounts for specified nutrients.

Comparative Claims

A nutrient comparative claim compares the nutrient levels and/or energy value of two or more foods and will claim, for example, to be 'reduced fat' and 'less than.' The comparative food should always be declared.

Health Claims

Health claims are only allowed on a permitted basis, and on condition that they meet specific strict conditions, particularly for substantiation and proof of a positive effect on health. A health claim means any representation that states, suggests, or implies that a relationship exists between a food or a constituent of that food and health. Claims that imply they could prevent, cure, or treat a disease are prohibited.

The legal requirements permitting regulated health claims have significantly reduced the number of spurious, ambiguous health claims: consumers should now be more confident about the particular health benefits a food can confer, as part of a normal diet, and be better able to assess whether a particular health claim would be beneficial to their individual dietary and health needs.

The conditions that apply to health claims are detailed, and vary between countries, but essentially health claims must ensure that the claimed benefit is significant and appropriate for the population group being targeted and also available from eating normal quantities of the foods in the diet.

Health claims must be scientifically validated by the competent national authority and be relevant for the target population group.

Prohibited Claims

The following claims in the labeling or advertising of a food are prohibited – a claim that a food has tonic properties or that it has the property of preventing, treating, or curing a human disease.

Permitted Claims

Some claims relating to foods for particular nutritional uses are permitted but are very specifically regulated, such as for infants and baby foods, or those for particular nutritional use or population groups.

Misleading Claims

Some terms, logos, brand names, and pictures on food labels and advertisements can be misleading, and some maybe even deliberately so. When a product shows an idyllic country scene with cows grazing in green fields and hens being fed by the

farmer's wife, the expectation is that the product was made from animals reared under those same conditions – this is rarely the case given that most foods, including animal products, are likely to be mass produced, maybe under conditions more like a factory than the rural idyll of bygone eras.

Terms such as healthy, natural, farm fresh, freshly made, are meaningless and should not be used unless specific validation and explanation is given. These terms are often marketing hype: many are now prohibited in national regulations.

Additional Labeling for Consumers

Legal labeling requirements fulfill consumers' essential information needs but increasingly as food production becomes more sophisticated and prepackaged food more complex. Sometimes more information is needed and certainly much more is provided than most consumers ever read when making a purchase. This information is provided on a voluntary basis and, as such, there are no internationally agreed standards or guidelines. Notwithstanding this the general tenet that food labeling should not be misleading still applies.

Many consumers seek particular information to meet their individual health, religious, lifestyle, ethical, or moral needs and the sections that follow outline the particular categories of such additional information provided on food labels.

Religious Dietary Codes

Religious food codes and rules are strictly adhered and consequently methods of production, particularly slaughter, are strictly controlled, particularly for Halal and Kosher foods. Certain foods, ingredients, and production methods are prohibited and conformity to the rules usually overseen by the religious authorities. Products are certified to guarantee compliance to the strict dietary rules, and both Kosher and Halal foods are thus guaranteed worldwide for Jewish and Islamic followers, respectively.

Some labeling terms can cause particular concern and ambiguity for those trying to avoid certain animal products. For example, use of the term gelatin does not specify from which animal it was produced – be it beef or pork. More specific detail is essential for those who wish to follow Halal and Kosher dietary laws.

Vegetarian

The term nonvegetarian is applied to foods made from or with products derived from animals, for example, red meat, poultry, game, fish, shellfish, and other seafood.

To conform to religious and/or moral codes, the eating of meat, poultry, fish, and/or animal products such as milk, dairy, cheese, and eggs is restricted in the diets of many groups. Hindus maintain a strict vegetarian diet often eating no animal produce whatsoever, restricting especially beef and eggs. Others might refrain from eating meat and poultry for health or moral reasons yet still accept animal produce such as milk and eggs.

Dietary rules about what can and cannot be eaten are varied and yet precise. For this reason declarations and definitions of 'vegetarian' and 'vegan' vary between different cultures. While ingredient listings is a legal requirement, this puts the onus on consumers to check that the food is acceptable To help those wishing to avoid animal produce, many variations of labels and logos announcing 'suitable for vegetarians' can be found. Other labels and logos specify 'no beef' or 'no pork' to meet specific Hindu and Muslim dietary requirements, respectively.

The term vegetarian can mean different things to different cultures. For example, the acceptability of eggs as part of a vegetarian diet for some is contrary to others, especially Hindus. Hence, for this reason there is no internationally agreed definition of vegetarian. In some cultures the term vegan is familiar to denote free from any animal or animal derived products, but in other cultures this term is unfamiliar.

Consumers who have dietary restrictions are always advised to check the ingredients list and not to presume that logos or labels of 'vegetarian' will meet their particular needs.

Negative Labeling 'Free From'

Those with particular dietary needs are catered for by premium special ranges often sold and marketed as 'free from.' These can include wheat and gluten for celiac sufferers, sugar free for diabetics, or dairy free for lactose intolerance.

Regarding allergens or ingredients that might cause hypersensitivity guaranteeing that a product is 'free from' must be absolute. Product specifications and manufacturing processes must be accurate because there could be liability for any illness or reaction experienced from cross contamination. In general it is better not to make such claims for allergens because there can always be the risk of cross contamination, which could give a false sense of security to the customer. If there is any possibility that the product could be contaminated with an allergen then consumers must be warned to this effect and it is more common to see such allergen warnings on labels.

'Free from' products that guarantee to be free from an allergen are generally much more expensive as a result of the additional quality assurance to deliver the claim.

In addition, some food processing techniques are controversial and there have been calls for negative labeling, such as 'free from' or 'contains no' genetically engineered organisms, hormones to increase milk production, monosodium glutamate. Although such claims are not specifically regulated, they should all be verifiable and conform to the general principle of food labeling, which is not to mislead the consumers.

May Contain

Where a manufacturer cannot guarantee the absence of ingredients, such as peanuts, which might inadvertently cause an allergic and life threatening anaphylactic reaction, a 'may contain' warning should be given on the label – 'may contain nuts.' Sometimes wording such as 'made on the same

processing line as…' is used to better inform susceptible consumers of the potential risks.

Although every effort is made to ensure that cross contamination does not occur with high risk foods or ingredients during production, in some cases this cannot be guaranteed: For example, during chocolate or biscuit manufacture where nuts are used for other products manufactured in the same factory. Manufacturers may prefer to make the positive declaration that the product may contain (say nuts or a potential allergen) to warn susceptible consumers of the risk from cross contamination during production.

Production and Processing

How food and ingredients have been produced is of keen interest to some consumers who wish to make particular purchasing choices, often associated with meat and animal products, but not exclusively.

Many food claims and labels about food production cause confusion, but there are specific regulations and labeling prescriptions for some methods of production, usually those wishing to differentiate and command a premium price in the marketplace. For other newer techniques food labeling lags behind the technology and there is fierce debate about whether or not mandatory labeling should be provided. All novel foods and processes are scrutinized and approved to ensure the foods are safe to eat but consumers should have the right to full and accurate information to make an informed choice about the foods offered for sale.

Although labeling legislation will never be able to keep ahead of new technologies, consumer groups insist that it is a fundamental right to have full declaration of all such new technologies, especially novel processing techniques such as those produced from genetic modification, biotechnology, or nanotechnology – these have yet to be appropriately labeled for some consumers: Without the basic tenet of full declaration and truth in labels the consumer could be misled or worse deceived about the true nature of foods and their production methods.

Many voluntary, private labeling schemes have evolved to meet consumers' needs for specific information about production processes: these can address particular, legitimate consumer concerns, such as animal welfare, environment, eco credentials, hormone free, etc.

Few production standards and claims are regulated, but organic food production and Halal food labeling are examples where there is international agreement to labeling and production standards.

Organic

Within international food trade, certain production methods now have clearly defined standards of what can and cannot be done during production and processing and specific rules of how this can be labeled. Notable is organic (biological or bio) food production which is internationally regulated under Codex Standards because much organic food is traded internationally. These production and labeling standards provide the common baseline for trade. Private or national standards can make specific additional requirements over and above internationally recognized standards and guidelines.

Organic food production differentiates itself from more mass food production by limiting specific inputs to the soil and animal treatments. The certification and labeling of organic food and ingredients is highly regulated. Such products are certified as organic by regular inspection and certification or licensing of producers.

Organic labeling requirements are specific and need to include a regulated organic logo and a declaration of organic certifier.

Free Range

The rearing practices for food animals and their products can vary drastically and consequently have very different costs of production and welfare implications. Being able to differentiate premium production standards and premium products from imitations is essential for consumers and producers alike.

Free range eggs are a classic example – how does a consumer know if an egg came from a chicken able to roam freely, or from one confined to a battery cage? Consequently production methods and labeling regulations for eggs are regulated and marketing terms have to a large extent been simplified to help consumers in their choices.

There has been a backlash against intensive 'battery' egg production methods and battery egg cages have been banned in some countries. Eggs are still produced from caged birds but where there is more room for the chickens to move around, some have 'enriched environments' with more room to roam. Production methods dictate costs yet it is impossible at point of sale for consumers to detect a visual difference.

Much emphasis is placed on egg production standards and assurance schemes, which are regularly inspected. Clear definition for labeling ensures that consumers are aware of how eggs have been produced, be it free range or from caged birds.

Formed or Reformed Meat

Meat is often the most expensive food and many different quality manufactured products are available. Where meat is formed from prime cuts or reformed into 'authentic' looking joints of meat, food labels must make clear that this has taken place. Clear descriptions using the terms formed or reformed should be used on the front of the pack, in the same field of vision as the name of the product, such as ham made from formed cuts of pork.

Irradiated

Any food or ingredient that has been treated with ionizing radiation should, by law, be labeled and additionally can carry the internationally recognized logo (see **Figure 1**). Such a declaration should always be made next to the name of the food or ingredient even when a small part of a compound ingredient – there is no exception to this labeling requirement for food traded internationally.

Genetically Modified

Foods and food ingredients made through the process of biotechnology, with genetic material from another species, have gradually been introduced to the marketplace in some countries, whereas in other countries they are yet unfamiliar: their labeling has proved controversial.

Figure 1 Internationally recognized irradiated food logo.

Food ingredients and processing aids such as enzymes and yeast have been modified but no labeling declaration to this effect is mandatory.

Consumers have legitimate rights to be able to make an informed choice about their foods and to make a selection according to their own particular needs. Argument continues about GM or biotechnology – are the products same as those conventionally produced and therefore need no labeling or is this such a fundamental difference that by law all such foods and ingredients should be labeled? The jury is out on this matter.

There is international agreement that should a product carry any new material that is likely to cause hypersensitivity when transferred to a product that previously did not have this genetic material, then mandatorily it must be labeled.

Alcohol

The labeling of alcoholic drinks is relatively new. Familiar alcoholic drinks were originally sold on their brand name with emphasis on secret, age-old recipes, and until relatively recently in France ingredients listing for wine was not permitted, but things are changing, particularly in Europe.

The amount and percentage of alcohol must always be declared and in many countries this was initially introduced as a means of taxation. Consumer information about units of alcohol and safe levels to drink are relatively recent and still vary considerably from country to country, and can be voluntarily agreed with the drinks industry.

There are several important reasons to label alcoholic drinks: for the payment of duty, to protect those who may have a hypersensitivity to common ingredients such as sulfites, to indicate the strength of alcohol in the drink, and to give public health messages.

In some countries warning 'not to drink when pregnant' are prominent and in others, vague statements to 'drink responsibly or sensibly' are required.

Private Labeling Schemes

Retailers, trade bodies, environment groups, assurance, certification bodies, and consumer lobby groups can set up their own voluntary schemes according to their own particular criteria, be it for food safety, animal welfare, environment, fair trade, or food chain assurance. There are probably hundreds of such schemes worldwide.

Each private scheme will have its own standards and methods of verification, ideally with clear published information for consumers explaining how the scheme is managed, how standards are determined and assured.

Most often there will be a unique trade mark or logo which is the main marketing tool for consumers to identify foods belonging to a particular scheme. Each scheme will market and promote its own 'brand' and the consumer logo, according to its own rules.

The myriad of private label schemes tend to follow and also tap into current consumer trends be it for eco-labels, sustainable production, residue free foods, pest management, animal welfare, social responsibility, fair trade, or GM free products. Industry private schemes for meat, poultry, or vegetables tend to set quality assurance and standards for production.

Private label schemes can be an important shortcut and guide to making appropriate food choices and can have considerable loyalty amongst consumers. However, it is crucial for consumers to interrogate each scheme's detailed information, standards, and whether or not there is independent verification of the claims by appropriate certification schemes to ensure that expectations are actually delivered. Private label schemes are not controlled by the national food authorities, they are voluntary schemes managed by their own boards and standards setting body.

Concerned consumers will need to interrogate the specific criteria for each private labeling scheme to ensure that it meets their particular needs, rather than presuming that these claims deliver all that they imply.

Welfare Friendly

Animal welfare in some cultures is a major concern and ensuring that animals reared for food are treated well during their life and, at time of slaughter is a particular concern. This includes how the animal was fed, reared, whether it was allowed to display its natural behavior, with the right to roam or forage, or if it was restricted, being more confined and 'factory farmed.'

Differentiation in the marketplace is important and consumers are often willing to pay extra for foods that have been produced to higher welfare standards, but how those standards are set and enforced needs to be considered when making this choice.

To meet this legitimate consumer demand many schemes have been developed, each with their own specific parameters to meet different cultural and moral requirements: terms such as higher welfare, cruelty free, naturally reared, free range, outdoor reared, etc. Likewise for other labeling schemes such as dolphin friendly, quality assured.

Animal welfare schemes and labels are not defined in food law, but the basic rule of food labeling applies – that the product must be described accurately, must not be false, misleading, or deceptive, or likely to create the wrong or misleading impression about the character of that food.

Eco or Sustainability

Knowing where food has come from and how its production has impacted the environment is of keen interest for some consumers: food labeling and information has responded and many private schemes address issues of food miles, rainforest friendly, green, and sustainable production.

Exported Foods

Foods have always been traded from one side of the globe to the other, and all places in-between, many are prepackaged or will end up as ingredients in packaged foods.

Wherever the food is eventually sold there must be assurance that it is safe, and that it is accurately labeled.

It is mandatory to ensure that food labels are displayed in the main language of the country where it is sold. Some foods have labels in several languages to meet this requirement; others can have the essential legal information translated and be overstuck with a translated label to meet this requirement.

All exported and imported foods must meet minimum food safety standards. There are strict food safety and production standards at the national, regional, and international levels, as well as product-specific standards of quality and composition. The Codex Alimentarius Commission is the international food standards body where member countries agree on standards and guidelines for international food trade, to ensure it is safe and that, providing the Codex standards are followed there should be no barrier to trade for exported foods.

Eating Out

As eating away from home, be it at work, socially, or 'on the move' becomes ever more widespread, consumers with particular needs will also need particular information when eating out, to ensure their health and dietary codes are met.

Restaurant menus will of course give a detailed description of the food served, but detailed ingredient lists are not usually available. Claims are more about the flavor and quality of the final dish rather than about specific ingredients, the health and nutritional qualities of the food, or the allergens it might contain.

There are moves to introduce more specific labeling and information for consumers where there is no choice of food – on the move – for example, on airline foods especially for long distance flights. Here specific details of what is included or not are needed to meet the needs of different religious and cultural codes for consumers traveling beyond familiar territory.

Fraudulent practices where cheaper, substandard ingredients or worse, stale or contaminated foods are served are illegal. But it is difficult for consumers to tell exactly what is in foods served when eating away from home. Although there have been campaigns for 'truth in menu' to confirm exactly what is being served, such as the type of meat, for the most part the rule of '*caveat emptor*' – buyer beware – is paramount when eating out.

Quality Assurance

Traceability

Many of our commonly used foods contain an infinite number of ingredients from all over the world: international food trade is the norm, especially for commodities such as meats, cereals, fruits, vegetables, herbs, and spices.

Traceability of ingredients and food batches is essential with such extensive global and national food trade: manufacturers need to know exactly where and when a particular batch or lot was produced, and will label it accordingly. These batch or lot numbers are often indecipherable codes for consumers, but they contain key information for producers and retailers.

Should a subsequent problem arise, be it a food safety alert or be it from contamination with a foreign body, foodborne disease, or even a rouge ingredient that could cause hypersensitivity, then being able to trace a specific batch or lot of food by its unique number is essential for the effective and safe recall of the product.

Consumers can be alerted to such food recalls by national food agencies and also by retailers and manufacturers.

Quality Control

With keen emphasis on food safety, hazard analysis, and control at every stage of production, processing, manufacture, and retail, and with vigorous quality assurance, food business operators should be confident that the food products they offer for sale are safe. Yet as we know, problems are identified – through human error, manufacturing defects, and the like.

International and national rapid food safety alert systems can swing into action to withdraw suspect foods from sale, and recall any that have already been sold.

Some multinational retailers with sophisticated customer loyalty schemes can identify exactly who has bought the offending products from the scanning of the product bar code, at point of purchase, to pin point batch details and customers' receipt information. It is even possible to contact customers directly to alert them of the problem. This is truly comprehensive traceability from farm to fork, and something that goes on behind the scenes, to protect customers who remain oblivious, unless of course there happens to be a problem.

Much information can be obtained from manufacturers' bar codes, where pricing information can be scanned at point of sale, and stock control monitored.

Additional Information Provision

Many foods will now display contact details, for additional information sources, be it a website address for the producer, manufacturer, retailer or the food brand, or an internet, social media campaign.

Website information can be a very useful source of additional information, but it does not replace the need for clear, legally compliant information on labels: Obviously much more information can be provided on the internet.

For consumers who have particular dietary or food safety needs brand websites are a useful way of checking that a product meets specific needs and many manufacturers will disclose more information about their products for groups with health conditions such as celiac, diabetic, or those with particular hypersensitivities, especially to nuts. This is invaluable additional information and assurance for these particular groups of consumers.

Websites can give customers assurance about production methods, how ingredients were sourced or animals reared. Such is the thirst for knowledge from some consumers about particular moral issues, such as about meat production and animal welfare that live web cameras on farm, and at slaughterhouses, can also be provided via dedicated websites.

Food businesses now actively encourage customers to engage with them via social media and indeed this is now a significant way of advertising new food products through 'Facebook,' 'Twitter,' and the like. Major food brands encourage 'followers' and are then able to target advertising more closely to customers' likes and dislikes.

With new media it is likely that the Internet will become an important additional source of information but it does and cannot replace the legal requirement to provide accurate and informative food labels.

Disclaimer

This article is a general overview of food labeling and information for consumers: it is not a definitive legal guide.

National regulations vary: Food business operators, to meet their legal obligations, should seek formal legal advice about current applicable labeling requirements from the relevant national food authority.

FOOD SAFETY ASSURANCE SYSTEMS

Audits of Food Safety Management Systems

Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland
S Mortimore, Land O'Lakes, Inc., St. Paul, MN, USA

Glossary

Adulteration A fraudulent action that is intended to: (i) omit a valuable constituent or substitute another substance, in whole or in part, for a valuable constituent; (ii) conceal damage or inferiority in any manner; or (iii) add any substance to increase its bulk or weight, reduce its quality or strength, or make it appear bigger or of greater value than it is.

Audit A systematic and functionally independent examination to determine whether activities and related results comply with planned objectivities.

Benchmark A reference point or standard against which performance or achievements can be assessed. A benchmark refers to the performance that has been achieved in the recent past by other comparable organizations, or what can be reasonably inferred to have been achieved in the circumstances.

Compliance The products and/or practices meet regulatory requirements (to be differentiated from conformity which means that activities are carried out according to the established procedures).

Control measure Any action and activity that can be used to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Corporate governance A system of law and sound approaches by which corporations are directed and controlled, focusing on the internal and external corporate structures, with the intention of monitoring the actions of the management and directors and thereby mitigating agency risks which may stem from the misdeeds of corporate officers.

Critical control point (CCP) A step at which control can be applied and is essential to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

Good hygienic practice A system of management controls that need to be adopted at production, processing, storage, distribution, and preparation to ensure safety and suitability of products of consumption.

Hazard analysis and critical control point (HACCP) system A preventive system which identifies, evaluates, and controls hazards which are significant for food safety.

Validation Obtaining evidence that a control measure or combination of control measures, if properly implemented, is capable of controlling the hazard to a specified outcome.

Verification The application of methods, procedures, tests and other evaluations, in addition to monitoring, to determine whether a control measure is or has been operating as intended.

Introduction

Audits (food safety audits) refer to an industry activity to verify that the food safety management system is implemented correctly and effectively, and is maintained. The primary reason for auditing food safety management systems is to establish whether a food business has the ability to consistently produce, manufacture, or distribute 'safe' food and to ascertain that the food safety management provides adequate assurance. Audits may be carried out by a business itself as part of self-control in which case the audit is called internal audits. It can also be carried out by an external body such as the customer or a certification body, which is then referred to as 'third party audit.'

In the framework of the enforcement of laws and regulations, governmental authorities also verify the compliance of industry practices with laws and regulatory requirements. This activity is usually referred to as 'inspection.' Today, inspections follow a similar process as audits and have become very comprehensive; although they are carried out for a different purpose. For a more thorough review of inspection, the readers are referred to a specific article on this subject. The focus of this article is on the industry audit of the food safety management systems.

Definition and Purpose

An audit is an evaluation to verify that actual practices match set standards and codes and determine gaps, if any. With advances of the hazard analysis and critical control point (HACCP) system and the integrated food safety management system, the scope and purpose of audits in the industry have shifted from a snapshot examination of good hygienic and manufacturing practices to a more general audit of the food safety management systems. Thus, the primary purpose of audits is no longer for controlling hazards, but for confirming that control/preventive measures are implemented correctly and are effective.

 doi:10.1016/B978-0-12-378612-8.00368-1

However, there are multiples reasons for which audits may be carried out. These include:

1. Confirming the compliance (or identifying the divergence) with the internal rules and/or regulatory requirements. This is perhaps one of the most frequent objectives of audits.
2. Evaluating the ability of a supplier or a contractor to produce, manufacture, or transport a food according to the set requirements. This can happen when choosing a supplier, a contract manufacturer, or even purchasing a new business.
3. Investigating violations or incidents, for example, investigating a recurring critical control point-related violation, employee complaints, alerts by internal whistleblowers, frequent consumer complaints, or a full-fledged incident.
4. Obtaining a certificate of assurance for the customers that their requirements are met. This may be with customers nationally or internationally.
5. Benchmarking or analyzing gaps in view of identifying the need for improvement, including the need for technical assistance, training and guidance on competences, and/or improving the infrastructure (equipment, design of premises), etc. This can happen when a new factory or business is purchased, or when companies are merged. Experience has shown that small- or medium-size businesses are often not resourceful enough to know the regulations that they often learn about these when they are visited by an inspector or assessed by a customer or the representative of a certification body. In such a situation, to avoid conflict of interest it is important that those involved in guiding the business are not the same individuals who will also assess for compliance.

Scope and Frequency of Audits

The scope and content of audits have also evolved with time. Some years ago, depending on the stage of the food chain, such audits were limited to verifying compliance with good fishery, agriculture, farming, manufacturing, transport, or hygienic practices. Later, they were developed to include audit of HACCP. Today, with the advance of an integrated approach to food safety management, particularly the development of ISO 22 000, audits include a variety of elements, such as:

1. Management commitment, organizational structure, corporate governance and its impartiality and resources.
2. Management of people (including training).
3. Awareness and infrastructure for monitoring the regulatory requirements of the country where products are produced and/or marketed.
4. Product traceability, recall, and incident and crisis management.
5. Product development.
6. Raw materials and supplier management; this should also include any possibility of fraud or adulteration.
7. Good hygienic practice.
8. HACCP system and implementation.
9. Verification activities (consumer complaints, pathogen and environmental monitoring, review of noncompliances, and their root cause analysis).

The decision on the scope and frequency of audits will depend on a number of considerations, in particular whether the audit is a first audit or a follow-up audit. Whether a full or a partial audit is carried out will depend on the original purpose of the audit. For example, partial audits might be appropriate for closing out noncompliances, for investigatory purposes after an incident, or where a previous audit has confirmed that a sound system is in place.

Classification of risks is an important criterion for prioritizing and deciding on the frequency, i.e., having more frequent audits at higher-risk premises or suppliers of high-risk material. The following information can be considered in the classification of risks and in deciding on the frequency and scope of the audits:

1. the potential hazards known to be associated with the product and/ or process, including the previous records of safety of the product;
2. the history or level of previous compliance;
3. the state of the food safety management systems and other management systems that may be in place, for example, ISO quality management systems and certification, total quality management (TQM), as well as the level of in-house expertise; and
4. other considerations such as processing methods, intended use and population at risk, size of operation (e.g., number of employees, volume of production, and turnover), type of products and processes, complexity of operation, quantity of product affected by the raw material used, market, or trade requirements.

Similarly, the following could be considered in deciding the scope of an audit:

1. whether it is an initial audit or a follow-up;
2. size of operation, for example, number of employees, volume of production, and turnover;
3. type of products and processes;
4. complexity of operation;
5. level of in-house expertise;
6. amount of available resources;
7. presence of management systems, for example, ISO quality management systems, and TQM;
8. results of previous audits; and
9. population at risk.

A change in the system (process, formulation, etc.), or the aftermath of a natural accident or disaster, for example, fire, flood, etc., can also justify an audit. As mentioned previously, audits may also be triggered as results of a previous food safety incident.

Subsequent frequencies for audits and their scope can be considered in the light of such findings.

Competence of Auditors

The validity of audits depends to a great extent on the competencies of auditors and their integrity. Food safety being a multifaceted subject, a carefully selected team of experts will be required. The composition of this team and the expertise of the members will be all the more important as the

responsibility for protecting public health is significant. In any case, for a full scope audit, the following competences, skills, and qualifications need to be considered:

1. the technical competence,
2. the skills in assessing and investigating (audit skills),
3. the people skills, i.e., independence of judgment, integrity and objectivity, and finally, a good audit requires, and
4. the cooperation and openness of the audit entity in providing truthful information.

Other factors such as time and financial constraints, availability of documents, also play a significant role.

With regard to technical knowledge, the following are needed at the very least:

1. Understanding the basic hygienic requirements, their relevance in supporting safe food production, and experience in assessing them.
2. Knowledge of laws, regulations, standards and general codes of hygiene, and/or criteria for the specific category of products.
3. Knowledge of relevant industry products and processes (including past failures in the category).
4. Knowledge of the HACCP system and its application, including:
   a. The identification and audit of potential hazards which may occur during food production, handling, preparation, storage, and transportation, including biological, chemical, and physical hazards.
   b. The ability to assess the effectiveness of control measures (validation) of the HACCP plan and its verification.
5. Understanding the role of the human factor and of company culture in food safety.

Reporting Structure

Another important factor in the validity of the audits is the organizational structure and the management reporting system. To prevent conflicts of interest, and ensure that corporate governance is functioning in all independence, it is important that audits are carried out by teams of professionals who are structurally independent from those who are designing and implementing the food safety management system.

The Procedure and Methodology

The procedure for an audit must be defined and carried out in accordance with a set format. Auditors should ensure that they plan the process properly, i.e., that:

1. The scope of the audit is predetermined and sufficient time is allocated.
2. The required skills are available within the team.
3. Tools needed are made available.
4. Arrangements are communicated and agreed upon with the site being assessed.

The procedures for audit will need to include the following stages:

1. a planning process to prioritize establishments, operations and their frequency, and scope of audits;
2. a desktop audit;
3. an on-site audit;
4. an evaluation process to analyze findings, determine compliance, and decide corrective actions and follow-up requirements; and
5. reporting and follow-up.

The Planning Process

Initial planning is important to clarify the scope of the audit and the approach that will be taken on-site. It helps to ensure that auditors have the necessary information and tools to complete an effective audit. Information that will help in this planning process includes:

1. relevant company documentation;
2. previous file records, data on premises and products; and
3. results from previous visits or audits.

The Desktop Audit

The audit itself is best carried out in two steps. The first stage, desktop audit, consists of the initial review of documentation, which may be carried out on- or off-site.

A desktop review also has the advantage of enabling auditors to plan their work, for example, to judge how the CCPs have been established, check the personnel required for detailed discussions, the specific questions to be asked, draw a list of priorities to focus on, and/or areas to visit during the on-site audit.

Examples of documents to review:

1. The food safety policy.
2. The organigramme, the responsibilities of the managers and food safety management team, and their respective technical expertise and competences.
3. The operation, and the type of products produced.
4. The range and number of raw materials used and their origin.
5. A site layout plan may give an idea of the flow of products through the site, the scale of the operation and the products produced.
6. The HACCP-related documentation, including:
   a. a process flow diagram and specifications relating to it,
   b. the HACCP study (showing how potential hazards have been identified and on which basis they are considered as nonsignificant if this is the case),
   c. an HACCP plan, including the monitoring plan and the validation of the control measures,
   d. records of CCP monitoring and corrective actions following the violation, and
   e. verification data, for example, consumer complaints, monitoring data for raw material, environment or end products, and reports of incidents and root cause analyses.
7. Training programs, for example, the manual or other tools used for training.

8. Incident and crisis management procedures.
9. Reports of management review of food safety and quality.

On-Site Audit

The second stage is the on-site audit.

The on-site audit will normally start with an initial or opening meeting to confirm, with the key people being assessed, the audit scope, timetable, facilities, and personnel required and in general to ensure cooperation.

The purpose of this step of the audit is to confirm that procedures and practices described in the food safety management system of the company or the regulatory requirements to ensure food safety are properly implemented in practice.

During the on-site visit, specific attention should be given to HACCP and prerequisite programs, including:

1. Confirmation of the accuracy of the process flow diagram(s). This is facilitated by an initial walk through the site. The auditor will subsequently need to engage in a range of questioning and investigative activities to assess the efficacy of the HACCP system.
2. Evaluation of the hazard analysis based on the state of the prerequisite programs mentioned above.
3. Confirmation of the suitability of CCPs, critical limits, and corrective actions.
4. That monitoring schedules are established and operating correctly.
5. Confirmation that persons responsible at CCPs perform activities correctly, understand the importance of the step for safety, and their responsibility in case Critical Limits are violated. This will require specific interviews with the personnel.
6. Establishing whether effective verification procedures are carried out.
7. Reviewing monitoring data of raw materials, products, environment, CCPs, as well as reports of internal audits, supplier's audits (inclusive of supplier monitoring programs), consumer complaints, personal reports, and complaints. It is particularly important to corroborate these results with the hazard analysis (for instance, if a contaminant is considered as not significant in the raw material, this is confirmed through the monitoring carried out for verification).

During these activities, the auditors will need to keep sufficiently detailed records and to collect supporting evidence to enable conclusions to be made. Use of checklists together with a narrative, notebooks, or where appropriate, tape recorders, will assist this process. Depending on the judgment of the auditors, checks might be made on items of equipment, on-site measurements may be carried out, or product or environmental samples may be taken for subsequent laboratory analysis.

Evaluation Process

The auditor (or the team) will need to identify and analyze all information obtained during the audit in order to draw up preliminary conclusions of deficiencies found, if any, and their effect on food safety, regulatory compliance, or other trade-related concerns. They should also advise on their severity and the speed with which they would need to be rectified.

Reporting and Follow-Up

The format of auditor reports varies according to company policy and prior agreements with auditing bodies. However, it is essential that the results of the audit be communicated to the management of the company and to all relevant persons within the organization (i.e., with responsibility for safety) in a timely manner.

Where an audit report indicates critical or serious gaps, these need to be followed up rapidly, and root cause analyses of these gaps are also made to identify the latent cause of the failures.

Conclusion

Audit of food safety management systems is an opportunity to improve food safety management and close the gaps. They should be carried out with objectivity and integrity. An unsatisfactory audit report should not always and necessarily be a reason for reprimanding the managers; rather over and above closing the gaps, a root cause analysis of the situation should be made and short- or long-term corrective action should be made. Not infrequently, the root of the problem may be in the management.

Reports of audits and food incidents have shown that some of the major source of food safety problems are:

1. Raw material and supplier management.
2. Failure in the design of equipment and their maintenance.
3. Good hygienic practice violation.
4. Failure in hazard identification.
5. CCP monitoring failure.
6. Failure in corrective actions.
7. Human negligence or error.

Acknowledgment

The authors would like to acknowledge that this article is based on personal experiences, and is also inspired from an earlier work, i.e., the FAO/WHO Expert Consultation that she convened on the subject of the Role of Government Agencies in Assessing HACCP (Geneva, 2–6 June 1998). The report of this meeting is available from the link http://www.who.int/foodsafety/fs_management/en/haccp98.pdf under the title Guidance on Regulatory Assessment of HACCP. The contribution of all experts in providing the guidance during the consultation is thankfully acknowledged. In spite of the date of publication of the report, much of the guidance is still up-to-date and relevant.

FOOD SAFETY ASSURANCE SYSTEMS

Quality Assurance and Good Laboratory Practice

M Farrell-Evans, US Food and Drug Administration, College Park, MD, USA
W Warren, AEGIS Food Testing Laboratories, North Sioux City, SD, USA

Glossary

Accreditation The granting of approval to a laboratory by an official review board after it has met specific requirements.
Federal regulatory agency An agency that functions under the executive branch of the US federal government established to generate and enforce rules.
Good laboratory practice A system of management controls for laboratories and research organizations to ensure the quality, integrity, consistency, and reliability of results.
International Organization for Standardization (ISO) It is responsible for development of voluntary international standards for products, services, and practices.
Laboratory quality system A continuous process consisting of planning and documenting to control laboratory functions culminating in the generation of reliable data.
National Environmental Laboratory Accreditation Conference (NELAC) It is sponsored by the US Environmental Protection Agency and accredited under the NELAP. Established performance standards for environmental laboratories, to produce environmental laboratory data of reliable, documented quality.
Quality assurance A system for evaluating adherence to, and performance of, quality control (QC) in a laboratory, for the purpose of ensuring demonstration of competence and generation of defensible, reliable data.
Quality control Laboratory QC is performance of standard operating procedures (SOPs) and control activities to ensure standardized analysis. The control activities are designed to detect, reduce, and correct deficiencies in a laboratory's internal analytical process before the release of results.
Reliable data Data derived from laboratory results that are valid and credible.
Scope Testing areas (procedures, assays, and SOPs) that have been evaluated and conformed to standards as established by the accreditation body.
Standardization The process of developing standards that are universally applied to ensure consensus and compatibility.
Validation Practice undertaken to substantiate or confirm methods or procedures perform as expected and in a reliable manner and consistently meet expectations.

Introduction to Quality

Elements of a Quality System and Generation of Reliable Data

The term 'quality' has relative meaning in general conversation, but in a laboratory setting quality is specific, as in a plan employed to ensure production of legally defensible, reliable data that can be used to support well-informed decisions. For many food testing laboratories this plan, often referred to as a quality assurance (QA) plan, compiles specific and prescribed series of documents that collectively support accurate and defensible results. Defensibility of results demands laboratory competency, which is founded on verified compliance with documented procedures and proven proficiency, and thus, ability to generate valid and credible data.

So how does a laboratory ensure generation of reliable data? Competent laboratories often voluntarily obtain accreditation from a recognized, third party accreditation body that verifies procedural compliance and technical competency. There are myriad written standards for quality system evaluations depending on the type of lab; however, a common standard of evaluating laboratory competence is the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC). ISO develops and publishes international standards for many sectors that are derived by experts in their fields. There are also standards for accreditation developed for specific commodities directly by processors and/or those providing oversight and governance. Often, measurably verified standards are mandated for laboratories generating data that are deemed reliable and defensible for specific commodities.

Quality Accreditation Types and Jurisdictions

Independent accrediting bodies are utilized to lend credence to data generated by both foreign and domestic accredited laboratories. The accreditation a laboratory holds often acts as an assurance that a minimum standard has been achieved and will be maintained. Though it is no guarantee, independent accreditation assures that a quality system exists and the

analysis the lab includes on its scope of accredited test methods has been validated. Part of the accreditation process includes an independent examination of the laboratory scope, which includes what type of analysis was performed, what type of matrix the lab analyzed, the target of the analysis, and the technique used for analysis, including the range or limit of detection or quantitation. Laboratories may also perform analysis not listed on their scope; however, the accreditation imparted on the lab will not cover the analysis. Many private laboratories, either research or third party contract testing labs, will have a 'special projects' or research division, which will not maintain the same level of standardization. They should, however, maintain the same level of QA and quality control (QC), in the form of compliance verification.

Laboratory accreditation is directly related to the type of testing it performs. There are accrediting bodies for clinical, calibration, environmental, and food laboratories. For example, a laboratory that performs drinking water analysis might obtain a National Environmental Laboratory Accreditation Conference Drinking Water Lab Certification. A food testing laboratory might acquire an ISO/IEC17025:2005 accreditation. This provides general requirements for the competence of testing and calibration laboratories, and is universally recognized. The standard is used by laboratories developing a system of QA. The US Food and Drug Administration's (FDA) recent passage of the Food Safety Modernization Act (FSMA) required laboratories testing FDA-regulated food commodities, under section 202 – Laboratory Accreditation, to be accredited. As a result, many labs maintain QC/QA programs that adhere to ISO quality guidelines and standards. FSMA was developed to ensure the US food supply and public health were protected by shifting the focus to prevention and strengthening regulatory authority.

Similarly, the US Department of Agriculture Food Safety and Inspection Service (USDA-FSIS) recently issued a policy guidance document entitled, "Establishment Guidance for the Selection of a Commercial or Private Microbiological Testing Laboratory" to provide criteria to meat, poultry, and processed egg processors for selecting laboratories to analyze establishment samples. The purpose of this document is to clarify key considerations and responsibilities of the establishment in verifying the QA/QC practices of their laboratory provider. Issuance of this guidance and communication of responsibilities places a greater level of emphasis on the importance of verified laboratory QA/QC practices as part of the overall food manufacturing process and detection of foodborne pathogens. Such activities will continue to increase awareness, improve transparency, and increase stringency of monitoring laboratory compliance. Overall, such activities support a better avenue for detection of potential food safety hazards in a preventative manner.

Oversight of Accreditation

Part of the strategy for prevention of chemical, physical, and biological food safety hazards is detection of the hazardous food product before its entry into commerce. A laboratory must be capable of generating reliable data if public health decisions will be determined based on results. Though not a guarantee, an accreditation acts as a formal acknowledgment for customers to consider when they identify and select a reliable testing laboratory. It assures a quality system is in place, which is a necessary component in any competent laboratory; however, a quality system without daily implementation serves no purpose. The laboratory quality system is only as good as the staff adherence and support it garners. The elements of a comprehensive quality system must be more than a paperwork exercise. Laboratories with strong quality programs have several drivers including bench-level analysts with an inherent aptitude and commitment to the laboratory quality system, the commitment of time and resources from management for implementation, and recognition and value placed on successful QC. If the commitment to quality is as powerful a motivator as profit margins and return on investments it will be valued by all laboratory staff, and rewarded by management. This will ensure that effective implementation will not require constant policing. It will be evident to the auditor, by the lack of careless errors such as data obliterations or inadequate daily record keeping and poor organization. For the laboratory quality system to be truly effective, it must be adopted into the culture of the laboratory from management to analyst level, and palpable by the external auditors and customers of the lab.

Development and implementation of a comprehensive laboratory quality system, required for defending technical competence of laboratories, will be founded on good laboratory practices (GLPs), quality management (QM), QA, and QC. These often exist in most regulatory or contract testing laboratories but are not usually points of focus in research laboratories. Clinical laboratories have undergone a similar transition in an effort to bridge the quality gap between applied and theoretical research, and food laboratories are no different. The development and implementation phase of laboratory quality is time consuming, expensive and often requires external consultation. In the end, data are only as reliable as the lab in which they were generated. Research methods may indeed become validated methods utilized in food laboratories, thus quality systems should exist as the methods are being developed. Adherence by a laboratory to a quality system is a step toward the goal of generation of reliable data. Having a culture of quality in the lab is a means to that end.

Evolution of the Quality Concept

The culture of quality has evolved over many years and will continue to progress to meet the needs of analyses as they advance, and of analysts as they continue to increase in technical proficiency. When the level of sophistication increases, the quality system of a laboratory must address possible deviations and necessities of standardization. Even under the best of circumstances, variations will exist, between reagents and supplies and even between analysts. A quality system must aim to minimize these events and account for an uncertainty in reported results. To determine the future of quality systems and how they must adapt, an overview of past principles is beneficial. As with many scientific disciplines, the field of quality evolves and builds on past successes.

To continue to maintain a quality system that meets the needs of a laboratory, quality managers and staff must understand the foundation from which the quality system is created.

The Past: GLP

Only as Good as the Oversight

For nonclinical laboratories, in this case food testing laboratories, the Code of Federal Regulations Title 21 Part 58 (21 CFR 58) is the regulation that dictates guidance for quality. This was drafted specifically for all laboratories not involved in performing clinical studies or field trials with animals or humans. GLP was proposed and first adopted by FDA, then Environmental Protection Agency (EPA) in response to an incident of research and development fraud in the late 1970s. In 1981, the Organization for Economic Cooperation and Development also published GLP principles, prompting international adoption. As a result of the adopted legislation, laboratories are allowed flexibility in conducting nonclinical studies while still guaranteeing a quality program is in place with an inspection component to maintain existing systems. The desired outcome of the regulation was to protect public health and ensure satisfactory laboratory compliance during agency inspections. GLP is often equated with technical skill. This is not the case. Technical skill and technique are obviously important facets of generating reliable data, but they are not the whole story. Consistent production of reliable data requires another level of diligent evaluation, even if GLPs are in place. Although some guidance is provided in determining qualifications of key personnel based on education and training, determination of the ability of a laboratory staff to conduct a procedure with technical accuracy can rely heavily on third party audits and specifically on the experience level of the auditor.

GLPs: Introduction to Standardization and Transparency

GLP is an overarching set of practices that play a part in all aspects of laboratory function. GLP is far more than standard operating procedures (SOPs). GLPs may be considered a 'what if' plan of action. What happens if equipment fails? What are the criteria for samples to be accepted in the laboratory? Is there a rejection criterion? How can the laboratory prove the analysis was accurate and minimize analyst error? The time to figure out how to proceed is not in the middle of the laboratory anomalous event. GLPs are in place to ensure sample integrity and method validity. They are standards that keep the lab running and ensure an event will be handled in a way that is defensible, standardized, and controlled. Having established GLPs in a food testing laboratory ensures an analyst will know what to do when the unforeseen inevitably presents itself, in the areas of lab function, safety and health, data handling, as well as in the routine aspects of the lab function.

GLP Highlights

21 CFR 58 addresses routine maintenance and calibration, sample traceability records, and development and implementation of quality systems. According to the World Health Organization, all GLP texts, irrespective of their origin, stress the importance of the following fundamental areas:

1. *Resources*: Organization, personnel, facilities, and equipment. A clear understanding of resources will allow laboratories to contract and perform analysis while adhering to quality framework.
2. *Characterization*: Test items and test systems. Validation of laboratory testing options and troubleshooting food matrices is a challenging endeavor and integral to successful data generation. Which analyses can a laboratory reliably perform?
3. *Rules*: Study plans (or protocols) and written procedures. These documents are part of QC in any laboratory and should be controlled. 'Tweaks' are not permitted! Changes increase variability and method uncertainty.
4. *Results*: Raw data, final report, and archives. Data are only as reliable as the laboratory from which they were generated.
5. *QA*: ISO 4.1.5 (a) is specific in ISO/IEC17025, that a laboratory shall have personnel with the authority and resources needed to implement, maintain, and improve the QM system (QMS), and to identify the occurrence of departures. They also should have the ability to initiate actions to prevent or minimize such departures from the established system QC.

Guidance for Laboratory Quality and Its Evolution

The modern concept of QM and QA is directly related to GLP; however, modern interpretation tends to be more prescriptive. The quality manual can be traced to GLPs, which require laboratory manuals and SOPs. As laboratory functions are so varied, there is no standard format for a quality manual across laboratories, although accrediting bodies will often provide a guide. The QM aspect of the overall laboratory quality system in a lab is typically GLP-based and includes a specific set of goals. The guidebook for the laboratory quality system is the quality manual, which should make clear the goals and requirements of how the quality system is managed. It should describe in details, the policies and procedures the laboratory has in place to assure the quality system is functioning as intended.

Only as Good as the Analyst

QA and QC support the management structure and theoretically ensure that the laboratory produces defensible, reliable data. However, the execution of the established system is what ultimately determines reliability of the data. The analysts carrying out each step of the quality plan are a variable, and clearly not all variables can be controlled. This has less to do with analyst skill and more to do with the prescriptive and standardized practice of laboratory quality. Blatant disregard for GLP guidance or laboratory accidents can be discovered and dealt with; however, variation based on human error or interpretation may be the root cause of laboratory issues. Although GLPs were an excellent start to managing quality in nonclinical laboratories, the dynamic nature of food analysis

has demanded that more be done to minimize variations in analysis and results.

The Present: QM, QA, and QC

QM

The next iteration of GLP is the QMS. Though directly related to GLPs a QMS is very specific. QMS is the system in place to ensure the laboratory not only develops but also adheres to guidance in the form of quality manual, quality procedures, technical procedures, administrative procedures, work instructions, and requirements for record keeping. A QMS is only as effective as the QA and QC within each laboratory (Figure 1). Collectively, each component is essential to the production of reliable data.

Most laboratories display a unique quality statement that essentially imparts the same message: The quality system in this laboratory assures the data are reliable. But is that really the case? QM, though similar in scope to GLP, is specific and all encompassing. Documentation is the key to any quality system. The 'golden rule' of quality is this: If it is not written down, it did not happen! The QMS must be adopted from the top down and must be practiced by all. The QMS is the encompassing system by which the lab functions, but it is supported by the following Sections QA: The Rule Book for Reliable Data and QC.

The quality system sets the tone for everything that happens in the laboratory. If there is no acceptance from laboratory management to the analyst level, the efficacy of the laboratory's quality system may be in question. This is where the concept of transparency becomes critical. The transparency of laboratory quality systems and the procedures in place to support the system are key to successful implementation.

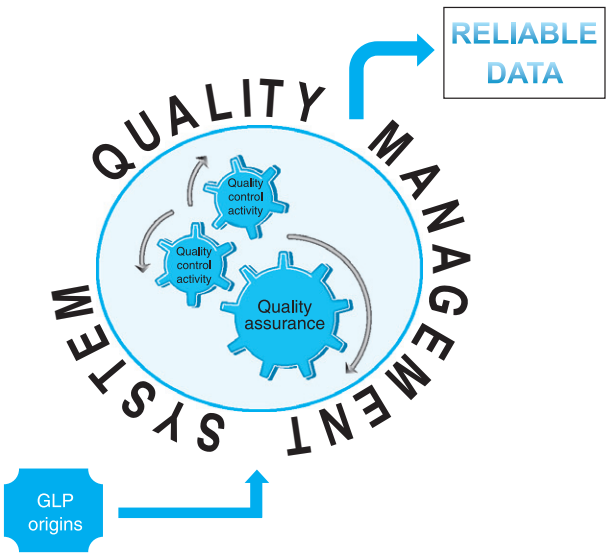

Figure 1 Quality structure in the laboratory. The QMS is only as strong as the supporting concepts of assurance and control. All the cogs must function to produce reliable data.

Performance assessments, both internal and external, are invaluable for laboratories to monitor the success or failure of their quality systems. The structure for monitoring should be clearly explained in the QA plan in any laboratory generating data.

QA: The Rule Book for Reliable Data

The term QA is exactly what the name implies: procedures in place to assure that the data generated by a laboratory are reliable. QA plans should contain explicit requirements to produce reliable data. These will include specific requirements for documentation of organization of the laboratory, staff training requirements, standard operating procedures (SOPs), QC measures for equipments, reagents, calibration, maintenance, repair and performance, laboratory safety, and testing methodology. The organizational chart of the lab may seem to be an insignificant aspect of the QA; however, chain of command is critical. Customers must know to whom they can address questions or complaints. Analysts encountering any errors or issues must know who to call and who has the authority to make an executive decision. Staff training requirements are an area that is often glossed over and satisfied by a checklist, which does not adequately address training. The purpose of staff training is to develop a metric to defend analyst competence. Without the ability to demonstrate analysts are proficient in performance of an assay, any unexpected results may be called into question as lab error.

QA is not just SOPs, though it is often the part labs spend the most time preparing. SOPs define how to carry out protocol-specified activities. Most often they are written in a chronological listing of action steps. Labs should have SOPs for all activities relating to quality and analysis. These should be controlled documents to ensure standardized practices throughout the lab. Multiple copies or a lack of document control leaves a lab open to method changes and nuances that are not applied universally. Often two other aspects of the QA plan, internal and external performance assessments, are under emphasized. External performance assessments are fairly straightforward; most laboratories participate in proficiency and/or split sample testing in one form or another. Internal performance assessments tend to be slightly more subjective. ISO requires that the laboratory shall periodically conduct internal audits of its activities to verify compliance with the management system and the ISO standard. This is a powerful tool that many laboratories fail to utilize. Nonconformities and errors cannot be found unless there is consistent review and auditing. This should be considered a process of continuous monitoring for the laboratory and a critical part of any quality system.

Putting the Assurance in QA

QA is the policy and paperwork aspect of the QMS. If followed it will, in theory, allow the lab to demonstrate competence and generate defensible reliable data. To ensure the quality system is intact, a third party should be available to check results and QA paperwork. This is another example of a process in place to assure the quality system is in place and

followed. Depending on the size of the laboratory this is not always possible. In this case, someone who is capable of affecting change and someone who has not performed the work should be chosen to review paperwork and results. QA is not one size fits all and often dependent on the types of products and analysis performed. Thus, critical review of program details on a case-by-case basis may be needed to ensure results are defensible and valid.

An appropriate analogy for a laboratory QA is a bonsai tree (yes, a bonsai tree)! A bonsai requires constant cultivation techniques like pruning, root reduction, defoliation, and grafting to produce the characteristic small trees. If the bonsai is ignored, you end up with a planter full of sticks, or a full-size tree. If the laboratory QA is ignored, a breakdown in quality systems will occur. This will ultimately lead to data that are neither reliable nor defensible. This, like a dead tree, is not the desired outcome!

QC

QC, the other side of the QMS, is primarily aimed at the documentation of specific actions performed to ensure quality and the prevention of errors that could affect the analysis or results a laboratory provides. Where QA is an implementation process that may be very similar in labs that perform similar functions, QC is very specific to the laboratory. Documentation and procedures may vary, however, QC should act as a safety net to ensure the QMS is in place and reliable data are generated. Yet, analysts are human and inevitably errors occur; however, if a lab has functional QC, errors will be detected and allow an avenue for process improvement.

Root Cause Analysis: Laboratory Detective

As with any good investigation, the lab will try to discover the root cause for an error. This will involve an investigation, or root cause analysis, into what happened, how and where did the error occur, why did it happen, and who was involved? Once these questions are answered, corrective action can be taken and steps can be implemented to prevent the same mistake from being repeated. Sometimes finding the root cause itself can be a challenge, which is usually reflected by repeated issues of the same type. The investigation for the correct root cause will continue until the appropriate corrective action can be taken. An important element of this process is the cooperation of all staff. If this process is conducted in an accusatory manner, it may not provide the desired results. If this process is conducted with a spirit of continuous improvement overall quality system, the lab can work in cooperation to improve. If the lab understands the error may have occurred at the hand of one or a few, but the ultimate responsibility lies with the plan, the individual blame and associated morale issues may be mitigated.

Documentation: The Key to Quality

QC, as with all aspects of the laboratory quality system, hinges on adequate documentation. Documentation in the form of written logs or documentation via a laboratory information management system must be in use and able to be retrieved. To achieve traceability of managed or controlled documents, QC logs for media preparation should be maintained and must include several pieces of information, including date made, name of media, lot number, expiration date, amount of media weighed, and volume prepared. Several areas are integral for proper QC. The first is maintaining proper chain of custody throughout the evaluation process. Once samples are obtained, a laboratory code for identification must be assigned. It is a critical step that ensures the results from the analysis of a sample actually are from that sample. The identification number should follow the sample throughout its time in the laboratory from the front door to the release of the result. Another area of critical QC is purchasing, receiving, and storing consumable materials (i.e., disposables, media, and reagents). The laboratory should maintain a QC log that includes item name, manufacturer, lot number, amount, date received, and expiration date. The person receiving or opening the consumable must also initial the physical container. This ensures materials used in analysis are in date and any error may not be attributed to reagents, consumables, or any materials used in the analysis.

Calibrations

It is also expected that a food testing laboratory will have written documentation of calibrations and verifications for reagent preparation, which must be accessible for laboratory evaluation. There are also several areas of QC that will have a critical impact on analysis and defensibility. These general areas of documentation are water quality, media and reagent sterilization, calibration (thermometer, balances, pH meter, etc.), productivity and process controls, and all quality-dependent actions as listed in the quality manual. The concept of calibration of staff via training and proficiency may sound abstract; however, staff training and monitoring are designed to achieve just that. Each analyst shall perform the same method the same way, culminating in the same result, at least in theory. Most of these activities are fairly intuitive for the seasoned analyst; however, controls are often a source of consternation and debate regardless of the assay.

Analytical QC samples and control charts are another tool in the QC toolbox that have a critical impact on analysis and defensibility. This method of statistical control, traceable to the analyst level, is often common practice in both chemical and microbiological food analysis laboratories. It is a continual check of analyst precision and critical component of many laboratory accreditation programs. Precision is often utilized to determine measurement uncertainty (MU). Though there are courses and manuscripts devoted to this principle alone, briefly, the estimation of uncertainty based on reproducibility estimates and control charting is often implemented in laboratories as opposed to complex statistical calculations. Use of suitable control samples or secondary reference materials to measure reproducibility and repeatability allow laboratories to determine MU, which accredited laboratories, under ISO/IEC17025 (section 5.4.6.3), are required to determine and make available to clients and auditors when requested.

Controls for Productivity of Media and the Process

Including positive and negative controls with samples for analysis is a common practice and an established example of GLP. When interpreting sample results, the analyst or supervisor uses control results to confirm the validity of positive or negative findings. For example, in microbiological analysis, a positive control confirms that the target bacteria the media supports were able to grow; bacteria that were not desired to grow were in fact inhibited and that the uninoculated media, buffers, or water used during the analysis were sterile. These control results support the assumptions that any bacteria found must have originated from the inoculated environmental sample or any lack of bacteria found was not due to sampling or lab error.

Productivity controls serve to verify the media is capable of performing its function. For example, does a Gram-negative media support growth of a Gram-negative organism? If the answer is yes, the media is productive. The inverse of this is also important to verify. Will organisms that are expected to be inhibited fail to grow? Productivity controls determine if the media is made correctly and if it is suitable for use. It is optimal for media productivity to be confirmed before release for use by analysts.

Process controls determine if specific environmental conditions exist at the appropriate intervals to support growth of the target organism(s) while inhibiting competing or background flora. These controls are prepared at the time of testing and ideally should represent the levels expected in the sample for analysis. Continuing to use the example of microbiological analysis, if an analysis target is detection of <100 colony forming units (CFU), controls of 10 000 CFU may not be adequate to ensure a sample containing fewer organisms had the necessary components for growth and proliferation. The intent of a positive control is to produce a positive response when actual conditions or levels of samples are replicated.

Particularly in a laboratory with a chemistry focus, certified reference materials are an integral part of laboratory QA/QC. The use of certified or standardized reference materials (both in solution and matrix) is important in establishing accuracy in chemical analysis, internally validating a method for the laboratory, and provide a tool to determine traceability and MU. Organizations such as the National Institute of Standards and Technology and the National Research Council, Canada provide standard reference materials, standard reference data, and sometimes proficiency evaluation materials, so labs can determine the efficacy of their QA programs and assist a customer in establishing traceability of measurement results. This is a critical component of any quality system, continual commitment to the culture of quality and data defensibility.

QC is typically the element of laboratory quality analysts are most familiar with, and often times these actions are performed by rote. An understanding of the importance of each control and what it is aimed at preventing is a significant step in minimizing errors and creating a culture of quality in the food testing laboratory.

Future

The future of laboratory quality is greater transparency, oversight, and standardization. Third party audits have become an accepted and common occurrence by the food industry in an effort to improve food safety, and the laboratory is no exception. An independent laboratory must trust that the sample provided by the customer was gathered properly. Other than offering guidance and rejection criteria, there is little that the lab can control before sample receipt. There are two elements that laboratories have entirely within their control that impact the reliability of their data that have in the past been left up to the individual laboratory to oversee.

1. How the sample is prepared: Has the laboratory optimized preparation for efficient delivery of the target for detection?
2. How testing was conducted: Were the methods fit for purpose and performed appropriately?

The concept of 'fit for purpose' validation is important in terms of making sure a test method is applied according to the manner in which it was validated. In the past Association of Official Analytical Chemists (AOAC, now AOAC International) would validate a method based on Official Methods of Analysis and a method was used. This process has undergone standardization and is now streamlined in what is known as Standard Methods Performance Requirements. This process was extensive and involved a multiple laboratory validation protocol. The FDA's Bacteriological Analytical Manual and FSIS's Microbiology Laboratory Guidebook both list validated microbiological methods for food matrix analysis, including sample preparation, isolation, and identification of the major foodborne pathogenic microorganisms and their toxins. Recently method validations have become more varied, and many commodity producers have self-governed the validation process in which new detection methods are determined to be fit for purpose. For this reason, technical evaluations have become an even more crucial part of a program evaluation or audit.

Audit Changes and Auditor Qualifications

The changes in validation and selection of methods may necessitate a shift in how audits are conducted. In the future, reviewing protocol and practice along with a critical review of key areas that could affect outcome of the test may be crucial to ensuring reliable data. A focus on technical audits will highlight the importance of the auditor and his/her qualifications. The evaluator may be required to not only observe the method as performed per the SOP but also s/he may be called upon to make determinations about method selection and analytical proficiency. The level of sophistication of analysis and the commitment to QA may also require the training needs of bench-level technician to increase. Both auditor and technician will have to understand not only how to perform the method but also the reasoning behind the SOP.

The Global Food Supply and Changes to Quality Systems

As we move toward a more global food supply, greater importance is placed on accreditation program standardization and method validation. When there is a worldwide call for an

ISO or ISO equivalent auditing system, two questions come to mind.

1. Even with increased transparency in lab methodology and auditing procedures, how do we guarantee international harmonization for our food/raw materials that are imported?
2. Who decides what is ISO equivalent?

The truth is, at this point, the answer is not clear cut. FSMA has stressed the importance of harmonization for testing, especially for imports. However in 2000, the Global Food Safety Initiative (GFSI) was launched at the retail level on an international scope. GFSI has recognized several schemes, based on the food safety standards of the Codex Alimentarius for the purpose of common requirements universally implemented in audits of food establishments. This is a global endeavor, but of the accepted programs, British Retail Consortium (BRC) and Safe Quality Food (SQF) have been widely adopted in the US. The concept of food product testing being a component of the manufacturing process is one that has been embraced by several large retailers. As SQF explains, one link in the food chain does not get rattled without it affecting the next link. The need for standardization is ever increasing; it is imperative to utilize properly validated systems that employ continuous monitoring.

Balancing Act

The widespread acceptance of BRC and SQF is just one example of industry changes affecting laboratory testing. There is also a concerted effort to take successful manufacturing principles and implement the ideals in the laboratory. It is naïve to think that a laboratory is not a business, clearly it is and pressures to drive profits can lead to compromised quality systems. There will inevitably be laboratories that make profit-driven decisions, potentially compromising the quality system. The concept and practice of continuous quality system monitoring may identify areas of system weakness. This benefits the industry as a whole, both the testing laboratory and the industry contracting the analysis for their product.

So How Does This Affect Laboratory Quality?

Changes at the retail level affect the laboratory. In Edition 7 of the SQF Code, dated 1 July 2012, it states: "Where external laboratories are utilized to conduct input or product analysis, the laboratories shall be accredited to ISO 17025 or an equivalent national standard."

As an 'equivalent national standard' is unclear at best, the quality system in laboratories of the future must be founded on core quality principles but flexible enough to adapt to changing demands. The QA must be living documents, capable of rising to the challenge of changing technology, tighter budgets, and transparent global standards. The evolution of GLP and QA will continue to grow and change to meet the needs of an ever changing global food supply. These changes have required both regulatory bodies and private industries to strive for a standardized and prescriptive metric, with greater transparency and oversight. As we move down a path toward a culture of quality and reliable data production, our food supply will be safer and public health will be protected.

Investigation of Incidents in Industry

P McClure, Unilever R&D, Sharnbrook, Bedfordshire, UK

Glossary

'At risk' period The period of time during which a batch or batches of food are suspected of being affected by a failure in manufacturing.
Consumer complaint system A system that records information related to consumers complaints.
Crisis An incident that is out of control.
Direct cause The cause that directly resulted in the incident occurring, e.g. failure of a sterilization process due to faulty steam supply.
Disease surveillance The monitoring of foodborne disease cases to establish patterns of progression of disease.
Hazard A biological, chemical or physical agent in, or condition of, food with the potential to cause an adverse health effect.
Incident A 'loss of control' situation, where a company accidentally produced or distributed product that may endanger consumer's health or the Brand's or company's reputation.
Incident investigation The investigation of an incident to identify the direct and underlying causes with the purpose of identifying corrective actions to prevent recurrence.
Risk A function of the probability of an adverse health effect and the severity of that effect, consequential to a hazard(s) in food.
Underlying cause The basic cause that if corrected, would prevent the incident occurring, e.g. underlying cause of steam failure in sterilization may be due to inadequate equipment maintenance linked to poor training of personnel.

Introduction

Foodborne disease continues to be a major concern for public health worldwide. Food businesses are responsible for the safety of food that they manufacture, source, pack, transport, or market, and it is a fundamental principle that those businesses must not place unsafe food on the market. Nevertheless, incidents involving food manufacturers continue to contribute to foodborne disease to varying degrees, with some of these involving large volumes of food, affecting large numbers of exposed consumers. The continuing occurrence of these incidents is disconcerting given the efforts made to improve food safety over the past 40 years or so, where this period has seen the introduction of food safety standards, practices, procedures, and food safety management systems, such as the hazard analysis and critical control point (HACCP) system that are designed to reduce the likelihood of these events occurring. Moreover, many of the incidents are recurring events caused by the same or similar failures where it would be expected that lessons would already have been learned. These failures are often associated with poor implementation of 'prerequisites' such as cleaning and disinfection, and good manufacturing practices and poor hazard analysis or in general implementation of the HACCP system.

The predominant cause of incidents in many regions continues to be presence of biologic hazards with the majority of these incidents being caused by microbial agents. This article focuses on the principles to be used in the investigation of incidents with the primary purpose of identifying underlying causes that, if addressed appropriately, should prevent recurrence. It does not provide detail of the different methods that should be used for analysis of different pathogens/toxins as these are being developed on a continuing basis and they are too numerous to cover here.

The other potential causes of incidents include presence of allergens, chemical contaminants, naturally occurring toxins, foreign bodies, or other physical hazards such as glass or metals, incorrect labeling, and other regulatory noncompliance issues. These are not considered in this article, although many of the principles described below will be relevant for these other causes. For further information on this aspect, the reader is referred to Motarjemi and Wallace (2013).

Impact of Incidents

The impact of these incidents can be significant, both from a public health perspective and also from an economic point of view, and a number of these are identified in Table 1. The scale of these various costs varies according to the nature of the incident, the amount of product affected, the amount of product released to the market, the reaction to the incident from consumers, retailers, and the media. In recent years, due to large scale manufacturing and distribution of products, there have been a number of incidents affecting large numbers of individuals spread over wide geographic regions. In some

Table 1 Company costs associated with incidents

Internal costs	*External costs*
Scrap/waste and safe disposal	Loss of sales
Reworking of product	Complaint adjustment
Retesting of product and manufacturing environment	Recovery/return of affected product
Failure analysis	Warranty charges
Downtime in manufacturing	Liability costs
Yield losses	Loss of contracts/shelf space
Reconfigure/redesign	Loss of reputation
Recommissioning	Loss of brands
Verification	Loss of market share
	Loss of business

cases, the damage caused by the incident has resulted in prosecution and in extreme cases, bankruptcy for the business affected, and there is often a knock-on effect for businesses marketing similar products. For example, an outbreak of *Escherichia coli* O157:H7-related foodborne disease attributed to contaminated spinach in the US in 2006 resulted in losses of US$12 million worth of farm sales of spinach and a retail loss of over US$63 million. In outbreaks where the vehicle responsible has not been properly identified, losses can be equally serious for foods that may only be suspected, erroneously, as a cause. For an outbreak of salmonellosis initially linked to fresh tomatoes in the US in 2008, tomato prices decreased and the farm-level loss was estimated to be US$25 million and retail loss was US$89 million. It was not until later that jalapeño peppers were identified as the true source of the outbreak. The figures estimated for public health costs will depend on the severity of illness caused and the health care required for the individuals affected. On average, estimated costs in the US are approximately US$1000 per case of illness. Some microorganisms cause serious life-threatening disease, whereas others may cause self-limiting illness that may only last for a short period. In some cases, incidents are caused by microorganisms that do not cause illness or disease but will cause deterioration in product quality and these can also have a significant impact, particularly on brand image and reputation.

The Incident Process

The first step in the incident process is receipt of information alerting the company or an external body (e.g., public health agency) that substandard product has been released to the market. These indications or signals can vary in nature and reach the company affected through different routes, from internal sources (e.g., quality records) or external sources, and it is important that companies have effective ways of capturing this information and that they have systems in place to react quickly.

The routes include:

- Consumer complaints – logged, trend analysis, assessment of changes;
- Information from sales force – sales representatives collect samples in case of suspected product defects;
- Complaints from the trade or other professional customers;
- Information about other manufacturer's problems – this requires an assessment of relevant overlap/structural similarity in the supply chain;
- Media – media monitoring and a triggering system for relevant products, brands, issues, and special consumer groups;
- Internal quality records;
- Trend analysis and reporting of noncompliances within the company, for example, using an internal system where manufacturing operations report noncompliances to those responsible for quality and safety; and
- Notification by authorities and rapid alert systems – early warning may depend on establishing and maintaining good working relationships and proper internal communication.

Preparedness Plans

It is critical that food businesses have systems in place that monitor for the signals associated with incidents and trigger initiation of the incident management and investigation processes, which should be regarded as two separate, but interdependent activities. The key components of incident management or preparedness plans include

- An assessment of vulnerability to incidents;
- Details of roles and responsibilities of personnel who will be involved in the response to the incident;
- Documented incident investigation and management procedures, including product withdrawal/recall procedures;
- Effective surveillance systems that are closely monitored and raise alerts as soon as out-of-normal patterns are evident;
- Traceability system for suppliers and customers;
- Capacity and capability (internal or external) to verify and investigate incidents; and
- Links to relevant regulatory and public health agencies and other bodies that are involved in the management of incidents.

An incident management team should include senior managers with a detailed knowledge of various functions within the food business, including safety/quality, sales, marketing/public relations, buying, production, distribution/logistics, regulatory affairs/legal, and consumer services. If in-house expertise is not available, it is essential that external bodies/organizations are identified that have the relevant skills, experience, and competencies necessary.

Supporting Systems

Two important aspects of incident investigation are rapid access to information/data and recording actions taken. These require supporting systems that are ideally integrated using computer systems and networks allowing easy and rapid access. The type of information that is often required in the early stages includes traceability records, stock inventory, process and quality assurance (QA) and quality control (QC) records.

It is essential that all the necessary information is available to allow detailed interrogation of these data. If such systems are not in place, the same information should be made available through alternative means, such as paper records.

Indicators of Incidents

Consumer Complaints

Collection, monitoring, and analysis of consumer complaints is an important activity for identifying problems associated with products. Consumer complaints are one of the primary sources of information indicating that an incident may be taking (or has taken) place. With microbiological hazards, the obvious signs of microbiological contamination may be noticed by consumers before or upon opening the affected packs. These signs include visible damage to the pack itself, presence of off-odors, and gas production (e.g., swelling of packs or containers), deterioration in product structure, visible growth of microorganisms (e.g., molds) on the food surface, and presence of off-flavors/tastes. In some cases, there may be no visible sign or noticeable sign of contamination, and in the case of some ready-to-eat foods, these may be consumed directly from the container where the visual cues are not perceptible before consumption. Contamination with pathogenic microorganisms, if present at sufficient levels, can often result in acute illness, either as a result of infection, toxicoinfection, or intoxication. In the case of intoxication, toxins from commonly reported pathogens such as *Staphylococcus aureus* and *Bacillus cereus* strains producing emetic toxin will cause illness in a matter of hours, whereas for infectious agents, the time to onset of symptoms may be matter of a few days to many weeks. All of this information is important for the investigation of the incident, particularly for aiding in the identification of the microorganism(s) associated with the incident. It is therefore essential that there is an effective consumer complaints system in place to capture and record this type of information.

Consumer Complaint System

The consumer complaint system should incorporate a number of features that include:

- Ability to search across different fields, such as name of complainant, nature of complaint, geographic region, time/date of the complaint, action taken in response to the complaint, and the product(s) and code, if available, associated with the complaint;
- A monitoring process that allows trending of data and assessment in a timely manner;
- An alert system to rapidly identify out-of-norm situations, for example, multiple complaints, including those of a different nature, from one food type;
- Integration with consumer complaint systems in other regions where affected products may have been distributed.

Poorly worded questionnaires or untrained personnel recording information may lead to problems going unrecognized or being misdiagnosed. The staff who are involved in consumer complaint systems, such as customer care lines, should be trained such that they are able to gather all the relevant information and are able to ensure they have the relevant contact details in case it is necessary to gather more details at a later date.

Consumer Complaint Data

To ensure that the information gathering process is effective, it is advisable to use a template that can be used by the complaint handler, prompting for the relevant information. The type of information collected is as follows:

- Contact details of the complainant;
- Nature of the complaint, including visible/sensory signs of contamination or pack damage and if any illness occurred;
- If illness occurred, the predominant symptoms and when these occurred (time and date), number of people ill, their symptoms, and others who may have been exposed;
- Details of physician or other medical personnel, if consulted and details of tests and test results, if carried out;
- Details of suspected food product consumed, including pack date code, reasons why particular food is suspected, unusual signs upon opening the pack, how the food was prepared and handled before consumption, unusual taste/flavor and how much food was consumed by each person exposed;
- Whereabouts of remaining product/container and same products purchased at the same time as the implicated product;
- Details of other foods consumed within the previous 72 h.

Complaints from the Trade or Other Professional Customers

Occasionally, defects in packs or packaging are detected during distribution, for example, when products are repacked into secondary packaging or when packs are stored in retail, on the shelf. Pack defects can include swollen or 'blowing' packs or blown packs, where the pressure of gas formation leads to the packs releasing their contents. Where pin holes are the cause of microbiological contamination postprocess, these are often difficult to detect.

Information about Other Manufacturers' Problems

It is important to monitor incidents that may be occurring with similar products on the market or with products that may be using common raw materials/ingredients. Trade associations and regulatory agencies can provide valuable information in this respect, where commonly used materials are identified and then companies potentially sourcing these same materials are alerted to the problem. It can take some time for the implicated material(s) to be identified and it may also be the case that different materials processed on the same manufacturing lines will be affected. Only through detailed investigation will these other materials be identified.

Notification by Authorities and Rapid Alert Systems

Disease Surveillance

Methods for investigation and data collection related to cases of foodborne illness vary from country to country. In some

countries/regions, methods are relatively sophisticated with coordination being carried out at a national level, whereas in many other countries, collection of data and reporting of illness are more limited and often nonexistent. The tools with which public health professionals can identify and track foodborne disease outbreaks have been improved dramatically in recent years but only a few countries are able to take advantage of these developments. The development of 'fingerprinting' (typing) methods and national and international databases can allow cases of illness to be linked and the vehicle of infection to be identified much more easily than has been possible in the past, over wide geographic areas. These surveillance activities rely on good reporting systems, central coordination of data collection and analysis, and good communication between local and national authorities.

Outbreaks of foodborne illness in developed countries are usually followed up by local authorities. In these investigations, basic clinical and demographic details are obtained, together with food histories and other exposure details (e.g., foreign travel and exposure to recreational water) from each case. In some cases, analysis of clinical samples provides additional microbiological information on the causative agent. Much of the data collected is related to bacterial foodborne infections/intoxications, where isolation/characterization/typing methods are more readily available, compared with viral and parasite infections. It is not unusual for infectious disease information to be collected separately from toxinogenic-related illness data. Requirements for reporting/recording illness related to bacterial pathogens differ from country to country.

In case–control studies, cases are interviewed to develop a hypothesis and then cases and controls are interviewed using a tailored questionnaire. Differences between the case and control groups are used to identify the cause of the outbreak. Cohort studies are used to investigate illnesses among people who attended a particular event and everyone involved is asked about what they ate to see if links can be made between a food and the illness.

Very often, clinical samples taken from cases of infectious intestinal disease are negative for pathogens. Sentinel surveillance programs use more general information from general practitioners/physicians, which record the total number of patients presenting with intestinal disease symptoms. Syndrome (such as bloody diarrhea or vomiting) surveillance is another method that can be used for investigation of foodborne illness where organisms are not recovered.

Sporadic cases of illness are much less frequently investigated. The follow-up of sporadic cases of foodborne illness is a form of active surveillance that extends information gathered through passive surveillance systems. Data are gathered from postal questionnaires, personal interviews, or telephone questionnaires. These additional data-gathering exercises could help determine modes of transmission, risk factors associated with the disease, and detect outbreaks.

Laboratory surveillance is actually one of the key methods for the detection of isolated cases of foodborne disease being part of the same cluster, that is, related to the same source. Such a system is particularly important in detecting outbreaks related to industrially produced foods. This was the method that led to the detection of several major multistate or international outbreaks (Borgdorff and Motarjemi, 1997).

Surveillance of Foods

Public health authorities occasionally carry out microbiological surveys of foods, looking for the presence of particular pathogens. These surveys provide a 'snapshot' of the situation with the particular foods targeted. Some public health authorities use the information collected in these surveys to identify particular foods that may pose a greater risk to human health. In rare cases, these surveillance studies have resulted in incidents being identified, where presence of pathogens at harmful levels is reported.

Rapid Alert Systems

In some regions, rapid alert systems can be an important initial vehicle for identifying an incident. For example, the Rapid Alert System for Foods and Food Products in Europe provides information on incidents reported in different member states. For incidents that involve more than one country, the International Food Safety Authorities Network coordinated by the WHO and Food and Agriculture Organization aims to promote the rapid exchange of information during a food safety-related event.

Incident Investigation

The main purposes of an incident investigation are to define the problem and then decide what actions are needed in relation to the affected product in the market, or in distribution and what action is needed for the company to resume manufacture. The company contact should obtain information before any further data are generated. It is important to know what actions have been taken so far, and the basis of these actions should also be known. It is also important to focus on the facts and not to jump to conclusions at an early stage.

In most countries, there are procedures that must be followed in the event of incidents and these will often involve notification to relevant authorities as early as possible, even if this is only a potential incident. The company must be prepared to share all relevant information in an open and timely manner. Where these hazards have the potential to cause serious harm to consumers, the affected products should be withdrawn from sale and where necessary, recalled from the homes of consumers as quickly as possible.

For microbiological incidents, key information is required to estimate the risk to consumers. If there is an immediate threat to consumer safety, action should be taken immediately to minimize the risk to consumers. The information required to estimate risk includes the nature of pathogens/toxins involved, the rate or frequency of contamination, the subpopulations exposed to the hazards, vulnerability of these subpopulations, the quantity and distribution of the particular food affected, other foods that may be affected (e.g., produced in the same factory as the implicated food), food preparation instructions, and thus potential for consumer illness. Incident investigations generally provide a much clearer picture of the scale of a problem and can also point to likely or possible causes. For example, initial information concerning swollen packs will provide data on the rate of contamination from visual examination of packs but does not necessarily provide a true account of this. If packs are contaminated with different

types of microorganisms or if packs are exposed to different storage conditions, then some packs may appear to be unaffected. The actual rate of contamination (e.g., % packs contaminated) in these circumstances can only be determined through more detailed examination of pack contents, which will often involve opening packs and carrying out further tests, including physical measurements, such as pH and microbiological tests. Following such examinations, it is often the case that the frequency of contamination is greater than initially thought and this can have a significant impact on the risk to consumers or to the brand. The type of contaminants can also provide valuable information. If, for example, there are only spore-formers growing in a contaminated product, this may point to a thermal process failure or contamination source inline following application of a sterilization treatment. If there are nonspore-forming microbes growing in a contaminated inline heat-processed product, this is indicative of postprocess contamination and may point to a failure in pack decontamination, a problem during filling or a failure in pack integrity caused by poorly manufactured packs or damage during distribution/storage.

Gathering Initial Company Information

The first step of the incident investigation process is to gather information relating to the affected product for further testing purposes, such as where this is, in what state this is in, how it is stored, is it all under control, and if there is any third party interest in the material, for example, public health authority or independent testing laboratory. Concerning any samples tested so far, it is important to understand how these samples were drawn, how big the samples are, how these were handled, where these samples are stored, how they are stored, what analyses have been carried out, what methods were used to carry out the tests, and by whom these were carried out. This gives an indication of how reliable the initial information may be and how much confidence there may be in this information. For example, there may be potential for contamination and there is also a possibility that storage conditions may impact on the results. It is good practice to store some portion of affected product frozen, for independent analysis. The methods of analysis used should be thoroughly validated for the food tested before use and preferably should be standard methods. On some occasions, particularly when microbiological testing is carried out, testing laboratories will apply rapid alternative methods that may not have been properly validated for the product tested. These rapid methods include polymerase chain reaction tests where the gene targets selected may be shared by a wider group of organisms than the intended pathogen. The laboratory carrying out the tests should be applying sound QA principles.

At this stage it is possible that the problem has already been defined (initial hypothesis) by other bodies and if this is the case, then this need to be verified. To do this, it is often necessary to design an action plan. The purpose of the action plan needs to be defined, timings need to be clearly understood, protocols, responsibilities, and methods of interpretation all need to be agreed before any further testing takes place. To reiterate, it is important not to jump to conclusions on the basis of limited information. For example, the cause of swollen packs may be assumed to be microbiological (gas production by contaminating microorganisms) but gas production may also be caused by chemical reaction within the pack, for example, from pack contents coming into contact with defective inner layers of packaging material, from release of dissolved gases in the pack contents, or change of temperature leading to expansion of gas.

In the design of the action plan, the following should be considered:

- Define options,
- Build a decision matrix,
- Agreement on sampling protocol,
- Agreement on analytical protocol(s),
- Agreement on handling protocol (from sample unit to analytical unit),
- Agreement on responsibilities,
- Agreement on timing, and
- Agreement on interim actions for 'at-risk' material.

Analysis of Initial Information

The next step is to analyze existing data and this may include QA or QC data, data from the market place, and data from the supply chain. For QA/QC data, it is important to acquire all available data and then analyze historical and current data relevant to the 'at-risk' period. The analysis should look for trends/abnormalities in the data and it is essential that data analyzed go back far enough to a period of 'normal' performance so that the baseline can be established. It is sometimes the case that a failure in manufacturing has been continuing for a long period of time and that analysis of the data does not show any 'abnormality' simply because the true background or baseline has not been properly established. To analyze these data, a number of tools are available. These tools are commonly used during manufacturing to trigger alerts when processes deviate to ensure that they remain in control. Such tools can also aid in incident investigation to identify when processes develop to 'out-of control' situations and are important for correctly identifying the 'at-risk' period and product manufactured during this period. These are commonly referred to as Statistical Process Control tools and include histograms, check sheets, Pareto charts, cause and effect diagrams, defect concentration diagrams, scatter diagrams, Shewart charts, and Cusum analysis. Cusum is particularly useful for identifying small but significant shifts in data, such as pH of a product (where pH is a critical control point), where cumulative sums of deviations of sample values from a target value are estimated.

Data from the market place includes complaints, rejects from retail or distribution, storage controls, information from sorting, resorting, and repalletization activities, customer/distribution patterns, and seasonality. Data from the supply chain includes obtaining an 'incident log' for manufacturing over the 'at-risk' period and previous times, checking line performance data (e.g., line efficiency, raw material changes, rework activities, and rejection rates) and preparing a log of corrective actions for the same period. Important information

that is not formally recorded and that can help identify unusual occurrences during production can be gleaned by interviewing operators and other plant personnel.

All of these data should then be assembled. At this stage, it is relevant to consider the following:

1. If the data are consistent with the initial hypothesis;
2. Whether the data are consistent with each other;
3. Whether an 'at-risk' period can be defined; and
4. If corrective action be specified for any retained material and for future production.

Sampling Protocol for New Data

For new data that will be generated, it is necessary to consider lot integrity, sample types, sample handling, and sample coding. For lot integrity, this refers to the relationship between lot, batch, and coding; understanding how to interpret all codes; and deciding how lot integrity will be maintained. For sample type, this considers random versus nonrandom samples, use of multiple level samples, the role and source of controls, and commercial impact of the sampling protocol. For sample handling, speed and cost of investigation and storage and handling are key considerations.

Analysis

New data can include sensory data, results from simple physical measurements and specialist testing that is targeted. Sensory information covers all observations using sight, odor, touch, and (on occasion) sound, for example, tap tone for canned foods. Taste is rarely an option where microbiological contamination or chemical contamination is suspected. For sensory analysis, all investigators must agree a common sensory vocabulary and (where appropriate) the investigator should be trained. For simple physical testing, such testing can be carried out first, for example, weight, color, pressure, pH, viscosity, and microscopy. The investigation procedure should seek interpretation of data at this stage and check if the working hypothesis is still relevant. In addition, the relevance of the proposed analytical method(s) should also be checked and the results obtained so far are reasonable. The working hypothesis is formed using available information, such as the nature of the defect, nature of complaints (if any), nature of symptoms reported, and so on. As mentioned in Section Incident Investigation, it is important not to jump to conclusions too quickly where a potential cause of a problem may get overlooked. For example, some symptoms of illness such as vomiting may be caused by chemical hazards, such as phytohemagglutinins present in uncooked kidney beans, although presence of microbiological hazards such as staphylococcal enterotoxins may be initially suspected. There are a number of sources available describing typical symptoms associated with both chemical and microbiological hazards (see Further Reading).

Where specialist analysis is required, the following are key considerations:

- Identify analyses that require specialist intervention
- Where can the analyses be done?
  - Competence of the testing facility,
  - Facilities,
  - Trust, and
  - Security

  Is there knowledge to interpret the data?

For targeted testing, the following considerations are important:

- Choose analyses to test the hypothesis;
- It is rarely efficient to start with a 'scatter gun' approach to the investigation;
- If a hypothesis cannot be formed then either there is a lack of expertise or more time needs to be spent on understanding before further analysis should be undertaken;
- The limitations of the analysis should be understood.

For recording new data, there should be an agreement on how records/results will be maintained, who is responsible for recording this information, how and where all material under analytical investigation will be retained, and rules for disposal of material under analytical investigation.

For interpretation, it is critical to ensure that the implications of the result to the analytic unit are first understood, and then move on to putting this into the context of the issue, for example, implications of finding a contaminant. The analyst is often not the person to put the finding into context and interpretation involves intimate understanding of the sample (physical and mathematical characteristics). Controls are paramount.

Other Outputs

Other outputs that can provide useful additional information for an incident include QA/QC and supply chain data and information from external agencies, such as regulatory bodies and public health authorities. The proper role of QA/QC (if any) needs to be defined and should consider its effectiveness, use for trend analysis or lot definition, and cost effectiveness. For supply chain–related information, the supply chain manager should be supported to design the most cost-effective and safe management system – never assume that this involves offline analysis.

Regulatory agencies can be a valuable resource and source of expert knowledge and skills. For regulatory-related information, this may include knowledge of incident impact on consumers, specialist sources of information or expertise, or specialist analytical capabilities (e.g., reference laboratories). Importantly, regulatory bodies in different countries may have a particular view on risk posed by hazards in food products, where a hazard-based approach is taken rather than a risk-based approach, for example, presence of mold or bacterial spores in dry products.

Actions to be Taken

It is important that the appropriate action is taken to reduce any risk that is posed by product in the market. These actions include public recall, which is normally the default action taken for consumer safety issues, but is also an option for significant quality issues. Alternatively, silent or trade recalls may be appropriate where relatively minor quality noncompliances occur. In some cases, no further action may be

required, for example, where there are minute deviations, or very small quantities involved (e.g., at the end of shelf life) or where there are no consumer complaints.

Communication with the Consumer and Other Stakeholders

Communication with the media and public must be carried out in an effective manner and must be well managed. Risk communication is one of the key elements of risk analysis, together with risk assessment and management. This needs to consider perceived risks and real risks. Any communications must be properly prepared and the company should stand by any statements made. It is often useful to anticipate the reaction from consumers and prepare questions and answers. Any communications must include a clear description of:

- the action being taken (e.g., product recall);
- the product(s) affected;
- what the problem is;
- what the consumer should do, for example, check dates on packs of affected product and instructions to return packs;
- information related to other products not affected;
- an apology;
- further information, such as a toll-free careline phone number.

Questions and answers should anticipate on a broad variety of questions coming from different stakeholders. These stakeholders include consumers (and their organizations), trade partners, authorities, the media, and the workforce of the company.

Identification of Direct and Underlying (Root) Causes

The direct causes of the incident may already be identified in the early stages of an incident or may become apparent during the investigation. The direct causes can be categorized according to where the failures occur, such as raw material supply (supplier), product/process design, manufacturing, or distribution/storage. In some cases, the direct cause may not be immediately obvious or clear and it may be necessary to gather more information, for example, through interviews of personnel who may have knowledge of what occurred, and whether anything changed to cause the incident. For processed food products, the primary causes tend to occur during manufacturing, raw material supply and, to a lesser extent, in product/process design. The direct causes can be subdivided into substandard acts or substandard conditions, and these are often attributed to human error. Substandard acts include failure to follow procedures, policies, or good practice; failure to identify hazards and risks; and failure to check/monitor. Substandard conditions include defective or poorly maintained equipment, defective materials, inadequate instructions or procedures, inadequate information or data, inadequate preparation or planning, inadequate support or assistance, and inadequate communication or systems/processes.

The major underlying or root causes for food incidents involving microbiological hazards may be classified according to the following:

1. Quality management system failure;
2. Hygiene management system failure;
3. Plant design standards;
4. Product and packaging design;
5. Cleaning and disinfection; and
6. Raw material supply.

These underlying causes may be linked to lack of knowledge, skill, or experience; inadequate leadership or supervision; inadequate maintenance; or other factors. It is important that all of the underlying causes are properly identified so that effective and appropriate corrective actions can be taken. Tools that can aid in the identification of direct causes and link these to underlying causes include the systematic cause analysis technique, 'fishbone' analyses, fault tree analysis, and failure modes and effect analysis. Although many of these tools were designed to identify underlying causes of engineering failures or occupational safety incidents, their principles can be applied in the context of consumer incident investigations.

Recall Systems and Disposal of Food

P Overbosch and J Carter, Metro Cash & Carry, Düsseldorf, Germany

Background and Scope

As food farming, manufacturing, retailing, and distribution become more mature around the world, consumers increase their knowledge of both of 'what can go wrong' in food products and their awareness of their personal rights. At the same time, the technical ability to detect noncompliance improves. When something does go wrong and a product is defective, it is often necessary to remove the item from sale. These two conditions have led to food recalls becoming more common in many countries in recent years. For example, the European Union Rapid Alert System for Food and Feed, known as RASFF, records and communicates several thousands of cases every year – with an upward trend – and in America both the US Department of Agriculture's Food Safety and Inspection Service (FSIS) and the Food and Drug Administration (FDA) maintain an ongoing summary of current recalls. There are still countries that are far less familiar with recalls, but the practice of informing customers and the general public about safety or legal concerns involving specific products – with the request not to use the product and return it or dispose of it – has spread very rapidly during the past decades.

In this article, the principles and organizational aspects of recall and disposal of food, from the perspective of a food manufacturer, food service provider, or retailer, will be covered, illustrated with some examples where appropriate.

Withdrawals and Recalls

Even with an efficient quality assurance (QA) system, there may be times that a company's products do not meet quality and safety criteria and the company has to take actions, so all QA systems will need to include an effective Incident Management System.

Below, the organization and decision process around recalls and withdrawals will be discussed, but at this stage, it is helpful to clearly distinguish between the two.

- A withdrawal involves the removal of product from that part of the supply chain that is within the company's direct control (definitions may be used differently in different countries, see e.g. the Australian/New Zealand document on recalls: http://www.foodstandards.gov.au/_srcfiles/Food%20Recall_WEB.pdf). That may include in-house storage, own trucks or warehouses, or even (from a retailer's perspective) store shelves. A withdrawal does not necessarily mean that no product has reached customers or consumers, it means just that it is not deemed necessary to inform the general public. A withdrawal may always be sufficient if there is a certainty that all products can be accounted for (nothing out of the company's control, meaning nothing could have reached the customer and cause harm) or when the defect is considered to be minor (small misprint on the label or a situation that might cause a somewhat higher rate of complaints but no more) and a recall is seen as disproportionate. Where there is any danger to public health, a withdrawal can only be justified if the product is entirely within the company's control and is fully accounted for; in other words, it is carried out as efficiently as a recall, with enough resources dedicated by the company to ensure total product removal in a timely period.
- Instead of going public, companies sometimes consider a 'silent recall,' which means that product is recalled from professional customers only (e.g., a manufacturer requests retailers to take products off the shelves but does not inform the general public), but this form has become rarer in recent years. Authorities in many countries need to be informed about product defects, and where there is sufficient cause to withdraw products from shelves, they will normally conclude that there is sufficient cause to inform the public.
- A recall (sometimes known as a 'public recall' or 'consumer recall') is then the most radical step to regain control over a product issue, informing the general public and the competent authorities and providing instructions on how to handle the situation. Typically, recalls are indicated in situations where products (are expected to) give rise to unacceptable risks to users, constitute major legal nonconformities, and/or where a recall is mandated by authorities.
- For products with undeclared allergens, some governments may accept a public information rather than a public recall.

The Elements of an Incident Management System

Structural Elements

Effective handling of a food safety or compliance situation requires systematic preparation. Companies will, therefore,

need to develop a standard procedure, which will typically involve the following elements:

- A company policy may typically state the intention to protect their customers, employees, and the general public against negative impact on their health, safety or security, the environment against pollution, their brands, operations, and the company as a whole against legal liabilities and/or damage to property or reputation, and in order to assure business continuity and limit financial damages where possible. This covers the scope and the order of priorities of the incident management system.
- Organizational principles and responsibilities: Individuals and functions carrying specific responsibilities in an incident situation need to be defined. This normally involves nominating a focused team, often called an Incident Management Team (IMT) or similar, with a small number of core members (for our current purposes that would be QA, Legal Counsel, and Communications) and additional support roles where needed. For companies with multiple sites, the structure at sites or country organizations need to be defined, as well as the relative responsibilities (Head Office may be in the lead, or incidents get managed primarily locally, or the location of the responsibility will depend on the scope and seriousness of the issue.).
- Facilities: the IMT and its members must have adequate meeting and communication facilities. This includes: a meeting room that is/can be made permanently available and accessible also outside office hours, with TV, a telephone with telephone conference capabilities (ideally with a 'mute all' button), and computer network/internet connections (also for social media tracking). Individual members (or their appointed backups) need to be reachable at all times through telephone and e-mail.
- A notification procedure, assuring that the appropriate information is forwarded to the IMT as early as possible. The notification procedure needs to include some simple escalation rules in order to assure the necessary information – and only that – getting notified immediately to the IMT. Escalation rules may include triggers like: two or more complaints of illness relating to the same product/batch code, one very serious complaint (clear danger to health and hospitalization), one case of allergen mislabeling, report of product tampering, etc. Experience indicates that no escalation system works perfectly; there will always be 'false positives' (notifications to the IMT that on balance did not require IMT attention) and 'false negatives' (issues that should have been notified but were not). It is the responsibility of the IMT to monitor and manage the balance on an ongoing basis. Maintaining a low but steady level of false positives is probably where the optimum lies in practice. In other words, it is better to overcommunicate – even in the case of a false positive, advice can be invaluable and trust develops between business units and the IMT. The wise and experienced counsel of a central 'node' of communication can often be used to reduce panic and disseminate best practices in a complex organization.
- Training needs to be organized for all involved, in order to assure an up to date understanding of the internal procedure and its specific requirements for every individual's position. Typically included in training are: (1) awareness for all employees, including their responsibility to alert the IMT (directly of otherwise, as appropriate in the specific company environment) of any situation that has the potential to require a withdrawal or recall, (2) specialized instructions for the 'first line responders,' i.e., company telephone, reception, or customer service personnel, and (3) satellite IMTs (if any).
- Communication within the different divisions of a company is important because a recall decision in one country may occasionally differ from a decision in another. This is often a contrast between developed and developing markets, certainly where traditional trade is involved. Clearly, this will not apply in the case of FDA Class 1 type situations. However, qualitative issues require awareness of local market sensitivity, the local legal environment, and the awareness of what a recall is for.
- Product testing during incidents needs to be very carefully managed. In the context of incidents, testing should exclusively be carried out where it is necessary, conclusive, and will uniquely and decisively enable the company to take and/or – where necessary – explain and defend decisions. The testing methodology used must be recognized as valid (i.e., it actually measures the parameter of interest), sufficiently sensitive (able to detect/quantify the parameter at levels relevant to the issue), and reliable (repeatable, reproducible, and unlikely to give false positives or negatives), and approved testing facilities must be available. Furthermore, the company should be prepared for the full range of potential outcomes of the analysis before having their products tested. Typical pitfalls include:
  - Testing of unrepresentative or uncontrolled samples (testing leftovers from a restaurant may reveal the occurrence of a pathogen but is unlikely to decisively point to a root cause).
  - Testing aimed to clear product that has failed a test before ('you cannot test your way out of a positive'), which may only lead to confusion and delays.
  - Testing in the absence of a realistic concern (e.g., bovine spongiform encephalopathy (BSE) testing of beef material originating from a certified BSE-free country), which only incurs the risk of false positives.
  - Testing without a clear objective or specific purpose, which may end up raising entirely unrelated uncertainties/suspicions. (It is wise to pose the question in advance – 'what will we do with the results?')
  - Testing at nonapproved labs and in the absence of clear confidentiality agreements. In many countries, laboratories are obliged to inform authorities if they find evidence of unsafe or noncompliant product, but it must always be clear what a lab may communicate to others (nonauthority) and what will be subject to confidentiality.
- Communication between manufacturers, food service providers, and retailers: in any recall situation, removing noncompliant product from distribution requires teamwork between the makers and the distributors of the product. It is helpful to have this agreed in advance of

any cooperation; key contacts should be agreed, obligations for communication defined (often contractually), and standard statements and templates prepared in advance. Some retailers, particularly in traditional trade environments in developing countries, may not be completely diligent in removing offending product from their shelves, and it requires active engagement from the manufacturing company to physically remove product, using the sales force on the ground ('putting sales into reverse'). Indeed, anecdotal evidence suggests that with a 'public recall,' the percentage retrieval of noncompliant product is surprisingly low (perhaps 10%?), whereas with an engaged 'reverse sales' team, much closer to 100% of implicated lots maybe removed from sale.

- Incident classification systems are used in two ways: (1) a priori systems, where an incident is classified according to its potential to do harm, and the incident management is based on this classification. This approach may provide firm guidance in specific situations ('if the situation has *xyz* characteristics, a recall will always be done'), but the downside is that classifications may change over time, and some companies are uncomfortable with a priori limiting their options. Many companies, therefore, use (2) an a posteriori system, whereby the incident only gets classified after the active phase is over, on the basis of its characteristics (microbiology related, allergy, etc.) and the impact it has had (actual harm caused, damages, media involvement, authority reaction, etc.). The purpose of the a posteriori system is then to facilitate 'lessons learned' exercises and enable trend analyses over time. The FDA has developed a widely used system, primarily for a priori classification, which then guides the:
  - Depth of recall, i.e., extending to the consumer or user level, the retail level, or the wholesale level.
  - Public warning; local, national, targeted to specific groups, etc.
  - Effectiveness check (an assessment of how effectively the recall was communicated, understood, and actioned by relevant stakeholders).

The above topics all need to be discussed, defined, and communicated – and the relevant staff trained – before and separately from the management of an actual incident in order to give clear guidance and prevent time consuming internal discussions at the most inappropriate moment.

Early Warning

Complaints

It is clear that the earlier a company is informed about a problem, the more it can do to prevent harm and damage, and the better are its chances to limit the scope of a recall or withdrawal. Therefore, the company will want to start with putting an effective customer inquiry and complaint system in place. To these authors' experience, food complaints typically range from less than one per million units sold to a hundred or sometimes more than that, for processed food, depending on the geography (complaint culture) and the type of food (coated nuts typically contain more foreign material objects than refined sugar). Complaints are an invaluable source of early warning that something may be amiss and they need to be recorded and (trend) analyzed very carefully. Being able to pick up unusual complaints and investigate them as soon as they occur may save lives (as these authors have witnessed in a 'may contain' allergen case). Not every complaint needs to lead to a recall or withdrawal, and not every recall is preceded by a complaint, but in a very large number of cases, there are warning signals that can be used to prevent things from escalating. Operating an effective complaint system will in most cases imply having a call service available, with clear instructions on how to recognize and escalate serious or suspicious complaints, covering the appropriate opening hours (which may be somewhat outside normal working hours) and managing the percentage of 'missed calls' to a minimum.

These days, the challenges of social media mean that the definition of a 'complaint' is blurring. In the past, companies could glean information on the 'stock-keeping unit' (SKU), lot code, nature of the issue, etc., directly from the complainant, whereas now a serious issue may be posted in real time via Facebook, YouTube, or Twitter without the opportunity for a producer or retailer to respond appropriately. The potential impact to brand integrity and consumer perception of the company is significant. Nevertheless, any challenge brings with it opportunities: if a company is in doubt on the seriousness or scope of a problem, a search of social media sites is useful in establishing whether consumers are chattering or even aware of the issue.

External Information

Incidents may be homegrown, but they may also be imported. Companies have the possibility to scan a wide range of news media for signs of trouble, which may involve, for example, a source of raw materials getting associated with an issue (e.g., various dioxin contamination cases over the past few years in Europe). Other sources of information could be, for example, a recall being announced by a supplier with whom they do business (or a competitor who sources their product from the same supplier), news about professional partners losing their food safety or quality certificates, or trends communicated by authorities and established laboratories.

Having an early warning system in place, continuously monitoring internal and external signals, is an essential element in an incident management system, which can facilitate a damage limiting early response. Trade organizations such as FoodDrinkEurope (previously known as CIAA, *Confédération des Industries Agro-Alimentaires de l'UE*) in Europe and in the US, the Grocery Manufacturers Association (GMA) can have a very useful role in this.

Traceability

Food law in many countries requires traceability systems to be in place – generally on the 'one step forward, one step back' principle. Where decisions need to be made regarding withdrawal and recall, having exact traceability in place – with all information readily accessible – is a decisive factor in determining the nature and scope of the retrieval action.

For manufacturers, it is important to define upfront for all their raw materials and ingredients as well as for their internal processes, what the appropriate definition of a 'batch' is. Formally, a batch represents a quantity of materials produced under the same conditions, but in practice, things may be quite complex and batches may not always be as homogeneous as expected. Root cause investigations may be facilitated by production time coding, which can then be correlated with other timed events (equipment or power breakdown, incidents on the line, changeover to another batch of ingredients, etc.), but for retrieval purposes, a date code is normally used. When a failure is detected in time, the availability of complete and reliable traceability data may make the difference between a withdrawal and a recall (is all affected product still under our control?) and between recalls in one country or more (do we know exactly where this product was shipped and whether it is already on the market in each of these countries?). Linking internal traceability to root cause elucidation may make the difference between recalling one date code and 'everything on the market.'

Where an EU rapid alert has been issued, the competent authorities may request to be informed about both the whereabouts of the product (sometimes well beyond the on-up-one-down requirement) and the actions taken. Up to three countries may often be involved, including:

1. where the product defect was originally found and communicated,
2. where the product was made, and
3. where the multinational sales company has its legal residence.

Traceability in all these cases then explicitly includes the ability to account for the entire affected volume. Where products have been sold to known individual customers – as is the case with professional wholesalers – the integrity of the traceability system may allow for the above mentioned 'silent recall,' where all customers are informed, but the general public is not. In most cases, however, there is a possibility that the products were sold on to the general public and these cases generally end in doing both: informing the customers directly and informing the general public through the media.

Traceability requirements, however, are not restricted only to materials, products, production conditions, and distribution. Effective retrieval management also requires a 'traceability' of key stakeholders. For the incident management procedure, the company will need names, addresses, contact numbers, and clear agreements on accessibility at all times for:

- Incident management team members and internal support functions.
- All other functions within the company that need to provide information and/or take action.
- External support resources (laboratories, medical, and toxicological expertise).
- Competent authorities (food and health authorities and sometimes also police and emergency services).
- Business partners (suppliers, customers, and logistics providers).
- Media.

Managing Recall, Withdrawal, and Disposal of Food

Communicating and implementing a decision to retrieve product will involve a number of elements:

- What to retrieve – this will involve a very clear and precise description, preferably accompanied by pictures of the product(s) involved: brand, type of product, type of packaging, volume/weight, and date (production or best before). Trade companies typically have a standard form for this purpose, assuring completeness of the information and supporting a standardized process. When communicating with the general public, the emphasis needs to be on how people can recognize the product in question, involving usually front/back of pack pictures. Communication routes include traditional media such as newspapers, radio, and TV, but increasingly, shopper loyalty scheme information together with internet or phone campaigns may be used.
- Why it is being retrieved – the relevant detail here may depend on the audience. Communication with authorities may involve a greater level of technical detail than an internal retrieval order at a retailer or a media release intended for the general public. Specific warnings for target groups (allergic, immunocompromised, etc.) can be part of this communication.
- What people who already have used (eaten) the product should do – this depends entirely on the nature of the issue. Companies should normally not provide medical advice (they are not medical institutions) but refer concerned consumers to available medical services. This may include a brief summary of realistic expectations such as a description of illness symptoms and advice to see a doctor if these occur. Where the situation demands and geographical distribution permits, companies may organize medical support for their customers. Care must be taken to respect privacy and medical confidentiality in these cases.
- What the public should do with the product – when the public is informed, the advice is always not to use the product but to either discard it (if this can be safely and definitively done without harming the environment) or return it to the point of sale or any other facility mentioned, for a full refund. When the advice is to destroy the product and not return it, the mechanism for obtaining the refund should also be made clear.
- What people should do if they have questions – normally, this will involve a telephone service, with a standard list of frequently asked questions and their answers. Experts (e.g., medics) should be available to deal with questions outside the standard list and update/refine the list as needed.
- How the product should be collected and stored. This may be different for withdrawal and recall situations. Withdrawals may be carried out on a purely precautionary basis, with the expectation that subsequent investigation may clear the product and it may be returned into circulation. In those cases, withdrawn product must be separated, marked, registered as 'on hold, not to be distributed' and monitored for integrity on a regular basis. Where retail organizations issue a withdrawal notification internally, they typically require both a confirmation of reception

from their stores and a return notification of the withdrawal having been completed, including quantities. Recalls, however, are normally seen as irreversible – once a product is recalled, and the general public is informed about the issue and the reasons not to use the product, the batch(es) can never get back into circulation. For internal handling purposes, they, therefore, need to be completely separated as quickly as possible, and using off-site storage space that is not used for distribution purposes and is sufficiently guarded is recommended. At the same time, the product still needs to be clearly labeled as 'on hold, not to be distributed' and stock counts should be carried out at regular intervals until final disposition. Over the years, there have been several cases of recalled product that inadvertently got back into circulation, posing a risk to consumers, damaging the brand, a situation deeply embarrassing for all involved.

- How the recalled product should be destroyed. Destruction needs to be:
  - Irreversible – there have been cases where product that went into landfill was dug up and redistributed later. It also means that not only the content but also the packaging material must be put beyond salvage – there have been cases where glass jars and caps, with their labels and prints, have been salvaged from general waste dumps and reused for counterfeit purposes.
  - Complete. Destruction of the entire recalled product needs to be assured and recorded. That may also involve affected raw materials which formally were never part of the recall. Also, in some cases, a recall will mean the commercial end of a product and there may still be unused packaging – sometimes at a supplier's site. In case the packaging material and labels will no longer be used, they also must be destroyed in this context, along with the specific tools or printing matrices used for their production.
  - Safe for the people involved and for the environment.
  - Witnessed and recorded – fraud in these circumstances may be a sudden and relatively large opportunity. Depending on the local level of confidence, a company may want to take very specific measures to assure effective and complete destruction. This applies especially when the product in question remains visually acceptable.
  - Timely. The longer the defective and recalled product is stored, the higher the chance that it will find its way to the market (within the country or elsewhere).
  - In accordance with local authorities' requirements. Authorities in various countries have strict regulations on the destruction of food products, and they may set time limits, require specific methods, and may want to supervise destruction directly.
  - Officially terminated. When all products and materials have been accounted for – or when the recall can reasonably be considered to have achieved its purposes, i.e., to inform all stakeholders, prevent them now and in the future from using this particular batch of product and retrieve and secure (destroy) all products that were originally released – the recall must be formally terminated. Terminating a recall does not involve a notification to the general public, but it does require a close-out notification to those who have been professionally involved (warehouse, logistics, call center, etc.).
  - Evaluated and reported. After a recall, the Incident management team must assess the handling of the situation and lessons learned, including root cause and improvement actions. The evaluation may also typically include a product recovery percentage as demanded by authorities in some countries. Recovery rates for recalls will rarely, if ever, reach 100%. Some products will have been consumed, some consumers will not be aware despite all communication efforts, and some may not be interested. A common cause of recall is allergen-related mislabelling, and nonallergic consumers are likely to simply ignore those recalls, thereby driving down product recovery rates. As mentioned above, those companies that have defined an a posteriori incident classification scheme will conclude their final rating at this stage.

In summary, preparing for withdrawals and recalls is an integral part of any quality management system. A basic purpose of the quality assurance (QA) system is to avoid these situations, but in practice, any organization will at some point in time face the need to make rational, science-based decisions, and act as pragmatically as possible in order to protect the general public and their own reputation. An effective system will not only require preparation, training, and clear structures, roles and responsibilities, but also a company culture that is ethically strong. Companies with robust practices and discipline will be rewarded with the trust and confidence of all stakeholders across the value chain.

FOOD SAFETY ASSURANCE SYSTEMS

Tampering

E Norman, Reading Scientific Services Ltd, Reading, UK
G Coulam, Thatcham, UK
K Masters, Reading Scientific Services Ltd, Reading, UK

Introduction

By dictionary definition, tampering could be considered as any act of meddling or interfering with any given item. However, within the food industry, the word has come to have a particular association with extortion, blackmail, and deliberate attempt to damage the safety or palatability of a food product, and/or to undermine the reputation and commercial viability of the food manufacturer.

The act of tampering is generally seen as something done to the finished product, perhaps following legitimate purchase, with the product being returned to the shelves for sale to an unsuspecting victim. That said, there is no reason to dismiss the possibility that someone, such as a disgruntled employee or disaffected supplier, might also tamper with raw ingredients or even the machinery on the production line, in order to create similar problems for the manufacturer.

Such acts should be seen as being different from deliberate adulteration of ingredients, both in scale and motivation. In the case of adulteration, a cheaper ingredient is usually substituted for a more expensive one (e.g., adding rape oil to olive oil). Alternatively, attempts are made to disguise the inferior quality of an ingredient by addition of an illegal and/or undeclared substance (e.g., melamine in milk and Sudan Red I in spices). In neither instance of adulteration is the perpetrator likely to draw attention to his crime. In the case of tampering, the perpetrator will certainly seek or threaten publicity, and may even eschew carrying out the act of tamper in favor of merely threatening or claiming to carry it out. Whether the tamper actually happens or not may be of little consequence if the motive is to create fear and suspicion of a product in the hope of achieving some financial gain.

Of course, for the manufacturer to make the appropriate response, it matters to know whether the tampering has occurred or not, and whether the threat is as great as the perpetrator intends to imply. After all, the perpetrator may threaten something that is not possible in practice, or that may not be especially serious, as will be discussed below.

The Extent of the Problem

It is difficult to obtain exact figures on the extent of the tampering problem within the UK, never mind the whole world. It is undoubtedly one of those crimes where fear of the consequences exceeds the likelihood of an incident. This is understandable given the unpredictable nature of the crime, the entirely random choice of the victim (at least in terms of the ultimate consumer), and the disproportionate extent of the commercial damage that can be caused. It might only need one actual incident of tampering to result in thousands of products having to be recalled.

There are no reliable statistics available to indicate the number of incidents that occur. The Food Standards Agency (FSA) in the UK advises that in the last 5 years (2005–10), there has only been one case where the risk to consumers was assessed to be significant and required action by the Agency at the national level. This was the case of Allied Bakeries receiving five complaints after fragments of glass or sewing needles were reported in Kingsmill sliced bread.

In a press statement issued by Allied Bakeries at the time, the foreign bodies were described as being clearly visible once the bread bag was opened and were not embedded in the bread. Therefore, in agreement with the FSA, the company decided to alert the public and urged consumers to be vigilant. The company also worked with the police to increase security at its Orpington site "in order to minimize the risk of further tampering", clearly indicating that the incidents were viewed as possibly occurring at the factory. Unfortunately, the incidents continued with further alerts being issued in October and December 2006. At the time of writing, no public announcement has been made concerning identification or arrest of the perpetrator(s).

The Office of Criminal Investigation, a division within the US Food and Drug Administration (FDA), was invited to offer their own statistics on the tampering issue but did not do so. However, the office did refer to an arrest in January 2010 of a man who had tampered with the labels of Gatorade, although apparently not with the contents.

Some indication of the scale of the problem might be derived from statistics released by one of the laboratories in the UK that investigates contamination incidents on behalf of food and drink manufacturers. Reading Scientific Services Ltd (RSSL) estimates that in the past few years, approximately ten of its Emergency Response Service (ERS) investigations have arisen due to actual or threat of tampering, out of a total approaching nearly 1000 investigations. If this experience is in anyway typical, it suggests only 1% of product contamination emergencies (foreign body and chemical) are due to tampering. The logical conclusion is that accidental contamination,

factory problems, packaging problems, adulteration, environmental contaminants etc. are much more common.

A review of incidents has indicated how difficult accurate data is to come by, but some companies report hundreds of cases of tampering. Many of these cases go unreported for fear of copycat issues. The majority of these cases are not conceived with the intent to cause harm rather to extort restitution or merely to gain free products from the manufacturers. The review also established that the majority of incidents actually occur at the end of the supply chain, and it is these incidents that have the potential to cause the greatest impact to public health. Of those cases that occurred postdistribution (89 cases over 40 years) 52% were aimed at extortion from either manufacturer or retailer.

Table 1 lists some examples of tamper incidents in different parts of the food chain through recent history. There has been an increasing trend in reporting of incidents. This is thought to be linked to a range of factors including an increase in copycats, technology to track and report such events, and increased recording in China.

Although highly feared and often linked to potential terrorism, only a limited number of cases involve biological agents. This is thought to be partly because of the difficulty in obtaining agents. Generally, perpetrators have ready access to pathogens through work in hospitals or laboratories. The most renowned incident is that of the Rajneesh religious cult tampering of salad bars with *Salmonella*. The majority of the US casualties from biological tampering relate to this instance that was actually thought to be a trial run to see if the group could incapacitate voters.

Radiological contaminants, such as polonium, are also highly feared as potential terrorism agents but are very rare and so far unlinked to true tamper issues, but have been used as an alleged assassination tool (e.g., the Litvenenko case, 2006).

Two Textbook Cases

There are two key cases of tamper from the past 30 years that demonstrate the importance of the issue, and the risks that the food industry must consider seriously.

Hence, the cases affecting Tylenol (not a food product, but relevant nonetheless) and Heinz baby food are offered as examples of deliberate tamper, as well as being cases that changed the way food manufacturers address the issue and try to mitigate the risks.

Tylenol

In 1982, Johnson & Johnson's Tylenol medication, manufactured by its subsidiary, McNeil Consumer Products Co., commanded 35% of the US over-the-counter analgesic market. This represented something like 15% of the company's profits.

During 1982, seven people died after taking Tylenol tablets, which were subsequently found to have been laced with cyanide. The associated publicity is believed to have knocked $1billion off the company's market value, and led to the FDA issuing its tamper-resistant packaging requirements in 1982, and the introduction of the Federal Anti-Tampering Act in 1983 in the USA.

The prime suspect was a certain James William Lewis, an unemployed accountant at the time of the killings, who was sentenced to prison in June 1983 for demanding US$1 million from Johnson & Johnson, "to stop the killing." It transpired that Johnson & Johnson was the former employer of Lewis's wife. However, although Lewis admitted sending the letter demanding money, it must be noted that he has consistently claimed he had nothing to do with the product tampering, and never meant to collect the money.

The incident led to the US FDA introducing the tamper-resistant packing regulations. The Federal Anti-Tampering Act passed in 1983 made it a crime to tamper with any packaged consumer products.

Unfortunately, Johnson & Johnson was targeted in a similar way in 1986. This time the company reacted differently, ordering that Tylenol should be recalled from every outlet and not just those in the state where tampering had been confirmed. The company also decided the product would not be reestablished on the shelves until something had been done to provide better product protection.

As a result, Johnson & Johnson developed new 'tamper proof' packaging for Tylenol, and within 5 months or so, it had recovered 70% of its market share for the drug.

By acting quickly and putting consumer safety ahead of any other consideration, Johnson & Johnson's approach is widely seen as the model for handling all similar product crises.

As a footnote to this case, the Chicago Tribune reported on 05 February 2009 that the Federal Bureau of Investigation (FBI) had reopened the investigation into the seven unsolved murders, and referred to the original investigation as having involved more than 6500 leads, and 400 possible suspects. Almost a year later, in January 2010, Lewis and his wife attended a closed hearing in a Woburn courtroom to determine whether the couple must provide fingerprints and deoxyribonucleic acid (DNA) samples to authorities, presumably to provide evidence that can be analyzed by techniques unavailable in 1982. No further details have thus far been made public, but in May 2011, the FBI is reported to have also sought DNA from so-called 'Unabomber' Theodore Kaczynski as part of this investigation. It could be that the case has a new twist to come.

Heinz Baby Food

The UK's most notorious, and influential, case of tampering was carried out by a former police detective, Rodney Witchelo. His acts included spiking a jar of Heinz baby food with caustic soda, two drawing pins, and a note that threatened more to come. The amount of caustic soda used was sufficient to kill 27 babies, and fortunately, when the purchaser opened the jar (to feed it to her dog), it made her eyes water and alerted her to a serious problem with the product.

Witchelo demanded £3.75 million from Heinz and Pedigree Pet Foods and having demonstrated his ability to tamper products successfully, threatened to flood the shelves with poisoned product.

Table 1 Examples of cases of tamper throughout the food supply chain

Supply chain			
1978, Europe	Oranges	Mercury	Tamper occurred at distribution port, by a Palestinian militant group, tainted citrus fruit showed up in Germany, Spain, Belgium, England, and Morocco
1989, USA	Grapes	Cyanide	A warning call claimed that Chilean fruit had been laced with cyanide, only 2 grapes tested positive. Suspected anti-Chilean government protestors, no injuries but serious economic implications
2006, Australia	Cereals	Glyphosate weedkiller	Spiked in crop spray, visual differences in products, testing carried out, and product recalled before reaching consumers
Retail			
2010, USA	Jell-O pudding	Product replaced with sand and salt	Elderly couple were indicted on multiple counts of petty larceny and tampering, no injuries
2003, USA	Ground beef	Nicotine (pesticide) in ground beef	Supermarket employee tamper, several hospitalizations, no fatalities. Culprit jailed and fined
2003, Italy	Bottled water	Acetone, bleach, or ammonia in bottled water	30 hospitalizations, no culprit identified, suspected anticapitalist activists or eco-terrorists
1984, USA	Girl Scout cookies	Pins, needles, and other foreign objects in boxes of cookies	Resulted in tamper-evident boxes, the FBI concluded the 800 reported incidents were false alarms or copycat cases
1986, UK and USA	Baby food	Glass, razor blades, pins, and caustic soda	An extortion case which resulted in several copycats. Companies involved learned lessons about handling the press relations and regulatory authorities
1976, USA	Foods and pharmaceuticals	Various agents	One culprit part of a larger part of larger campaign designed to cause extortion and terror
1984, Japan	Candy	Cyanide	Complex organized attempt to extort money from the manufacturer, no arrests
Restaurants/food service			
1984, USA	Salad bar	*Salmonella*	Rajneesh incident, up to 751 cases reported
1992, China	Flour	Arsenic	Zhengzhou, 788 cases of arsenic poisoning in a college canteen
1998, Japan	Curry	Arsenic	4 deaths and 63 hospitalized after cook-poisoned food at a summer festival
2002, China	Various hospital foods	Rat poison	Tangshan, 42 deaths and 300 hospitalized in a feud between restaurateurs
2002, China	School food	Arsenic	China, two caterers laced school food injuring 193 in a feud with authorities
2005, Philippines	Cassava fritters	Coumaphos insecticide	Canteen worker laced fritters during cooking to serve to school children, 28 died and 130 injured
2006, Australia	Soup and salad bars at different restaurants	Rat poison	No injuries but the restaurant chain delayed notifying authorities. The case prompted Queensland lawmakers to draft a law requiring that all food establishments report suspected tampering immediately, or face a fine of US$15 000

One characteristic of this case, and one that should worry every food manufacturer, was the number of 'copycat' incidents that it spawned. These included individual consumers chancing their arm in the hope of receiving significant compensation, to other more serious criminals copying the *modus operandum* of Witchelo. RSSL's laboratories were involved in several of these investigations, and noted a very definite peak in foreign body investigations in the period that Witchelo was working.

Sadly, Witchelo's influence continued long after his arrest and conviction in 1990. A letter bomber who tried to blackmail the Tesco supermarket chain, approximately 10 years

later, claimed at his trial that he had been inspired to commit his crimes after reading an account of the police investigation into Witchelo in a magazine. Although his strategy was very different, the basic idea was the same, i.e., to extort money from a well known, profitable, and major business.

His influence may also have extended to the USA. On 27 February 2004, the Office of Criminal Investigations was advised by FDA Emergency Operations of a tampering and extortion complaint received in Cincinnati, OH, USA. Ultimately, a British citizen was convicted of trying to extort $180 000 from a supermarket chain by threatening to place contaminated baby food on store shelves.

Copycats

A direct correlation between the amount of publicity and number of copycat incidents is questionable. Different commentators present different views. However, it is certainly the case that publicity of a specific incident has 'inspired' copycat incidents and prompted false claims from consumers. It is also the case that any such activity merely obscures and confuses the picture concerning the original incident, potentially wasting police time and providing false leads that require investigation.

Prevention and Control Measures

Prevention measures in terms of tampering are not easy to put in place. While tamper proof packaging can protect consumers and manufacturers alike, they can be circumnavigated. Governments and manufacturers have emergency systems or crisis plans designed to protect food, plants, and animals from accidental or intentional events. Such plans will rely in part on surveillance programs and food recall systems. Despite such systems, a product may still be contaminated at any point in the food supply chain, which extends from farms to stores. Food retailers play a vital role in securing the supply chain. They need to be aware of the food purchased, its supply chain, and storage security. For example, the city of New York recommends that even small food retailers and restaurant facilities follow the simple rules in Box 1. So vigilance is perhaps the key, retailers and also consumers should be aware of how to recognize the signs of food tampering, which can be seen in Box 2.

Box 1 Retailers prevention advice:

- Purchase only from reputable vendors. Keep an inventory, know who delivers your food.
- Be familiar with the foods you purchase, prepare, and serve.
- Schedule deliveries when staff are present to inspect and secure the delivery.
- Examine foods before use. Do not use foods with foreign objects or an unusual odor, texture, or appearance.
- Know your employees, run background checks on new employees and keeping them supervised during training, which should include an element of how to recognize signs of tampering.

Several governments and regulatory authorities have recognized the risk to consumers, the increased threat of the use of tampering as a terrorist approach has resulted in the development of advice and guidance for consumers and retailers. One such system is the INK approach shown in Box 3.

Manufacturers need to be prepared, having an effective crisis plan with procedures and systems to deal with product tampering. This will involve access to a multifunctional team that includes personnel from scientific and regulatory affairs, manufacturing, public affairs, sales and marketing, and legal counsel. Key responsibilities such as investigation and reporting to the authorities and press should be defined. The plan should also give ready access to manufacturing and supply chain information to expedite investigations. Most companies now have crisis management plans prepared in advance so that they are better able to cope with this kind of incident. They should also have procedures and systems in

Box 2 Recognizing signs of tamper:

- Packaging that has been opened and resealed;
- products that have damaged or missing safety seals or tamper-evident seals;
- products or packaging that is cut, torn, punctured, or discolored;
- products that are dirty or damaged;
- products with strange odor or flavor;
- cans or jars with signs of leakage, spillage, or corrosion;
- vacuum-packed products with no vacuum seal;
- packaging that has been altered, including labels, product lot codes, and other identifying information; and
- the presence of a foreign object or nonfood item in the product.

Box 3 The INK approach:

- Isolate the food (for retailers or manufacturers investigate – gather evidence)
  - Do not eat any of the food or feed it to livestock or pets.
  - Get medical attention right away if anyone who has had contact with the food feels sick.
  - Do not handle the food more than you need to.
  - Carefully place all the food in a sealable container (even if it is half-eaten, partially-cooked, and so on). Close the container. Write 'DO NOT EAT' on the container.
  - Keep any unopened containers of similar product, but do not open them.
  - Keep the food away from your regular food supply and away from your family.
- Notify authorities or the retailer:
  - If there is an injury, call the police or regulatory authorities right away to report the incident.
  - Call the retailer.
- Keep information:
  - Keep the container, packaging, label, receipt, and grocery bag that came with the food.
  - Write down any information you remember about the product, such as product codes, 'best before' dates, and where and when product was purchased.

place, which are designed specifically to reduce the risk of tampering within the production environment. Readers are referred to useful 'checklist' documents produced by the US FDA, which deal with prevention.

Manufacturers will have systems in place adhering to hazard analysis critical control point guidelines, which will assist in managing these issues. Automated weight and visual surveillance systems will often detect foreign body issues and reject products, making tamper with some items easy to rule out as a factory issue. Retailers and manufacturers also need to be able to give detailed information on the scope and distribution chain of products to aid the regulatory authorities in their risk assessments.

However, no amount of planning and preparation can remove the tamper risk entirely, and should the unthinkable happen, the crisis management plan should direct staff through the appropriate steps to at least lessen the impact of the incident.

Investigating the Incident

From the perspective of a laboratory that routinely investigates cases of food contamination, the immediate investigation of each and every incident is the crucial first step in deciding how to react. It is worth remembering that when a customer first reports that they have found something in their food, or noticed a tear in their tamper-evident packaging, it need not be the case that tampering has occurred. There is a myriad of other potential explanations, possibly relating to problems in the factory or supply chain, which the food manufacturer and their suppliers may need to address as a matter of urgency.

Similarly, when the extortion letter arrives, but there have been no complaints from consumers or retailers, it is by no means clear that the tampering has taken place, or ever will.

In either event, it is important to gather as much information as possible, and as soon as possible, so that better decisions can be made. There are many things that need to be done beyond a laboratory investigation of course, not least of which will be to involve the relevant authorities in the country where tampering has occurred or been threatened. Most of what happens thereafter will be determined by the police and relevant food authorities, but as noted above, when a case of contamination is first reported, it may be by no means clear that it is due to tamper. At that point, the food manufacturer is in charge of its own investigation.

There are, of course, limits to what laboratory analysis can tell you. Sadly, a real laboratory has none of the magic boxes that are prevalent in television dramas and films. However, as the following intends to demonstrate, the sophistication of modern scientific instrumentation does make it possible to glean far more information than many people realize, and at the very least, this may provide useful corroborating evidence should there ever be an arrest and trial of the tamperer. At best, it may even provide evidence that leads to the arrest.

Foreign Bodies

Foreign bodies might seem to be an obvious 'weapon of choice' for a tamperer. Almost anything will do. It requires no particular expertise to break a bottle to obtain fragments of glass, pick up a handful of nails, or find a dead fly.

It is however, much more complicated to put any such items into a product in such a way that it appears undisturbed, so that some other person will buy it and suffer some consequential damage.

Complicated should not be taken to imply impossible, as much depends on the type of packaging, the nature of the foreign body and the ingenuity of the tamperer. However, it should perhaps persuade a food manufacturer always to question the validity of a consumer complaint that "someone has put glass in the product I bought." It is always easier for a consumer to contaminate the product in this way themselves than it is for an extortionist to do so.

It is for the food manufacturer to decide how best to respond to the foreign body complaint, so it is worth knowing the kind of information that laboratory analysis can reveal.

The first thing to note about any foreign body (never mind the customer's account of how it was found) is that it may not be as obvious as it appears at first sight. For example, there are naturally occurring ingredients that have the appearance of glass, detritus from factory equipment that can look like rodent fecal matter, and ingredient reactions that result in strange precipitates and color changes.

So, no foreign body should be dismissed or accepted without some investigation. For the most part, that investigation will begin with close examination of the foreign body by stereo or compound light microscopy. The techniques used are generally nondestructive and are applicable to very small samples.

In some cases, microscopy will be sufficient on its own to identify the contaminant. In others, the results of microscopy will suggest the most appropriate course for subsequent chemical or microbiological analysis to take. The most commonly encountered foreign bodies and techniques for their analysis are outlined below.

Glass Fragments

Microscopy of any original surfaces of a glass fragment can provide important information on its mode of manufacture, whether, for example, the original glass article was molded (e.g., milk bottle) or spun (e.g., light bulb). Surface interferometry gives information on the curvature of a fragment, distinguishing between flat (e.g., window) and curved glass (e.g., tumbler and milk bottle). Using this technique it is possible to estimate the radius of curvature of a minute glass fragment and thus form a conclusion about the diameter of the region of the item from which it originated.

More information is available from X-ray microanalysis, a technique used in conjunction with scanning electron microscopy. This technique relies on the fact that different elements emit X-rays of characteristic energies and wavelengths when irradiated with an electron beam. Detection of the emitted X-rays reveals the elemental composition of the glass fragment and allows it to be compared with reference samples, either from the factory or from the laboratory database that can have more than 400 samples. Using this technique, it is possible to differentiate between sheet glass,

lighting glass, containers (bottles and jars), lead glass, borosilicate (i.e., heat resistant glass), and domestic glass (tumblers, dishes etc.).

Of course, knowing that a glass fragment came from sheet glass rather than bottle glass, may not be that helpful in deciding whether one is dealing with a case of tampering or not. However, suppose a consumer claims that their fragment relates to a known case in the public domain, but their glass fragments can be clearly shown to be of different origin from those known to be from a tampering incident. This might at least cast doubt on the validity of the claim, and help the understanding of the extent of the problem.

Metal

Like glass, metal fragments and objects may arise from a variety of sources other than tamper, such as factory machinery, packaging (laminated foil), and even dental fillings. Most factories have metal detection facilities online, which helps limit the problem of metal fragments reaching the consumer but none of this equipment guarantees an end to the issue.

The origin of a tiny metal fragment or dust can only be determined once its elemental composition is known. This may be achieved by X-ray microanalysis, which allows distinctions to be made between different base metals, steels, and other alloys. The same analysis can be used to determine any match between samples and reference materials.

In the case of deliberate tamper, one might expect to see whole objects rather than metal dust, especially items that are sharp or rusty.

Plastics

Polymers and plastics have replaced metals and glass in many industrial applications. As a result, plastics present an increasingly common foreign body problem. It is probably fair to suggest that plastics are less likely to be used in tamper cases than glass or metal, because they are generally softer and less likely to cause damage. Few criminals would be likely to choose plastic if they have the option of glass or metal.

However, for completeness, it is noted that a combination of microscopy and spectroscopy techniques can be used to identify plastic materials. Fourier Transform Infrared (FT-IR) spectroscopy or microspectroscopy can be used to characterize the chemical structure of the sample. The spectrum obtained by FT-IR can be compared with reference spectra from a polymer library. A second technique, known as differential scanning calorimetry can also be used to characterize plastics in terms of their melting point, degree of crystallinity, and glass transition temperature. In some cases this will differentiate between different forms of the same polymer.

X-ray microfluorescence spectrometry is another powerful technique for elemental analysis of all kinds of solid fragments and is especially valuable in the analysis of coatings, paint flakes etc. The technique is nondestructive and permits fast, simultaneous, multielement detection for all elements in increasing atomic number from sodium to uranium. It also permits the gathering of qualitative, quantitative, and spatial distribution information. Again, such information can be especially useful in matching samples from different incidents, and forming a chain of evidence that links one incident to another.

Other Foreign Bodies

There are many other potential foreign bodies that the criminally minded consumer might use, especially to contaminate their own product. These include items such as hairs and fibers, insect parts, and animal droppings, all of which can be investigated using a combination of microscopy, microbiology, and chemistry techniques.

It is usually possible to determine the species or family of insect, giving a good clue as to its country of origin and association with specific raw materials. This may help in assessing whether it is likely that the insect arrived in the product through natural means or whether it has been placed there by the consumer. It is sometimes possible, in addition, to use a test to determine the activity of the phosphatase enzyme to verify whether the insect has been heat treated or whether it gained access to the product after processing had finished. This is because the enzyme is heat sensitive and loses its activity on heating.

DNA and protein methods may be applied to animal body parts and to fecal matter to suggest species of origin, or to discount animals entirely. Black bits that resemble rodent droppings often turn out to be balls of congealed fat, either burnt and/or colored by oil and metal dust.

Chemicals

There are thousands of chemicals that might be used for tampering food and drink products, ranging from the obvious rat poisons and strong bleaches legally on sale to the general public, to the narcotics and recreational drugs that require a little more effort to obtain. Then there is the multitude of industrial chemicals that only certain people might have access to, as well as the potions that a handful of committed criminals have been known to concoct in their own homes.

The issue of analysis is therefore hugely difficult to address in a general article. Any analytical approach depends very much on the nature of the product that has been contaminated, the first best guess as to which chemical has been used, and whether known methods exist for extracting and identifying the suspected contaminant. Sometimes methods have to be developed 'on the hoof,' presenting particular challenges to the chemist involved.

Clearly, the sophistication and sensitivity of modern techniques such as gas chromatography–mass spectrometry (MS), liquid chromatography–MS, inductively coupled plasma–MS, nuclear magnetic resonance, and atomic absorption spectroscopy do give the chemist every chance of isolating and identifying any contaminant. Nonetheless, a successful conclusion does largely rely on the expertise and experience of the individual analyst, simply because a food matrix generally contains thousands of other chemical entities that have the potential to interfere with the analysis and obscure any results.

Also, from the chemist's perspective there is a big difference between cases that present like the Tylenol and baby food incidents mentioned. In the former, the tamperer used a strong poison, at levels that were undetectable to the unfortunate consumers. In the latter case, the caustic soda used was so strong smelling that it caused the consumer to cry, and of course, the drawing pins and extortion note were obvious added signs that all was not well!

Any given tampering incident might present to the laboratory at any point on a scale between these two examples. Where no other indication exists, the best one might hope for is that the product smells, looks, or tastes sufficiently strange that the purchaser is persuaded to consume no more before reporting the problem to the manufacturer.

In the subsequent analysis, it is these early sensory signals, often refined and defined by a trained sensory analyst, that give the chemist the best start in identifying the nature of the contamination.

Of course, not every chemical contamination results in a bad smell or taste, and tampering incidents involving chemicals of this kind will only come to light when a consumer is harmed, or the extortion note arrives. Indeed, it may be the case that only the extortion note arrives without any tampering taking place. After all, it is far easier to threaten to poison a product than to actually go out and do it. When the criminal is only interested in easy money, why go to the trouble of working out the best way to tamper with a product and run the risk of a shop's closed circuit television filming the moment that he returns it to the shelf?

That is not a flippant observation. Our laboratory has worked on many projects where a food manufacturer wishes to know if a threat is feasible in practice or too ridiculous to take seriously. By recreating the intended threat it can quickly become apparent if the chemicals to be used are likely to destroy the packaging or product to such an extent that no consumer is at risk of buying it, or perhaps that the chemicals to be used represent no serious threat to anyone's health at the quantities at which it is practically possible to add them.

It is not only the practicality or danger of the chemical that can be assessed but also the vulnerability of the packaging. Obvious questions to ask in such assessments are whether it will be clear to consumers that the product has been tampered with (i.e., effectiveness of tamper-evident packaging). There are many well-designed tamper-evident seals that can be bypassed quite easily by hyperdermic syringe, for example, or packets that are tricky to open from the top, yet surprisingly vulnerable at the bottom.

The vulnerability of packaging leads back to the application of microscopy techniques, because close visual assessment is often required to examine if and how packaging has been compromised by the tamperer. It is often possible to tell, for example, whether a packet has been cut or torn, whether a puncture hole is from a needle or some other implement.

Integrity of Evidence

For any investigation of suspected tampering, or indeed, any other issue of product contamination, it is important that the integrity of the food product and packaging are preserved as much as possible before these items reach the laboratory. No one would want any additional contamination to occur, or any existing contamination to be lost during transit between consumer and analyst. Similarly, it is important that the laboratory retains such evidence as securely as possible in case it is requested by a police forensic laboratory.

Conclusion

Although the food industry must take every possible step to minimize the risk of tamper, through use of tamper-evident/resistant packaging, and by preventing unauthorized access to production facilities, it is clearly the case that tamper cannot be completely prevented. The only 100% tamper proof packaging would also be impossible to open.

It is also clear that tamper is neither the most common crime nor indeed the issue that poses the greatest risk to a food company. There are many other issues that are more likely to compromise the safety of a food product and damage the reputation of the manufacturer. Tamper can occur throughout the supply chain, and the increasing complexity of this chain could impair investigations if tamper occurs at an early point. However, most tamper events occur during retail or the latter stages of the supply chain and are rarely undertaken by organized criminals.

Tampering is therefore one of those issues that must be taken seriously, and that must be considered in any risk management program and in any crisis management plan, but with any luck, it will also be one of those issues that the majority of food companies will never actually encounter.

FOOD SAFETY ASSURANCE SYSTEMS

Essentials of Crisis Management

Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland

Glossary

Crisis A predicted or unpredicted event which represents an immediate or future significant threat to an organization, its employees, consumers, and the public at large.

Focus group A form of qualitative research in which a group of people are asked about their perceptions, opinions, beliefs, and attitudes towards a product, service, concept, advertisement, idea, or packaging.

Food industry The term includes primary, manufacturing, and processing industry as well as some other establishments involved in the food chain.

Food safety Assurance that food will not cause harm to the consumer, when it is prepared and/or eaten according to its intended use.

Management commitment Direct participation by the highest level executives in a specific and critically important aspect or program of an organization. In quality management it includes (1) setting up and supervising or serving on a quality committee, (2) formulating and establishing quality policies and objectives, (3) providing necessary resources and training, (4) overseeing implementation at all levels of the organization, (5) evaluating and revising the policy in light of results achieved, and (6) ensuring that internal or external complaints, in particular reports by whistleblowers are thoroughly examined and adequately addressed.

Risk communication The interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Traceability The ability to follow, forward as well as backward, the movement of a food through specified stage(s) of production, processing and distribution.

Whistleblower A person who tells the public or someone in authority about alleged dishonest or illegal activities (misconduct) occurring in a government department or private company or organization.

Introduction

In any organization dealing with a risk-prone subject such as food, chemicals, drugs, health, transport, finance, a crisis is an almost unavoidable situation; any organization with a professional management should be prepared for it. Organizations operating in the food sector, be they a food business or agencies responsible for overseeing food businesses, are by nature of their work exposed to such an eventuality.

The vulnerability of the food sector to experiencing a food crisis comes from the fact that over and above human errors there may be other totally unexpected event or finding (the Black Swan Effect) such as the emergence of a new biological or chemical agent. This was the case with epidemic of cholera in Latin America in early 1990s, bovine spongiform encephalopathy (BSE) in UK (1996), acrylamide (2002), semicarbazide (2003).

Factors that can trigger a crisis situation are summarized in Table 1.

It is to be stated that what is or not a crisis depends also on the reaction of the public, industry, and governments, but it also depends on the geographic location where the event takes place and the perception of risk, culture, and societal values. There may be issues that would generate a crisis in North America and not in Europe or vice versa. For instance, the information on health risk associated with acrylamide did not cause the same reaction in North America than in Europe.

The consequences of a crisis can be disastrous for an organization as well as for the society. For consumers, a food safety crisis situation means that they may potentially be exposed to unsafe products and lose their trust in the food supply. For businesses, consequences are economic and affect their image, i.e., product recall and waste of produced food; loss of reputation; loss of market shares; and loss of the trust of consumers, customers and regulatory authorities. Additionally, they may be subject to further or more stringent regulatory measures. Loss of trust by customers may also trigger more stringent requirements, for example, provision of a certificate of analysis. Trust of consumers, customers is one of the most important assets of a business or an organization. It takes many years to build trust, but it can be destroyed with one single incident, particularly if it is poorly managed. When lost, its impact is often long-term and will take many years to rebuild.

For public health and regulatory authorities, even when a crisis is initiated in the industry, the good management of a

 doi:10.1016/B978-0-12-378612-8.00371-1

Table 1 Factors that trigger a crisis

Triggered by	*Examples of crises*
New scientific findings	• Acrylamide (Worldwide, 2002) • Semicarbazide (Worldwide, 2003)
Emergence of new hazards	• Bovine spongiform encephalopathy (Worldwide, since 1986) • *Escherichia coli* O157 (US, Japan, Europe, etc. since 1980s) • *Vibrio cholerae* (Latin America, 1993) • Avian influenza (2004)
Human error: Scientific, technical, managerial Operational error, or violation	• *Salmonella* in chocolate (UK, 2006) • Vitamin B1-deficient infant formula, ex-Germany, Israel 2003 • Isopropylthioxantone (Worldwide, 2005) • *Salmonella* Saintpaul (US, 2008) • *Salmonella* Typhimurium (US, 2008–09) • *E. coli* O104:H4 (Germany, 2011)
Fraud or malicious acts of sabotage, for example, tampering, terrorism	• Dioxin in animal feed (Belgium, 1999) • Wheat gluten in pet food adulterated with melamine, ex-China (North America, 2007) • Adulterated sunflower oil ex-Ukraine (Europe, 2008) • Infant formula adulterated with melamine (China, 2008) • Beef adulterated with horse and pork meat (Europe, 2013)

crisis is crucial, because consumers consider their government as the guardian of the safety of the food supply and as ultimately responsible for food safety.

Where governments fail to manage a food safety crisis, they may also lose their image, reputation, and the trust of the general public in their capabilities to ensure safety of the food supply. In such a scenario, the trade in food can collapse. Such situations were experienced with meat and meat products in the BSE crisis in the UK and other European countries, and with fruits and vegetables in the case of *Escherichia coli* O104:H4 in Germany. Failures in managing an incident or a crisis have also been the cause of political turmoil. Following the 1999 dioxin crisis in Belgium, the Belgian Ministers of Agriculture and Health had to resign. The ruling Christian Democratic government was also voted out of office. In China, following the melamine crisis, the governmental officer in charge of food safety was executed.

The loss of trust of consumers in their authorities following the BSE crisis and a plethora of small- or large-scale incidents which occurred is one of the factors leading to the mistrust of consumers for new technologies like genetically modified food, food irradiation, and application of agrochemicals in the food productions. In Europe, many consumers turned toward organically produced food.

The consequences of a crisis for an organization or a society depend on how well the organization or the society is prepared for a crisis situation. As for a boat whose survival through a storm depends on its solidity, the training of the sailors and the skills of the captain, the outcome of a crisis depends on the infrastructure in place, the training of the staff, and the management skills of the manager.

From the above, it can be understood that the importance of crisis management, and preparation for it, cannot be overemphasized. Provided that crises:

i. do not occur too frequently,
ii. are not a consequence of obvious or gross negligence,
iii. do not involve unethical or malicious malpractices, and
iv. health and concerns of the general public are given priority.

A good crisis management can to some extent reinforce the trust of consumers and trading partners or improve the reputation of the affected organizations, or at least limit the damage. Consumers who would observe that, in case of any adverse event, the business or the government will take necessary measures to protect them will have increased trust in the business and governments. As mentioned above, in a crisis situation, both governments and the industry may be implicated and will have to bear the consequence of a crisis; therefore, interactive communication and full transparency between the two parties is essential. Additionally, both may be brought to explain why their preventive measures failed.

Whereas collaboration and communication between governments and industry is important to manage a crisis, it is also important that the process of decision and implementation are not biased. Therefore, the principles for risk management and the process of risk analysis developed for the management of food safety in normal times applies also in a crisis situation, except that decisions have to be taken under time constraint, with incomplete data, and often under media scrutiny. The more the food safety management in a country is solid in terms of organization, for example, definition of responsibilities, values, standards (existence of legislation and enforcement mechanism) and procedure, and skilled and competent managers the better the country will be prepared for managing a crisis situation. The same applies in a food business. In the dioxin case in Belgium in 1999, the lack of norms for dioxin at the European level and of traceability were gaps that, among others, negatively impacted the management of the crisis. In a similar dioxin crisis a few years later in Ireland, the existence of a norm was one of the factors that eased the decision making process.

As for food safety management, crisis management requires a structured, systematic, and consistent approach and includes four stages:

1. Crisis prevention.
2. Crisis preparedness.
3. Crisis management.
4. Recovery and rebuilding after a crisis.

The following principles and recommended practices for crisis management are formulated in a general manner. With some adaptation to the circumstances, they can be applied both in governments and in industry.

Crisis Prevention

It has to be recognized that a crisis situation starts when food safety management has failed. Therefore, regardless of how well it is managed, a crisis is often an indication of failures in food safety management and will have some negative consequences, particularly if crises occur too frequently or past errors are repeated.

Management of a crisis situation mobilizes a lot of resources within the organization and disrupts the normal operations. Therefore, the repetition of a crisis situation not only will erode the trust of the trading partners, customers, and the public at large, but also undermine the routine of the operations and will wear out the staff. Subsequently, these may be more disposed to human error. A vicious cycle of vulnerability sets in. Hence the importance of preventive measures, as the better we manage food safety, less likely we are to have a crisis. Thus, paradoxically and ironically, the best crisis management becomes its prevention.

The preventive measures are not any different than those that are necessary for food safety management; crisis management should be seen as a continuum of food safety management. For an overview of food safety management, the reader is referred to the article on food safety management. However, some aspects of food safety management find particular importance during a crisis situation, these are described below.

During a crisis, trust becomes a very important asset, as people operate under acute conditions requiring real time and strategic decisions taken at high level. Owing to the urgency of the situation, there is no time for checking the validity and thoroughness of the data as in a normal situation. Many decisions are to be taken based on the trust in the integrity and competence of staff or experts and on their respect of the values and policies of the organizations. However, trust is not built or achieved in one day; it takes years of good practice and of responsible and transparent behavior and management. Although, as mentioned above, the practices during a crisis management can enhance and reinforce trust, its foundation is to be built during normal periods, i.e., during the day-to-day operations. An organization that behaves responsibly will not have difficulty in transparency and giving the truth about the cause of its incident. Therefore, values such as open organizational culture, transparency, prioritizing the safety of products over economic considerations should be spelled out in the policy of organizations and actively supported by the Management. In other words, policies should not be a declaration of good intentions but practiced by the leaders on a daily basis.

As part of management, the definition of policies, processes, responsibilities, and the provision of logistic support all are important for a good management of food safety. Additionally, in a food business, the food safety assurance system, including good manufacturing practice, the hazard analysis and critical control point system and various verification measures, will need to be implemented in a flawless manner. Regulatory authorities should also monitor the food supply for safety and have an efficient foodborne disease surveillance program to depict any problem at an early stage.

An important and integral part of the food safety management system is management of human resources, as no matter how many principles, systems, and tools are innovated for managing food safety, it is finally the staff who have to implement these. Human resource management is often a neglected area in food safety management, whereas it is fundamental to an efficient food safety management and should be considered at the heart of the system. Experience from various crises shows that very often failures leading to an incident or a crisis are known by the staff, or could have been predicted; however, due to fear for repercussions on their career, they fail to report or do not bother to report as they do not believe in the fair evaluation of their information.

Therefore, over and above their knowledge and skills, staffs need to be motivated and encouraged and most importantly, not fear for their career or potential repercussions when reporting potential gaps or malpractices. Any gap or malpractice which is addressed at an early stage will decrease the risk of an incident and eventually of a crisis. Employees need to believe in the commitment of their Management in the true sense of the word. Hence the importance of credibility of the Management and their walking the talk on a consistent and continuous basis, as any noncompliance or complacency at the higher level of management will set a bad example for the entire organization and have serious repercussions on the entire organization. The importance of management commitment, having an open culture, promoting the reporting of problems, and their investigating and closing the gaps for prevention of crisis cannot be overemphasized. Naturally, governments have the leading role in protecting the right of the staff and whistleblowers.

As part of food safety management, but of particular importance to crisis management, are of course traceability, recall procedure, and the procedure for crisis management itself. The latter will be described below. With regard to traceability, without such a system, in case of a nonconforming ingredient or a product, it will not be possible to make a selective recall of products, and all products suspected to be potentially affected will have to be recalled and destroyed. A case in point is the incident with dioxin in Ireland (1999) where, due to the absence of traceability, all pork products were recalled, whereas for beef, as a traceability system was established following the BSE incident, a selective recall, i.e., a recall of contaminated products, was possible. The same applies for an incident affecting a food business. The finer the traceability system, the more likely it will be possible to narrow the recall of products that are affected by a contaminant. For instance, a company

that can trace a contamination to the precise time of production can limit the recall to those specific products. In absence of such a system, unless the nature of the contamination is such that it is possible to segregate affected products by testing, all the production of a day, week, or longer period may need to be blocked and withdrawn.

Many organizations may also benefit from an active early warning system or may even do research on potential emerging issues. Such a system is at the frontier between prevention and preparedness for crisis management. Depending on the nature and size of the organization, the system could include monitoring, surveillance, and analysis of:

1. literature and scientific data,
2. the regulatory development and alert networks,
3. incidents and experience of other companies and countries,
4. consumer complaints,
5. foodborne diseases, animal diseases, and monitoring of contaminants,
6. postlaunch of new products,
7. audit and/or inspection reports, reports of compliance of products, and
8. internal account of staff reporting noncompliance or mismanagement.

Crisis Preparedness

One of the key principles for crisis management is the speed of action, be it investigation into the case or informing the general public. In all incidents where there has been a delay in action, it has caused outrage and hard judgment by the public. In the dioxin incident in Belgium (1999), melamine in China (2008), *Staphylococcus aureus* in Japan (2000), and *E. coli* O104:H4 in Germany (2011), one of the main failures for which the responsible authorities were severely criticized was the delay in removing products from the market or in informing the public; a similar experience was observed with Toyota (2011) and Sony who were slow to inform the public about their defective cars or their security system that was hacked. Therefore, to ensure a rapid course of action in such a situation, a certain number of actions and activities have to be carried out in advance to actively and specifically prepare for a crisis situation. To this end, it is important to consider:

1. Infrastructure and resources that may be required during a crisis include:
   - Developing a network of collaboration and alliance with various stakeholders, as during a crisis there will be a need for a rapid exchange of information. Examples are media, other food companies or industry associations, regulatory authorities, and consumer organizations.
   - Being aware of the regulatory requirements in relation to: (1) the procedure for reporting an incident (i.e., who should be informed, at which point and what kind of information needs to be provided), (2) legal requirements for withdrawing or recalling products, (3) eventually for disposing of contaminated products in a safe manner, and (4) penalties or penal actions for the responsible person, in case of consumer injuries.
   - Being informed of the requirements of the Codex Alimentarius Commission and the International Health Regulation in case an incident or an outbreak takes an international dimension or affects foods entering the international trade.
   - Foreseeing the scientific support (e.g., access to experts) and additional logistic support.
   - Organizing a database on products and their traceability records, i.e., their destination and/or the source of the ingredients.
   - Establishing a contingency plan, for example where the work or operations can be transferred, or how raw material can be sourced (alternative source).
   - Definition of roles and responsibilities in times of crisis and the network of people who should be informed.
   - Additional administrative support and infrastructure, such as designation of a specific meeting room, extra lines for telephone, mobile phones, etc.
   - Good organization (responsibilities, network) and written procedure, for example, first minute actions.
   - Red folder: Data needed in case of accidents: organization chart, emergency telephone numbers, phone numbers of key partners, governmental agencies, food companies, customers, scientific experts, and specialized laboratories.
2. Principles and procedures. As for defining procedures and principles, it is important to also define the specific procedures for crisis management, i.e., how the early warning system should work, who decides, implements, and communicates during a crisis situation. Often these may be the same as in normal circumstances; however, each organization has to give this matter specific consideration and take a conscious decision, as the same infrastructure and setup may not be suitable for all types of conditions and organizations. The types of questions that should be considered are:
   - The line of reporting of information.
   - The type of information (consumer complaints, regulatory actions, media, disease surveillance, food ban, etc.) that should be reported as part of early warning.
   - The crisis manager and the skills required for this position.
   - Composition of the core crisis management team, competence needed, and responsibilities.
   - Those who should possibly be informed internally or externally (regulatory authorities, medical community, consumers/general public, suppliers, customers, media, food companies, trade or international organizations, and police in case of tampering).
   - Define the principles of decision making and the authority, i.e., who would need to approve a decision.
   - The person who will be responsible for implementing decisions and for following up.
   - The spokesperson.
   - The procedure for preparation of the communication.
   - How the issue will be coordinated nationally or internationally.
3. Defining a crisis manager. It is to be noted that the crisis manager does not always need to be the same as the food

safety manager. A crisis manager should have specific skills, such as:

- Leadership;
- Good technical knowledge (scientific, product, supply chain, and regulatory information);
- Organizational management skills;
- Public relations and communication skills;
- Recognition and trust of stakeholders;
- Experience;
- Emotional intelligence (empathy); and
- Pragmatism and common sense.

Finally, as part of crisis preparedness, it is important to communicate to all stakeholders, or all potentially involved parties, the flow of reporting, i.e., the communication plan, and the principles and procedures; it is also important to train the crisis team members in crisis management, and periodically perform a crisis management exercise to ensure that the procedures and principles are correctly understood, feasible, and complied with. It is clear that in the light of the outcome of the exercises or in case of any new internal or external experience, the crisis management procedure is to be reviewed and improved. An important element for training is, of course, skills in crisis communication. As will be seen in section Crisis Communication for this purpose, specific skills are required.

Crisis Management

Then comes the time when the house is on fire, i.e., a crisis hits. The procedure, for example, convening the crisis management team, informing the management, is to be put in place. It is important to act swiftly, but calmly. Speedy and timely decisions and actions are key, but it is equally important not to take decisions in a panic mode, and as far as possible to take the decisions in consultation with the crisis management team, and/or depending on the case, with the support of the management of the organization. Where applicable, external bodies, for example, other industries, or industry associations, or government of other countries or international organizations, may need to be consulted.

In the eye of the storm, a number of decisions are to be taken and implemented. To this end, a few principles are to be observed:

1. To get the facts right and be aware of uncertainties. Examples of information which would be required are:
   - What has happened?
   - What level of contaminants was found in the food, which method was used and its validity, sensitivity of the method, possible product variation or limitation of the analytical techniques, or the competence of the laboratory.
   - Range of products that are affected, the time the affected products have been on the market, i.e., how far back a product may need to be recalled if necessary, their expiry date, their distribution, and products which are in the warehouse at the time of the crisis.
   - What was the possible cause of the problem? This information will be essential to determine which products, and up to which time, need to be pulled out of the market.
   - Who is informed about the subject?
   - Evaluating risks and possible management options. In evaluating the risks, the health consequences for consumers should be the primary concern and the priority. As part of this, different types of risks need to be considered, for example, safety risks versus nutritional risks. Safety risks can also entail microbial versus chemical risks. It is to be borne in mind that a rapid change in a product or food consumption pattern without taking the necessary precautions may also lead to exposing consumers to new risks. Other types of factors to consider in the decision making process are regulatory and legal aspects, potential environmental risks, reputation risk, economic and financial implications, social consequences, perception issues. Decisions are to be taken based on the above consideration and considering the pros and cons of different management options, including feasibility and possible time frame.

To ensure that the intentions with decisions are understood and the decisions are followed, it is important to explain the basis for decisions and to keep records on the reason for the decisions, those who participated in the decision making process, as well as the data that were considered. The implementation and the outcome of the actions are to be monitored and evaluated at all times. Where necessary, for example, in the light of new information, the course of action or decisions may require amendments. In taking decisions, it is important to consider both short-term as well as long-term consequences, and also to think globally as today food safety is global and decisions can have broad consequences. Experience in other countries may also be beneficial. Finally, to ensure a rapid course of action, it is important to have a plan of action (including a contingency plan).

Crisis Communication

During the last two to three decades, there has been an increasing recognition of the importance of risk perception and risk communication, in particular during the period of a crisis. It has, among others, been realized that perception of the general public, although not always based on science or in line with the view of scientists, is the main driver in the acceptance of products and/or technologies and influences the food market. A huge amount of research has been carried out in recent years. It has been found that the perception of consumers is influenced by a number of factors such as:

1. Prospects of significant benefit for 'me'.
2. Whether the risk is voluntary (consent) or involuntary.
3. Whether the risk is familiar.
4. The 'dread' factor in the risk.
5. Whether the risk and benefit are 'fairly' distributed.
6. Whether the risk is part of an unethical activity.
7. Whether the risk assessor and risk manager are trustworthy.
8. Whether the risk is natural or unnatural.

Consideration of these factors is important, as much in the risk communication as in the decision making. For instance, in an incident where infant formula was contaminated with traces of photoinitiator in ink in 2005, the affected food

companies decided not to recall their products on the grounds that the contamination did not represent a risk to health, whereas many consumers would not accept to buy such a product and as the risk was unnatural, involuntary, and the risk benefit was not equally distributed. With regard to risk assessment and risk communication, the fact that initially, the risk assessment was carried out by the infant formula manufacturers and not by the authorities undermined the validity of risk assessment and communication. However, in an incident which occurred two years earlier in 2003, where traces of semicarbazide were found in baby food, the rapid risk assessment by the European Food Safety Authority and its communication to the general public led to a more peaceful resolution of the crisis.

Consumers and interested parties get their information in different ways. Therefore, different methods and means of communication need to be used to reach the target audience as widely as possible. These include: press release and/press conference, TV interview, website, podcast, telephone voice messages and hotline for specific consumer queries, alert networks such as the European Rapid Alert system, the World Health Organization/Food and Agriculture Organization of the United Nations, International Food Safety Authorities Network (INFOSAN), etc. A rumor hotline can also help the crisis management team understand if any erroneous message needing correction or explanation is circulating.

Experience from a few crises shows that in the heat of the management of a crisis, a few groups of people are forgotten in the line of communication; they are mentioned here as *aide-mémoire*, as depending on situation, it is essential to keep them informed. Some may need assistance with a brief, a draft declaration, or a Question and Answer, in case they are contacted by the public or the media. These are:

1. the Chief Executive Officer or the Director General of the organization;
2. trade associations/regulatory authorities, or international organizations;
3. stakeholders of the food chain, for example, retailers;
4. employees; and
5. the switchboard or consumer services on possible answers to the general public or consumers.

The exact choice of the method and the mechanisms of communication depends on the case, and the strategy for communication needs to be examined very carefully so as not to create undue panic in the population, yet to inform them as needed. In the 2002 acrylamide crisis, the Swedish authorities decided to hold a press conference. According to communication experts, this method of communication created a big communication crisis and media attention, although contaminant was not new (humans have been exposed to it as far back as the Paleolithic period when food was cooked over fire), its risk were not yet known, and its content in the food could be reduced only after extensive research, meaning that an alarming communication would only create panic without providing consumers with a solution.

A few additional principles need to be considered in crisis communication:

1. Speed: A communication should be made within 24 h.
2. Accepting blame for death or injury, if the product is proven to be implicated, even if the cause is still unclear.
3. Coordinate all communications through one person.
4. Depending on the situation, the communication could include: the facts, i.e., what is known and what is not known, the decisions, actions, and the basis for the decisions.
5. Communicate in such a way as to avoid any misunderstanding by the audience, i.e., the potential for being understood in different ways than what was meant. This can be done by testing the communication on a focus group or people representing the target audience.
6. Confirmation of receipt of important messages.
7. Full transparency and consistency, in particular to be aware that any attempt to downplay or hide facts will cause more damage to the reputation.
8. Having and expressing empathy with the victims and affected people.
9. Frequency, mode, and content should be culture-specific and effective for the specific target consumers.
10. Avoiding terms that would amplify the scare or unduly minimize and mislead the target audience.
11. In communicating with the media, any gap in information can lead to misinformation.

Documentation and Records

Documentation and records are important means of communication and these are an equally important task in the management of food safety.

In a crisis, which is often a situation where the safety of products have gone out of control, having records of events, decisions, and actions, as well as supporting documentation becomes even more important. As part of this, all facts and decisions are to be recorded in a logbook. The logbook should contain records of the events, who decided what and who was informed. When meetings have taken place, it should also include minutes of the meetings. These should also record reservations made by any member of the crisis management team and should also be disseminated to all attendees and other interested parties. The preparation of a case report on the event can help in communicating the event to stakeholders in a consistent and transparent manner, and also facilitate the identification of any discrepancy and/or uncertainty that may be detrimental to the process of decision making. It can also support the development of consensus and the later evaluation of decisions and of the crisis management.

Another important document is a statement or the position of the organization for communication to stakeholders (authorities, industry, media, public, or internationally).

Recovery and Rebuilding after a Crisis

Management of a crisis is often so exhausting that once the storm is over, members of the crisis team tend to return to their normal duties. However, the evaluation of the crisis management and determination of the root cause of the incident, its consequences, lessons learned, and corrective

Table 2 Summary of lessons learned from various incidents and crises

Incidents	*Lessons learned*
S. aureus intoxication, milk (Japan, 1955)	• Importance of rapid action (halt of sale, recall of products, and public apology) increases trust
Mineral water contaminated with benzene (France, 1989)	• Rapid product recall increases trust • Importance of valid information for decision-making • Attempts to downplay the extent of an incident will damage the reputation of a company • Importance of consistent communication • Importance of international coordination
BSE/vCJD (Worldwide, (Europe, 1996–2000))	• Importance of transparency and ability to communicate uncertainty to public • Importance of prioritizing public health over economic considerations • Importance of consumer/public perception (e.g. dreadful nature of disease) • Need for separation of risk management from risk assessment • The social dimension of food safety • Importance of traceability and farm-to-fork approach • Role of media • Importance of risk communication by a global public health authority
Animal feed contaminated with dioxin (Belgium, 1999)	• Importance of speed of action • Demonstration of the complexity of the food chain and the need for traceability • The need for farm-to-fork approach • Role of media • Importance of risk perception • The need for resources (e.g. laboratories)
Soft drink allegedly contaminated with pesticides (Belgium, France, 1999)	• Importance of communication • Importance of considering the context of an incident • Voluntary recall can increase trust • Role of media
S. aureus intoxication, milk powder (Japan, 2000)	• Speed of action • Priority to public health • Communication: empathy with the victims • Full transparency: any attempt of denial, or minimizing the impact (false or partial information, partial product recall) will damage the reputation more • Preparation: clear procedures and training • Mechanism for reporting problems to management • Beware of culture of fear!
Mislabeling of beef product (Japan, 2001)	• A good crisis management does not always help! • Fraud and ethical malpractice will not be forgiven
Packaging contaminant: semicarbazide (Worldwide, 2003)	• Early and transparent communication of the food industry increases trust • A rapid risk assessment and communication by trusted sources prevent escalation of a crisis and ensure coherent actions across Europe
Packaging contaminant: isopropylthioxanthone, (Worldwide, 2005)	• Importance of risk assessment and communication by competent authorities • Alignment with government views • Coordination of government agencies • Importance of risk perception • Financial consequences can also create a crisis • Importance of documentation and records • Media plays an immense role
Salmonella/peanut butter (USA, 2006 and 2008/9)	• Importance of root cause, corrective actions based on understanding the underlying factors for malpractices
Pet food adulterated with melamine (North America, 2007)	• The need for additional resources (e.g. to handle consumer queries) • Early reporting to public health authorities to minimize damage • Importance of coordination and communication between authorities • Importance of considering the fate of disposed products • Root cause analysis of incidents and dissemination of our experience can prevent future crises
Sunflower oil adulterated with mineral oil (Europe, 2008)	• International coordination to prevent dumping of contaminated food to other countries or food sectors • Difference between being allowed to keep a contaminated product already in the market and being allowed to release that product
Melamine/infant formula (China, 2008)	• Importance of root cause, corrective actions based on understanding the underlying factors for malpractices • Risks associated with fear culture • Control of contaminated products and their safe disposal
Enterohemorraghic *E. coli* (EHEC O104:H4) and fenugreek (Germany, 2011)	• Importance of speedy action • Validation of information before communication to the general public

(*Continued*)

Table 2 Continued

Incidents	*Lessons learned*
Horsemeat (Europe, 2013)	● Coordination among authorities ● Impact of public fear on food market ● Lack of ethics in food businesses ● Complexity of the food chain, limitation of traceability ● Where there is no ethic, all kind of unpredictable problems can happen

Abbreviations: BSE, Bovine spongiform encephalopathy; vCJD, variant Creutzfeldt–Jakob disease.

actions are very important for preventing future incidents. In a case when an infant had died (Belgium, 2001) where the contamination of infant formula with *Cronobacter sakazakii* (previously *Enterobacter sakazakii*) was considered as a possible cause of the incident, the authorities questioned the manufacture on the corrective actions that the company had taken since its previous *C. sakazakii* incident. Thus, the outcome of the evaluation can be instrumental in improving the crisis preparedness and procedures, or the food safety management system in order to prevent or minimize future problems. A final report on the case, including the root cause analysis and the lessons learned, needs to be communicated widely to prevent future similar cases. Lessons learned from some of the major food safety crises are presented in Table 2 as examples. Public health authorities need to also report the results of their investigations. The repetition of several important incidents, for example, melamine, salmonella in chocolate, salmonella in peanut butter, tends to indicate that the causes of incidents are not always fully investigated and the lessons learned are not widely communicated. Finally, the roles and responsibilities, including those of the members of the management, in the incidents need to be clarified. A major mistake would be to fire the personnel who *a priori* is viewed as responsible before the investigation is finalized and the root cause of the incident is identified. A critical review of the root cause of incidents can show that not infrequently, the failures can be traced to the management's practices and commitment.

Conclusion

In life, the unthinkable can happen. In food safety, every detail may be the occasion for an incident or mishap with the potential for causing a crisis. A proactive approach to the management of food safety can minimize the likelihood of an adverse event leading to a crisis. A crisis is never good and will cause damage; it should by all means be prevented; however, when it occurs, how it is managed can be the opportunity for demonstrating the management capabilities and the values of an organization. In the management of a crisis, the objectives should be to maintain the trust of the stakeholders, in particular the public, authorities, and trading partners. Decisions should be based on facts, including consideration of the uncertainties, and putting the health of consumers as a priority. The perception of consumers is also an important consideration. Speed of action, a consistent and transparent approach, and empathy for the victims are some of the key values for which an organization would be scrutinized. In a crisis situation, the media plays an important role and the communication with the media, or through the media with the public, is key for the management of a crisis. The values and the culture that an organization promotes and actively implements is a determining factor for the early identification and management of potential issues and for the prevention of a crisis.

Root Cause Analysis of Incidents

Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland
CA Wallace, University of Central Lancashire, Preston, UK

Glossary

5-Whys A problem-solving technique for identifying the root cause of a problem.
Failure mode and effect analysis A problem solving method for investigating possible causes and effects of failures in systems.
Hazard and operability study (HAZOP) A structured, systematic technique for examining potential faults in system.
Incident A deviation from standard practice leading to sub-standard product or dissatisfaction of customers/consumers or regulatory authorities, for example, due to injury or perceived food safety problems.
Influence diagram A pictorial method for portraying the causal factors in an incident happening at different levels within an organization.
Ishikawa cause and effect analysis A pictorial method for grouping information and understanding the relationships between cause and effect.
Root cause analysis A method for tracking back to the root or originating causes of an incident or problem.

Introduction

One of the fundamental expectations of consumers is to be able to trust the safety of food supply. This means that consumers should

1. be able to rely on food businesses and a responsible management of the safety of their products and
2. be confident that regulatory authorities are competent to oversee the safety of the food supply, in particular, the operation of food businesses.

It is also recognized that in spite of all efforts, incidents – be they due to human error or other reasons – may occur and substandard products may reach the market. Experience has shown that although consumers and the general public may tolerate incidents, they will not accept repetitive incidents resulting from negligence or complacency, or deliberate violation of the law. Therefore, in the case of a failure, a responsible management must not only take immediate corrective action but also ensure that the failure does not reoccur. To this end, in the case of any incident, or a near-miss situation, a root cause analysis of the causes of the failures needs to be carried out.

A root cause analysis should not be mistaken with the investigation of the primary cause of an incident, which must be carried out as part of the management of an incident. Rather, a root cause analysis is a postmortem exercise for better understanding the underlying factors leading to an incident or a near-miss situation.

Concept of Root Cause Analysis

To understand the concept of root cause analysis, examining the way an incident occurs is important. This has been described by James Reason, and his approach to organizational incidents is used here.

In food safety assurance, a series of measures are foreseen to control hazards. These measures can be grouped under basic good practices, hazard analysis and critical control point (HACCP), and verification measures. When an incident occurs, usually it is the result of a gap or failure, or rather a series of gaps or failures, in these measures. A gap or failure in any of these measures creates a weakness or vulnerability in the food safety management system and causes the threat situation, which, if investigated and corrected immediately, prevents an incident from occurring or recurring. However, if a gap is not addressed, with time, combined with some other gaps, it may potentially lead to an incident, and if this incident is not managed effectively, it may escalate to a crisis situation. Such situations where gaps of different level and nature can combine to cause an incident are referred to as the 'Swiss cheese model' (Figure 1). An example of the additive effect of gaps in systems is the crisis where chloramphenicol was found in honey imported from China. In 2002, honey, or products containing honey, manufactured by a large number of food companies were contaminated with the illegal antibiotic chloramphenicol. A root cause analysis of the incident showed that at that time China did not have legislation against the use of chloramphenicol, and the food manufacturers in Europe were importing honey without verifying the product for chloramphenicol. The situation led to a major crisis in Europe, with loss of millions of euros (Figure 2(a)). In another incident in Israel in 2003, some 15 babies suffered from damage to the nervous system and 2 died. The incident was due to infant formula that was deficient in vitamin B1 (thiamine). In this incident, the cause of the incident was an error in product formulation, but a second failure was in the

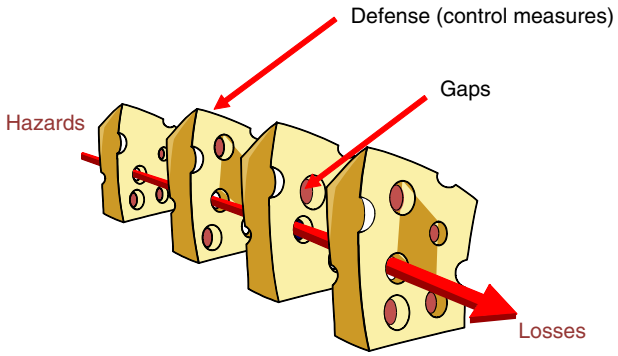

Figure 1 Swiss cheese model. Reproduced from Reason JT (1997) *Managing the Risks of Organizational Accidents*. Aldershot, UK: Ashgate.

verification of the composition of the product before its release (Figure 2(b)).

A second concept that must be understood is active and latent failures relating to management of people (Figure 3). Behind any control measure, there are people who have to implement the measures or verify that they are correctly implemented. These can, for instance, be a worker on the line or in the farm, an operator monitoring the temperature recorder, a truck driver who has to manage the temperature during transportation, a food handler who has to wash his hands before preparing food, etc. Failures to perform these tasks are referred to as active failures because their actions will have a direct and immediate bearing on the safety of products (Figure 3). These are the types of failures that are typically investigated in case of an incident or near misses. Often, as a result of the investigation, an employee is blamed, or may even be fired. Usually the investigation ends at this point. The same process and relationship also exist between regulatory authorities and food establishments that are implicated in an incident.

However, in a root cause analysis the task is to go deeper in the investigation and understand the conditions that have led to the noncompliance, i.e., understanding the reason for the implicated person to commit the so-called active failure. Worldwide, studies indicate that factors that lead to active failures are often related to the working conditions, for example, time constraint, lack of clear instructions, failure in defining the responsibility or authority of the person or in providing adequate training and coaching, creating a culture of fear or demonization, etc. Such situations are latent conditions that result from management decisions and management culture. Failures of the management in creating conditions that are optimal for managing food safety are referred to as latent failures (Figures 2(a), (b), and 3). Latent failures may not have an immediate impact, but they weaken the food safety management system and increase its vulnerability. They create opportunities for active failures and incidents. Latent failures have been the cause of numerous accidents in the petrochemical, transport, and food industries and in financial institutions.

To recapitulate, a root cause analysis requires a truthful and objective investigation of an incident at several levels, i.e., understanding

1. the primary cause of the incident: often a technical mistake, equipment failure, or human error/violation. Examples are errors in the technical parameters of a product or processing, a broken sieve, or a staff using a wrong thermocouple;
2. the conditions leading to the noncompliance of the person in charge of implementing the control measures, such as lack of training, time constraint, or difficulty to understand an instruction; and
3. the managerial decisions that have led to those working conditions, for example, failing to provide the necessary policies, to appoint a competent manager or personnel, to plan an optimum reporting and organizational structure, or to provide adequate financial or human resources, or adequate equipment, and a management behavior in contradiction, or in violation, with the instructions, or requiring impossible tasks and forcing staff to take risky shortcuts or violate the rules. Worst would be a management that promotes a fear culture or violates its own policies. This will have repercussions for the entire company.

Therefore, to ensure that root cause analyses are carried out objectively and in-depth, it is important to ensure the independence of investigators. A responsible business will accept the investigation of the root causes of incidents up to the management level, as frequently, but not always, the incident is due to shortcomings at the management level or due to a lack of management commitment.

Tools for Root Cause Analysis

Root cause analysis is used quite widely in healthcare and business settings, but as yet, it has not really been adopted by the food industry to any great extent, although the concept is identified as necessary in some Food Safety and Quality Certification Standards, for example, the BRC Global Standard for Food Safety, Issue 6. However, some of the tools of root cause analysis, notably structured failure mode and effect analysis (FMEA), have been used for some time in food companies for various applications. For example, Mortimore and Wallace advocate the use of FMEA to challenge the controls within an HACCP plan before it is implemented within a food operation, the idea being that by understanding the likely causes of failure in the control systems, the controls can be strengthened further, delivering additional confidence of food safety assurance.

As discussed earlier in this article, root cause analysis needs to investigate an incident in detail to gain an understanding of all the conditions that have led to the incident. It is necessary to consider all possible contributing factors, and this requires both a structured approach and the ability to 'think the unthinkable.'

Root Cause Analysis Teams

Like many aspects of food safety management systems, root cause analysis is best performed using a team approach rather than by an individual or individuals working alone. The team needs to include personnel from within the business who have knowledge of key areas of investigation. These include personnel who have knowledge of and responsibility within technical/quality, manufacturing, and engineering functions

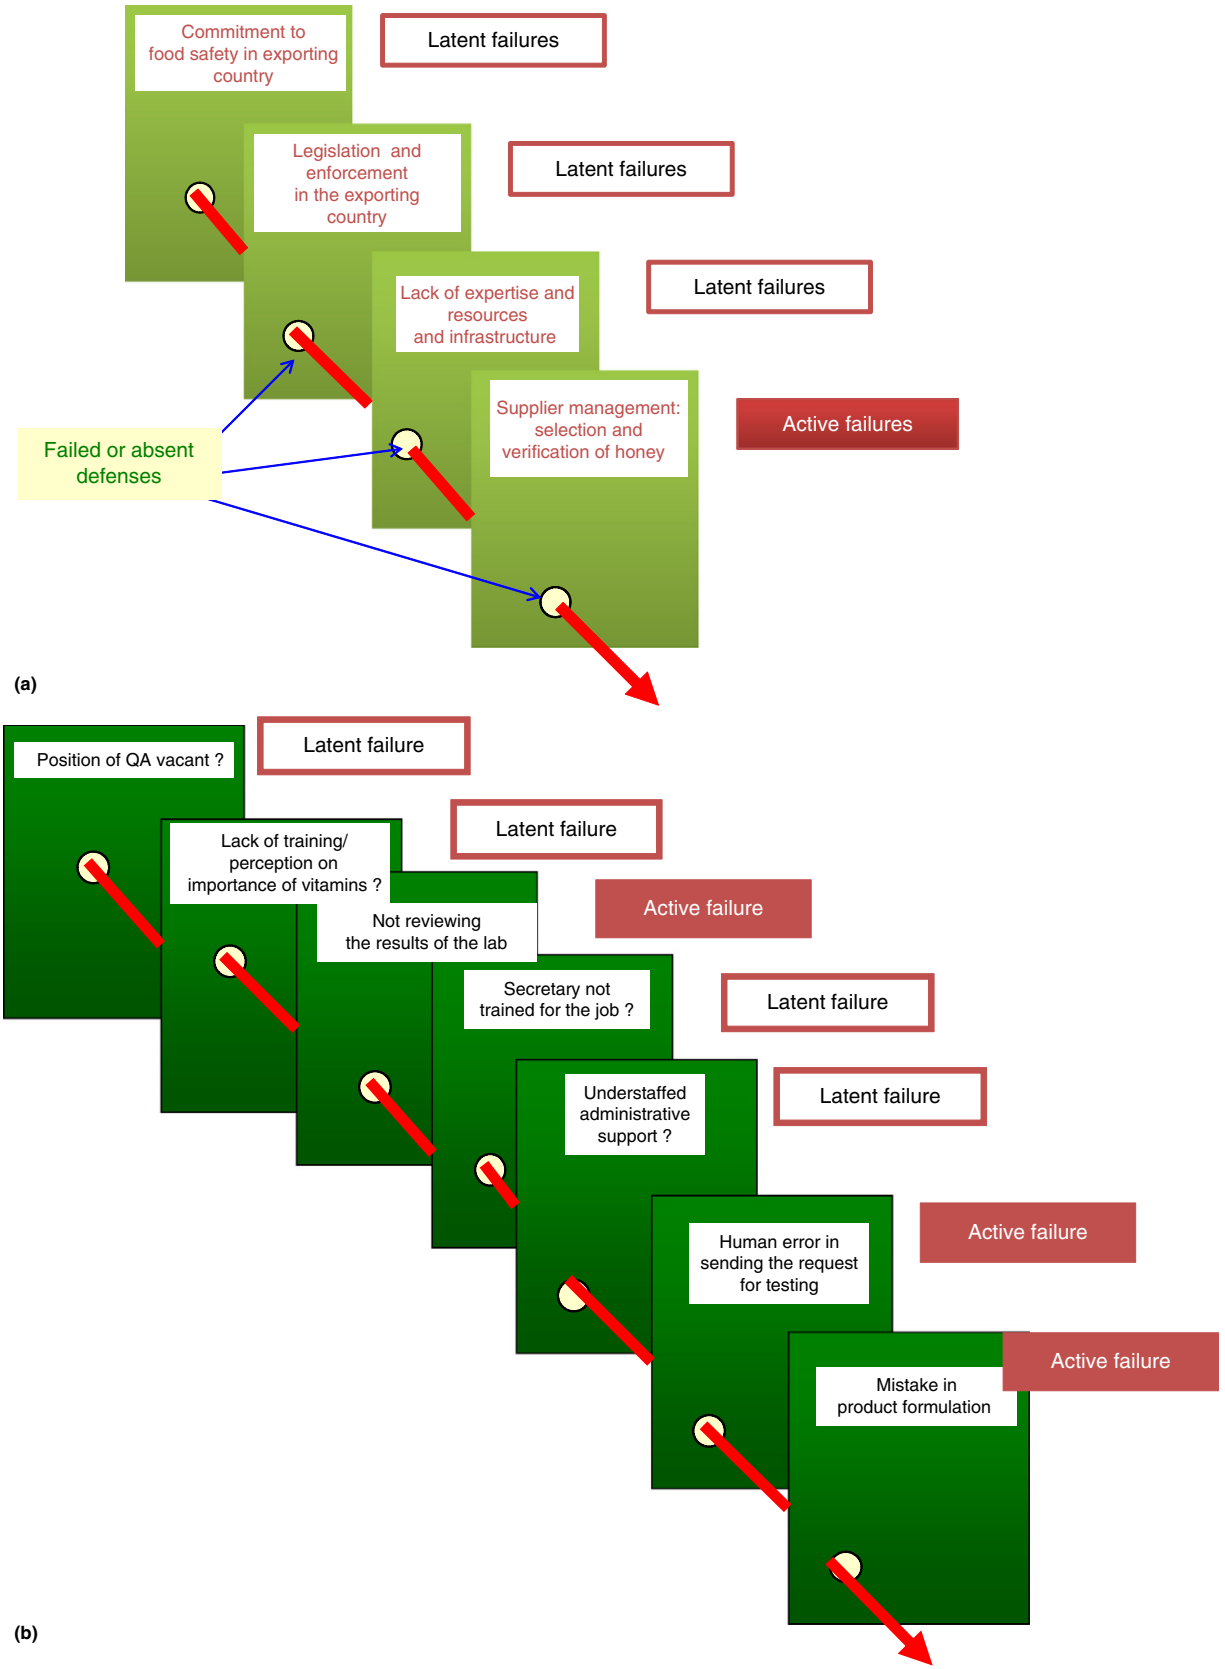

Figure 2 (a) Root cause analysis of the food safety crisis associated with chloramphenicol in honey imported from China or products containing honey. (b) An analysis of the root cause of an incident related to thiamine-deficient infant formula (Israel, 2003) based on information reported from unofficial sources. Some of the failures are mentioned for didactic reasons to illustrate the concept of root cause analysis. QA, Quality manager.

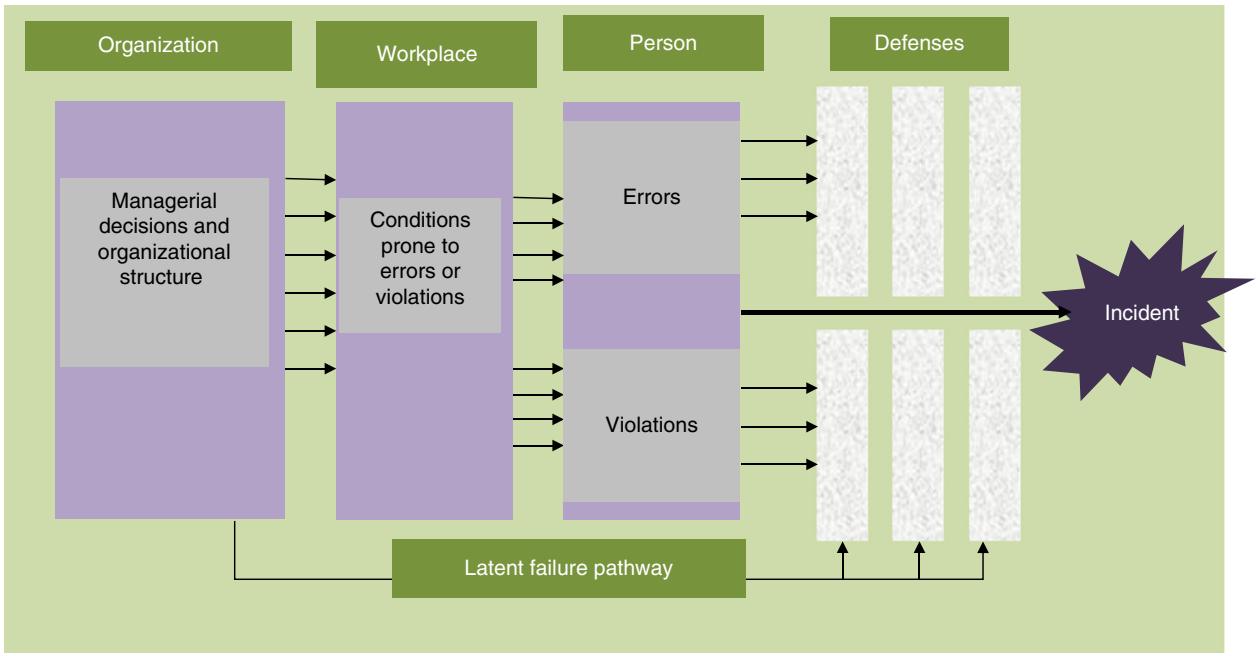

Figure 3 Levels and types of failures leading to an incident. Adapted from Reason (1995) Understanding adverse events: human factors. *Quality in Health Care* 4: 80–89.

plus additional relevant personnel, for example, human resources, purchasing, warehouse, and transport managers and so on, depending on the nature of the incident.

Structuring the Root Cause Analysis

To perform an effective route cause analysis, it is important to use a stepwise approach and take the time to gain a detailed understanding at each stage before moving on. Figure 4 shows the steps of the structured approach to root cause analysis. Although there is general agreement on the necessary actions, various texts on root cause analysis use different numbers of steps within their models. A seven-step process is used here because it covers both the analysis and the implementation and verification of corrective actions.

Step 1 Define the Fault/Incident

Members of the root cause analysis team first need to understand what has gone wrong. At this stage it is helpful to compile as much information as possible about the fault or incident, i.e., a summary of what has gone wrong, including as much as possible the sequence of events and what has been done so far in terms of immediate corrective action and incident management. This information is useful as background to the team, allowing everyone to gain an appreciation of the incident situation.

Step 2 Collect Data

Next, it is important to collect further, more detailed information that will assist in evaluating the problem. For example, this might include the following:

- Product test results.
- Lists of implicated products or processes.

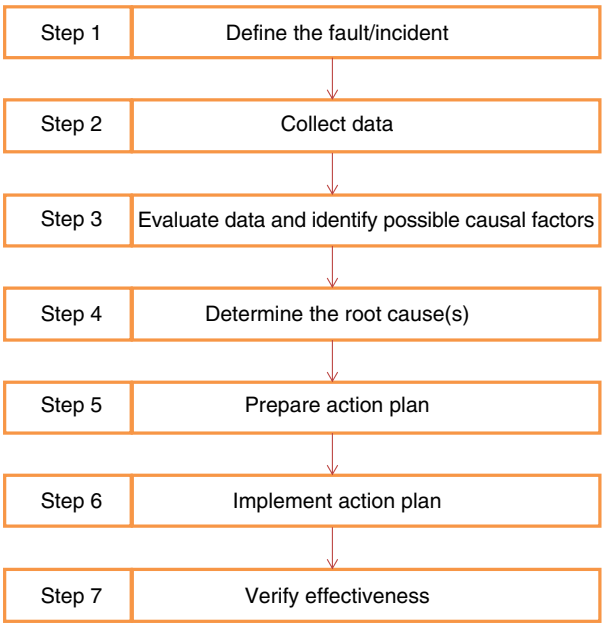

Figure 4 Root cause analysis – seven-step process.

- Lists of raw materials associated with implicated products and processes.
- Lists of packaging materials.
- Monitoring results covering dates and times thought to be implicated (the results sample(s) should be large enough to capture all relevant data around the suspect dates, i.e., building in a margin of error).
- Corrective action records covering the dates and times thought to be implicated.

- Engineering and maintenance records.
- Pest management records.
- Complaint records and customer contact information.
- Any other relevant information, for example, interview information from staff, etc.

Brainstorming will be a useful tool to make sure that all the necessary information sources can be identified and then members of the team can be allocated particular records to obtain and review on a preliminary basis.

Step 3 Evaluate Data and Identify Possible Causal Factors

To identify the possible causal factors, you need to evaluate and discuss all the data you have collected so far and also identify any further information required. This is best done by the team working together to discuss the information found and by bringing in additional personnel as necessary to help understand the situation, for example, factory floor staff who are familiar with the ongoing processing situation and additional experts (possibly external) who can advise on specific issues. Further discussion and brainstorming will help to elucidate the possible causal factors, and these all need to be recorded by the group or its appointed secretary/scribe.

Step 4 Determine the Root Cause(s)

The list of possible causes needs to be considered further by the team, evaluating how each one may have contributed to the problem. The use of tools from the root cause analysis toolbox (see section Root Cause Analysis Toolbox) will help the team understand how the possible causes may be interrelated and will assist in tracking backward to the root cause(s). Grouping techniques such as the Ishikawa Cause and Effect Analysis and questioning techniques such as the 5-Whys are particularly helpful in this context, although teams may also find some of the other tools helpful in prioritizing possible causes from their list.

The team should agree on the root cause or root causes (likely if there are distinctly different gaps or causal factors involved in an incident). The discussion can then progress onto what needs to be done to address the root cause(s). Additional tools from the root cause analysis toolkit can be helpful at this stage, such as the FMEA, which considers the current controls and then identifies recommended new controls for each cause of failure.

Step 5 Prepare Action Plan with Timescales and Responsibilities

The team's recommendations for new controls, systems, personnel, and infrastructure actions need to be built into an action plan with appropriate timescales for completion/implementation. Appropriate responsibility from the management hierarchy should be defined for each action point and personnel should be advised accordingly.

Step 6 Implement Action Plan

Individual actions on the action plan need to be implemented and signed off as complete. Depending on the nature of the actions and the timescales involved, this will need close management to make sure the plan stays on track; this can be led by members of the root cause analysis team.

Step 7 Verify Effectiveness

Verification of effectiveness is the final step in the root cause analysis process, and this is done to check that the necessary changes identified in the action plan are actually working in practice and are effective at addressing the root cause of the problem. It is also important to check at this stage that the changes have not introduced any other problems that were not foreseen. Verification can be done using audit techniques, and following verification it is likely that the business will wish to implement additional monitoring around the changes within the normal scheduled monitoring activities.

Root Cause Analysis Toolbox

A wide range of management problem-solving tools may be used in root cause analysis, and companies will find their own preferences with the experience of trying different approaches. There are no precise rules for this; it is all about getting to understand all the possible contributing factors to gain an understanding of the likely chain(s) of events leading to the incident. This will allow prioritization of necessary changes to control systems, infrastructure, and/or management practices. The following short notes are intended to help businesses understand the strengths of a selection of tools used in root cause analysis within different industries. Further, more detailed discussions on the different tools can be found in other management and problem-solving handbooks. Trial of some of these techniques within the business outside of an incident situation, perhaps as part of a business improvement project, will allow identification of preferred tools that can be used when an incident occurs.

Following is a menu of possible tools:

Brainstorming

Brainstorming is an established management tool used to capture ideas from the individuals within a group. It is particularly useful because it allows for a large number of ideas to be generated in a short time and the lateral thinking involved means that initial ideas spark off other ideas and contributions from other group members. Ideas are never criticized or commented on during the brainstorming session because this may influence or even stifle subsequent suggestions. The key point is to get as many solutions down as possible for later evaluation and it is normally necessary to allocate the role of scribe to one team member in order to record the ideas effectively.

Failure Mode and Effect Analysis (FMEA)

FMEA is well known as one of the systems that helped to originate the HACCP approach to food safety management. Its method of considering the causes and potential effects of failure is useful in looking at prevention of problems, but it can also be employed when investigating all the potential causes of an issue in an incident. Table 1 shows an example of FMEA being used to explore the causes of metal complaints due to metal detection failure.

Some FMEA methods include a risk-scoring approach although this is not often used in food manufacturing. However, it can be seen from the example in Table 1 that the sheer number of possible causes might mean that there is a need for prioritization of the recommended solutions/controls.

Table 1 Challenging metal detection failure using failure mode and effect analysis

Issue (outcome of failure)	*Failure*	*Current control*	*Possible causes of failure*[a]	*Recommended controls*
Complaints of metal in product from customers. This could result in lost credibility, lost customers, and bad publicity. Worse still, metal in product could cause customer injury and may result in prosecution.	Failure to detect metal in products[b]	Check metal detector hourly with test pieces and record result	Metal detector breakdown Metal detector not properly calibrated Wrong sensitivity check pieces Incorrect metal detector in use – wrong sensitivity Metal detector in wrong place in line Rejection mechanism faulty Rejection system not synchronized with detector Rejects not controlled Metal detector checks not done Metal detector checks done incorrectly Metal detector check reveals failure but this is not recorded Metal detector check reveals failure but no corrective action taken Staff not trained to perform metal detector checks Effectiveness of training not verified in terms of practice Workplace culture issues result in staff not taking responsibility for necessary checks	A range of controls will need to be considered around: ● Appropriate sensitivity and calibration ● Set-up verification at start up – correct sensitivity ● Maintenance systems Lockable receptacle needed that will accommodate all rejects A range of controls will need to be considered around: ● Appropriateness and coverage of training – are enough people trained and can they actually do the checks? ● How can training effectiveness be verified? ● What supervision is needed? ● Are the checks allocated within appropriate job roles and instructions? ● Management systems and commitment issues need to be investigated

[a]This will be a brainstormed list of ideas from the root cause analysis team.
[b]This is likely only one failure mode associated with the issue. Other failure modes to consider will include how the metal got into the product, for example, consideration of raw material streams and processing/equipment maintenance issues on site or possible damage of the products in distribution.
Source: Adapted from Mortimore SE and Wallace CA (1998) *HACCP: A Practical Approach*, 2nd edn. Gaithersburg: Aspen Publications.

This can be done using a simple likelihood of occurrence scheme, for example, high, medium, and low likelihood. Severity may also be considered, although it is likely that severity may be relatively similar in some cases, for example, in Table 1 the possible causes may all result in undetected metal in product.

5-Whys

The 5-Whys is a simple problem-solving technique that helps users to get to the root of the problem quickly. Made popular in the 1970s by the Toyota Production System, the strategy involves looking at any problem and asking 'Why?' and 'What caused this problem?' Normally the answer to the first 'Why' will prompt another 'Why' and the answer to the second 'Why' will prompt another and so on. It is thought that at least five questions need to be asked to track back to the root cause, hence the name the 5-Whys strategy. In reality, more than five questions may need to be asked depending on the complexity of the situation.

5-Whys helps the root cause analysis team to start at the end result and work backward toward the cause by continually asking 'Why?' until the underlying cause of the problem becomes clear. In addition to its use in root cause analysis, it is useful at the start of a remodeling or change process and is a recognized lean manufacturing technique, challenging those working on an issue to analyze any problematic situation in a logical manner, thus enhancing change and continuous improvement.

A number of benefits of the 5-Whys approach have been recorded.

- Simplicity: It is easy to use and requires no advanced mathematics or tools.
- Effectiveness: It helps to quickly separate symptoms from causes and identify the root cause of a problem.
- Comprehensiveness: It aids in determining the relationships between various causes of the problem.
- Flexibility: It works well alone and when combined with other quality improvement and troubleshooting techniques.
- Engaging: It fosters and aids teamwork and teambuilding within and outside the organization.
- Inexpensive: It is a guided, team-focused exercise. There are no additional costs.

Ishikawa Cause and Effect Analysis

This approach (also known as Fishbone Diagram) is a pictorial method (Figure 5) of organizing information about

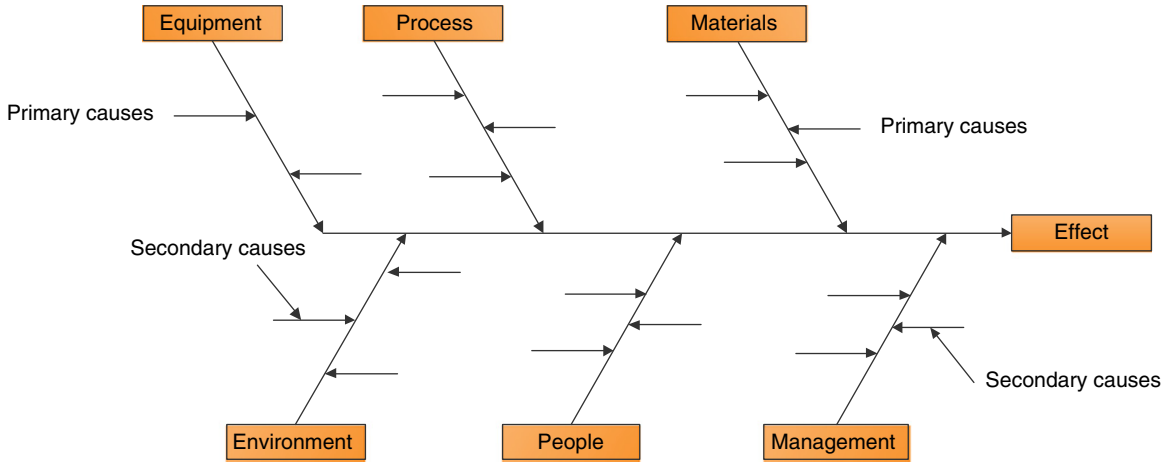

Figure 5 Example Ishikawa cause and effect analysis diagram.

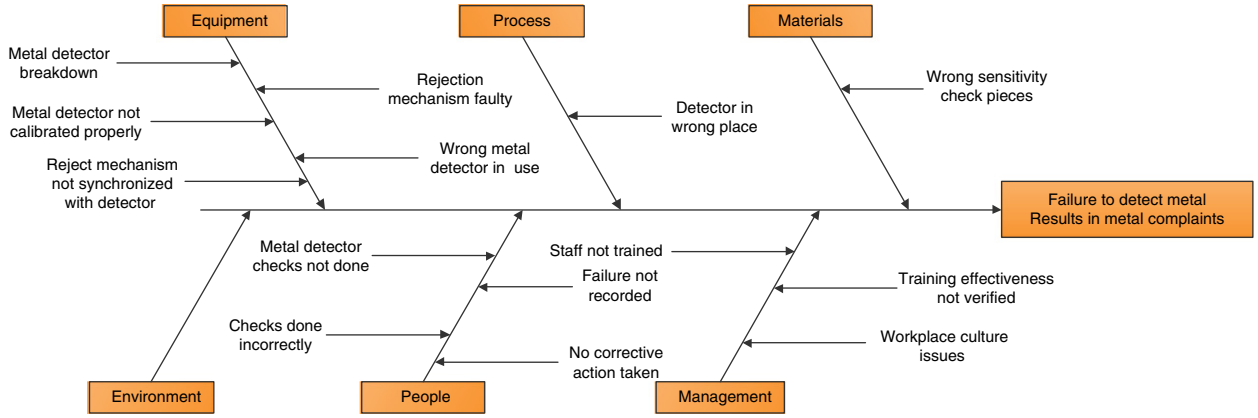

Figure 6 Ishikawa cause and effect diagram for metal contamination example.

causes and understanding the relationships between cause and effect. It is a widely used technique in problem solving, and seeks to understand the possible causes by asking questions such as 'What happened?,' 'When?,' 'Where?,' 'Why?,' 'How?,' and 'What was the impact?' The Ishikawa analysis is useful in evaluating complex situations where there may be many potential causes.

In Figure 5, it can be seen that causes are grouped into six categories of equipment, process, materials, environment, people, and management. These are commonly used category groupings in manufacturing situations; however, the categories in the Ishikawa analysis are not predetermined, so it is possible to choose your own groupings. The diagram also shows how primary and secondary causes are portrayed and in this way the causes and causes of the causes can be identified, helping to work back to the root cause. Figure 6 shows how this method can be applied to an incident, based on the metal complaints issue from Table 1.

This example (Figure 6) shows one way of grouping the possible causes identified; however, it is important to note that some causes could be grouped under more than one heading. Also in this case only the primary causes are shown; these would need to be followed up with consideration of the secondary causes and it is possible that, with further consideration, some of the points listed under the 'management' grouping might be the secondary causes affecting other groups within the diagram. There is no right or wrong way here – it is up to the team to decide how best to portray the data in their unique situation.

Hazard and Operability Studies (HAZOPs)

This is another structured and systematic technique for examining potential faults in systems. Like HACCP, HAZOP is often used as a technique for identifying potential hazards in a system, but it also focuses on identifying operability problems that are likely to lead to nonconforming products. In HAZOP, faults or incidents are thought to be caused by deviations from design or operating intentions.

In HAZOP, the identification of deviations from the design intent is achieved by a questioning process using predetermined 'guide words.' The role of the guide word is to stimulate imaginative thinking, to focus the study and elicit ideas and discussions, thereby maximizing the chances of study completeness. Further detailed guidance on how to use HAZOP,

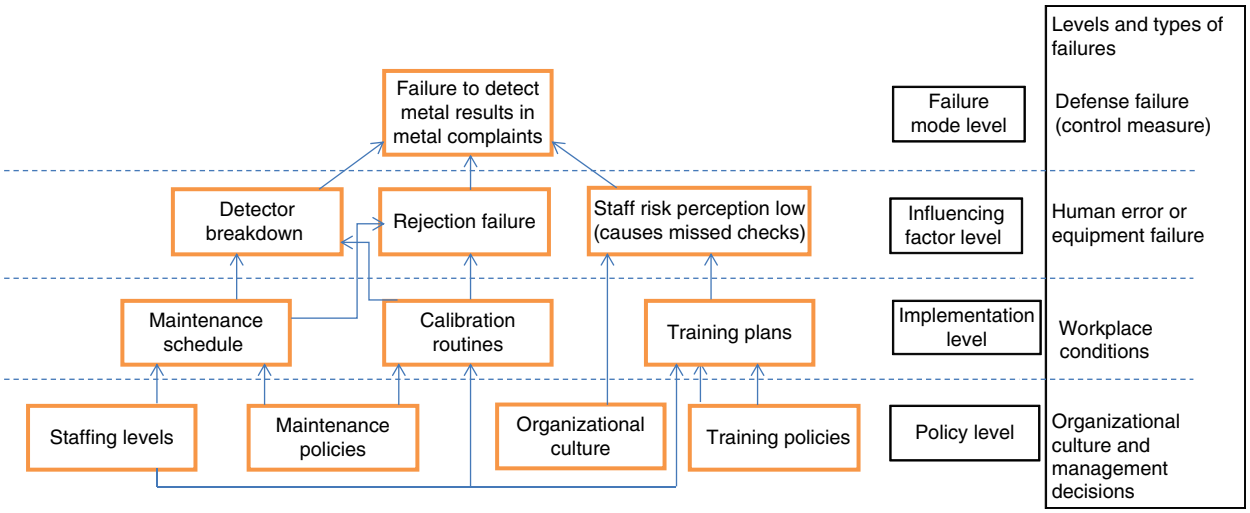

Figure 7 Example influence diagram for metal complaints (selected causes only).

including lists of typical 'guide words,' can be found in the International Electrotechnical Commission's guideline Hazard and Operability Studies (HAZOP Studies) Application Guide (BS IEC 61882:2001).

Influence Diagrams

The influence diagram approach is another technique for visual portrayal of causal factors involved in an incident. The outcome diagram is derived in similar ways to the other tools already discussed, in that expert input, group discussion, and brainstorming techniques are used. The technique differs in that it considers the possible causal factors occurring at different levels in the organization. According to Reason, the levels to be considered are as follows:

- Influencing factor level: The unsafe acts or technical failures immediately responsible for the event.
- Performance-influencing factor level: The immediate workplace conditions that shape the occurrence of human or technical failures.
- Implementation level: The underlying organizational factors that create the workplace performance-influencing factors.
- Policy level: Policy and regulatory factors that determine organizational processes occurring at the implementation level.

An example influence diagram is shown in Figure 7. In this diagram the levels and types of failures that can result in an incident that were previously outlined in Figure 2 are also highlighted on the right-hand side, indicating the practicality of application of the influence diagram approach to food safety incidents.

Additional Specialist Tools

A variety of other tools are used for problem solving in different industries. Root cause analysis teams may wish to consult the 'problem solving,' 'risk management,' and 'error avoidance' literature to identify techniques that could be trialed for suitability in the analysis of incidents. Some of these examples are more quantitative and involve risk-rating categories, which might be more difficult to apply in a food-manufacturing scenario. Further tools used in other sectors include Fault Tree Analysis, the Human Error Assessment and Reduction Technique (HEART) and the Maintenance Error Decision Aid (MEDA).

As can be seen from the list, the root cause analysis toolbox contains a plethora of techniques that will assist when faced with an incident to investigate. Using any of these tools does require practice so there is no substitute for trialing chosen tools when not in the middle of an incident; the majority of these tools are also useful in preventative improvement projects, which would be a much more suitable time to try them out. A further important point is that there is no substitute for involving the correct people in root cause analysis, so it is important to consider carefully who can contribute to the understanding of the incident and its causes.

Summary

The management of a company bears the ultimate responsibility for incidents. They are responsible for creating an organizational culture that allows employees to openly report issues and provides them with the opportunity to see that their concerns are adequately addressed. An open and fair organizational culture is fundamental for the motivation of staff and is at the core of food safety management. In the case of an incident, they have to not only follow best practice in managing the ongoing incident but also be candid with analyzing the root cause of the incident, such that they can redress the situation in a fundamental way to prevent recurrence of incidents in a long-lasting manner.

As for crisis management, the lessons learned from incidents need to be reported in a final report and disseminated both internally in the organization and externally with the food safety community at large in order to prevent the recurrence of incidents in the society.

FOOD SAFETY ASSURANCE SYSTEMS

Food Safety and Ethics

N Veflen Olsen, Nofima, Ås, Norway
Y Motarjemi, Food Safety and Risk Management Consultant, Switzerland

Glossary

Ethics Ethics is the philosophical study of the moral value of human conduct and of the rules and principles that ought to govern it.

Precautionary principle The precautionary principle states that if a product, an action, or a policy has a suspected risk of causing harm to the public or to the environment, protective action should be supported before there is complete scientific proof of a risk.

The common good approach The common good approach links ethics to social responsibility and calls attention to the common conditions that are important to the welfare of everybody.

The fairness approach The fairness approach treats all human beings equally based on some standards that are defensible.

The right approach The right approach states that humans have a right to be treated as ends and not merely as means to other ends.

The utilitarian approach The utilitarian approach deals with consequences, and tries to increase the good done and reduce the harm done.

The virtue approach The virtue approach emphasizes dispositions and habits that enable humans to act according to the highest potential of their character.

Food Safety and Ethics

Food production is a complex matter, affecting people' s life, organizations profits, and the well-being of the whole planet. It is not always straightforward to say what is right and what is wrong when it comes to production of food. Many ethical questions can be raised. Climate change, animal welfare, fair trade, health and safety of employees as well as consumers, fair treatment of employees and their social rights, economic sustainability, and use of natural resources are all important dimensions within the system of production, processing, and trade, and where every food item often includes value conflicts.

Ethics is defined as the philosophical study of the moral value of human conduct and of the rules and principles that ought to govern it. Simply stated, ethics refers to standards of behavior that tell us how human beings ought to act in the many situations in which they find themselves – as a friends, parents, children, citizens, businesspeople, teachers, professional food producers, consumers, etc. Some ethicists emphasize that the ethical action is the one that produces the greatest good and does the least harm for all those who are affected – customers, employees, shareholders, the community, and the environment 'the utilitarian approach.' The utilitarian approach deals with consequences; it tries both to increase the good done (e.g., ending hunger) and to reduce the harm done (e.g., environmental and social destructions). Other philosophers and ethicists suggest that the ethical action is the one that best protects and respects the moral rights of those affected 'the rights approach.' This approach starts from the belief that humans have a dignity based on their human nature per se or on their ability to choose freely what they do with their lives. On the basis of such dignity, they have a right to be treated as ends and not merely as means to other ends. According to the Rome Declaration, everybody has a right to adequate and safe food and a fundamental right to be free from hunger. The list of moral rights – including the rights to make one's own choices about what kind of life to lead, to be told the truth, not to be injured, to a degree of privacy, etc. – is widely debated; some now argue that nonhumans like animals and plants have rights, too. Also, it is often said that rights imply duties – in particular, the duty to respect others' rights. Aristotle and other Greek philosophers have contributed the idea that all equals should be treated equally 'the fairness or justice approach.' Present day, this idea is used to say that ethical actions treat all human beings equally, or if unequally, then fairly based on some standard that is defensible. The power distribution between retailers and suppliers have led many producers to state that multiple food retailers are abusing their position of power and engaging in practices that adversely affects the competitiveness of suppliers. To address these adverse effects it has been recommended that a code of practice be introduced to govern retailer–supplier relationships. The Greek philosophers have also contributed the notion that life in community is a good in itself and our actions should contribute to that life 'the common good approach.' This approach links ethics to social responsibility and calls attention to the common conditions

 doi:10.1016/B978-0-12-378612-8.00437-6

that are important to the welfare of everyone. Companies have a duty to be good citizens including their own workers and staff and 'to do the right things.' A very ancient approach to ethics is that ethical actions ought to be consistent with certain ideal virtues that provide for the full development of our humanity 'the virtue approach.' These virtues are dispositions and habits that enable us to act according to the highest potential of our character and on behalf of values like truth and beauty. Honesty, courage, compassion, generosity, tolerance, love, fidelity, integrity, fairness, selfcontrol, and prudence are all examples of virtues. Virtue ethics asks of any action, 'What kind of person will I become if I do this?' or 'Is this action consistent with my acting at my best?'

Each of these approaches mentioned above helps us determine what standards of behavior can be considered ethical. Different actors may not agree on the content of some of these specific approaches. They may not all agree to the same set of human and civil rights or on what constitutes the common good. They may not even agree on what is good and what is bad. Nonetheless, each approach gives us important information with which to determine what is ethical in a particular circumstance. And much more often than not, the different approaches do lead to similar answers.

So what are the ethical dilemmas in food safety? Is it reasonable to forbid sales of cheese made with unpasteurized milk? Here, food safety is set up against people's pleasure of eating tasty cheese, traditional food cultures, and the food industries economical interest. Is unpasteurized cheese safe enough? Similar questions can be asked about raw minced meat (steak tartar) served in some restaurants, raw milk sold in some countries, or worse, when raw milk is given to children. In theory, a fully informed consumer might decide which food-related risk to take and which to avoid. But what does it mean to be fully informed? Can we expect that all consumers are able to collect the detailed information about the wide array of food safety issues and make their own decisions? Are there any good strategies for providing relevant information in such a way that consumers understand the risk? Is it the correct thing to delegate this responsibility to responsible authorities? What does it mean in terms of responsibilities for authorities? And what if the consumers do not trust these authorities? Finally, who becomes responsible when illness occurs: Industry which has provided a contaminated product, authorities who have failed to educate consumers, or consumers themselves who have not taken the necessary precautions?

Another key question is when a food industry transfers responsibility of safety to consumers without providing proper warnings, crystal clear instructions on safety measures, or even worse, market and promote a product in a society when it knows that consumers would not be able or have means, to ensure its safety. The latter issue was raised with the question of breast milk substitute in the developing countries, until WHO established the Code of Breast milk substitute that responsible companies comply with. The issue of warnings on food package is still not well addressed in most legislation and the clarity with which drug providers or electrical equipment or aviation companies provide information has not yet been established in the food industries. This has made some companies to write an ambiguous text that do not raise concern of consumers, but in case of an incident, the company is covered and can decline any responsibility.

Food safety management relies very much on a fair and professional management of people, including ensuring that employees are competent for their job, have received the proper training and briefing about their responsibilities. They are given the means and authority to do a professional job, and also setting the right reporting structure minimizing conflict of interest in audits and investigation of incidents, and most of all a company culture which fosters reporting and openly discussing problems, protecting and rewarding whistleblowers, and a management which walk the talk and follow its own policies. Unfair practices cannot only lead to discouragement and an uncaring attitude of employees, but occasionally has also been the source of outrage and sabotage of the food (i.e., tampering), thus a risk for consumers. The company culture is an area which is not legislated and enforced by law, but is one of the most important aspects of the ethical practice of a company as it impacts on all aspects of operations, including safety and health and the social right of employees, as well as safety of products and health of consumers.

Finally, one of the most fundamental aspects of ethics in food industry is the commitment and 'real will' of the company to build a solid food safety assurance system or just to do the minimum necessary to meet the requirements of legislation and certification bodies. As safety of food products is the outcome of the food safety assurance system (including the professional management of its staff) of food companies, no matter how comprehensive and strong the regulatory system of a country may be, it cannot replace the everyday vigilance of managers, workers of a company who have to oversee the safety of products.

The Precautionary Principle

The precautionary principle states that if a product, an action, or a policy has a suspected risk of causing harm to the public or to the environment, protective action should be supported before there is complete scientific proof of a risk. In the absence of scientific consensus, the principle implies that there is a social responsibility to protect the public from potential harm. This is a 'better safe than sorry' or 'caution in advance' principle that applies both to human health and to environmental protection.

One of the primary foundations of the precautionary principles, and globally accepted definitions, results from the work of the Rio Conference, or 'Earth Summit' in 1992. Principle #15 of the Rio Declaration notes:

"In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation."

The application of the precautionary principle has been made a statutory requirement within the European Union (EU), and according to a Food and Agriculture Organization of the United Nations Expert Consultation report on food safety

international, food safety organizations must make clear that science, although an important tool, is not sufficient in itself for food risk analysis and that it needs to operate within an ethical framework. The problematic cases are the ones where there are disagreements about the value judgments made in the risk assessment. For Novel Food, new technologies, or newly identified hazards, the answer to what is 'safe' may not be the subject of a consensus. When both the likelihood of damage and the consequences of damage are unknown, then risk assessment becomes difficult and the assessors face ethical dilemmas. Genetically modified organisms (GMO), is one example of a new technology which has created a lot of debate. The presence of different interest groups and diverse citizens' values in different political arenas triggered a range of policy responses to GMOs in the 1990s. Although GMO was strongly supported by the scientific and biotech industry in the USA, and lead to a flourish of GM crops, European citizens were strongly opposed by GM plants. Consumers were skeptical and talked about 'unnatural Frankenstein's food.' They lacked confidence due to their governments' response to a series of food scares in the 1990s. Today, the GMO regulatory framework in the EU is different from the one in US and more in line with the public's perception of risk than with the scientific definition of risk. The precautionary principle is applied in the EU and is constantly challenged. A main ethical question which raised a controversy with regard to GM foods was few years ago when EU countries would, as part of food aid, propose GM foods to the developing countries (Africa). In 2002, Zambia announced it would not accept GM food aid in any form. So the question was, why a technology and product rejected by the European population will be good for the African population? Most African countries approach GM technology applied to crops with caution. "Why shouldn't we be wary of this technology and its possible long-term health impacts, if the EU is? If it is not good for them, why should it be good for us?" said Tewolde Egziabher, Ethiopia's director of the Environmental Protection Agency. Positions were polarized to a great extent after a quote from a US state department official, "Beggars can't be choosers," hit the headlines. It prompted the then president, Levy Mwanawasa, to say hunger was no reason for feeding his people "poison."

The evolutionary aspect of the food system, influences risk assessment of food safety and triggers some ethical dilemmas. Although, consumers' food variety increases and the food industry potentials for new business grow, there are food safety issues to consider. The food market is becoming more and more global. Not only food, but also food pathogens are distributed around the world. In Norway, sugar peas from Kenya lead to an outbreak of dysentery in 2009, probably due to consumption of raw products. In Kenya, people boil or fry vegetables before consumption. This is not the case in Norway where unpeeled fruit and raw vegetables are consumed frequently. In many ways Norway is a food safety oasis in Europe, with a livestock population virtually free from Salmonella and where only one out of nine national outbreaks of infectious intestinal diseases linked to lettuce, sprouts, sugar peas, and basil in the past 20 years came from Norwegian produce. The problem is that consumers' food safety habits and routines, inherited from parents, are not always adapted to handle new food scares from imported products. When food and food pathogens change, whereas food preparation routines stay the same, then food safety becomes an issue. The solution to this food safety problem raises ethical questions related to freedom of choice, economic prosperities for developing countries, distribution of pathogens into clean areas, etc.

A related issue is the question, to what extent food safety should be regulated and harmonized across the world? On the one hand harmonization of regulation is important from a human rights perspective as all human beings, regardless of their color, race, gender, and culture should have the right to the same level of health protection and thus food safety, and products rejected in one country should not be dumped in another. However, for various reasons, presently the same level of safety is not achievable in all countries and trying to meet a high standard of food safety in some countries may be to the detriment of causing hunger and malnutrition. On the other hand, failing to harmonize food safety regulations has lead to a double standard in some countries, i.e., foods produced for export have a higher standard of quality and safety, whereas foods of inferior safety and quality standard, possibly with higher level of contamination, is directed to the domestic market and local people. However, can one deny a higher level of health protection to countries which can meet these?

Ethical Decision Making

Making good ethical decisions requires a trained sensitivity to ethical issues and a practiced method for exploring the ethical aspects of a decision and weighing the considerations that should impact our choice of a course of action. Having a method for ethical decision making is absolutely essential. The more novel and difficult the ethical choice we face, the more we need to rely on discussion and dialog with others about the dilemma. Only by careful exploration of the problem, aided by the insights and different perspectives of others, can we make good ethical choices in such situations.

In a company where ethics is a valued principle, the management ensures that food safety is managed professionally and objectively. However, the ethic of its management becomes conspicuous particularly in time of an incident or a conflict. This will be demonstrated by questions such as to what extent the company will:

1. voluntarily acknowledge a contamination or and if necessary recall its products,
2. investigate the root cause of the incident up to the management level,
3. accept loss of benefits to protect consumers,
4. act transparently and reveal information on the incident and its cause, and also,
5. take punitive actions against those who have knowingly and irresponsibly violated the policies (note: Errors are different from violations and should be not subject of punitive actions, see other articles).

In the health care or aviation sectors, reporting of noncompliance or problems, and independence in investigations of incidents is much more advanced and can be a model for the food sector if food safety is to be strengthened.

At the national level, ethics of the regulatory authorities is proven by the system of decision making that they put in place to ensure:

1. independence of health sciences and institutions generating scientific and technical data,
2. an unbiased decision making process with separation of risk assessment and risk management function,
3. priority to consumer health over economic considerations, and
4. mechanism for reporting malpractices and noncompliances, for example, protection of whistle-blowers.

Other Aspects of Ethics of Relevance to Food Industry

Over and above aspects of ethics in relation to food safety, few words should also be said on other practices in the industry that are unethical. For instance, abuse and mistreatment of animals, child labour, negligence leading to environmental damages, or fraud and deceitful practices such as the recent horse and pork meat scandal, which was revealed as this article is going into publication.

In the latter mentioned case, the deceitful practice of the food industry was perhaps not affecting safety of products *per se* but in other cases, such as the incident of melamine in USA in 2007 and repeated again in China in 2008, it did have serious health consequences for consumers.

Although the fraud of replacing beef with horse and pork meat took place at the suppliers of minced meat products, the responsibility of the processors and manufacturers who were manufacturing and marketing ready-to-eat foods is not less, as they were responsible for verifying their suppliers. The gravity of the scandal does not only lie in the fact that some people unknowingly and against their personal values ate horse or pork meat, but the fact that so many people were aware of the fraud, yet they turned a blind eye. Under such circumstances the door is open to any wrongdoings and consequently there cannot be a guarantee for food safety as what cannot be anticipated cannot be prevented. This scandal also revealed the poor conditions in which horses were maintained and transported.

To promote ethical practices in companies, the public at large should value ethic and be outspoken about it, for instance by the choice of the products they buy. The experience from the bovine spongiform encephalopathy crisis showed the power of consumer pressure in promoting health considerations in the decision making process. Subsequently, giving priority to health over economic considerations has today become a key principle in risk management. Similarly, in a national referendum in 2013 in Switzerland, referred to as the Minder Initiative, the Swiss public expressed its dismay with disproportionate high salaries of managers in companies, and forced politicians to take legislative measures to limit such practices, showing the power of public and consumers in changing practices and promoting ethics.

However, over and above that of the general public, the responsibility of poor ethical practices in any company, or any other organization, falls on the staff of the organization, who should also react and challenge the decision-makers to force them to behave ethically and respect the international standards and charters in the areas of human rights, environment, animal welfare, consumer health, etc.

Conclusion

The likelihood of becoming sick from the next meal has probably never been less than it is today, but the long-term consequences of today's food production is less known. The production process has increasingly become complex and less transparent and consumers are no longer in control of the production system. They need to trust food producers, food manufacturers, and retailers. Consumers are worried, some of these worries are directly linked to the risks involved, be it real or perceived. Other worries are more linked to ethical questions related to well-being, free choice (autonomy), and fairness (justice). Availability of safe food needs to be addressed in relation to factors, such as respect for consumer choice, right to information on safety, universally affordable food, adequate income, and working conditions for employees and workers, fair practice in trade, animal welfare, and sustainability of biotic populations. Also, consumers are worried about new technologies and if these new techniques take into consideration their health and safety, or if they merely are developed for business interest and the benefits of producers. Some consumers wonder to what degree science is being developed impartially, and if governments and public health authorities give priority to consumer's health in their opinion on risks and risk management options, and if incidents are investigated independently and transparently.

A dialog about the ethical implications of food production, processing, policy, supply, and consumption, may help involved partners making better decisions. The discussion needs to be lifted up to a level above what each company at any given point in time feels is best for them.

Aristotle says that identifying the good with pleasure is to prefer a life suitable for beasts.

"It is better to be a human being dissatisfied than a pig satisfied; better to be **Socrates** dissatisfied than a fool satisfied. And if the fool, or the pig, are of a different opinion, it is because they only know their own side of the question… "

Every company has a social responsibility. Not behaving according to accepted norms for ethical behavior may not only have consequences for food safety, but also on a company's image, reputation, and performance. Ethics is not a question of thoughtless and slavish worship of rules, and to scrupulously checking every action against a table of do's and don'ts. The fundamental question of ethics is not 'What should we do?' but 'What image would we like for our company?' Will we accept compliances, deceive full negligence or noncompliance as long as we are not caught, or will we be vigilant in any condition?

"Integrity is doing the right thing, even when no one is watching (Clive Staples Lewis,1898–1963)," and ethics is to the industry what integrity is to a person.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Contents

FAO/WHO Codex Alimentarius Commission (CAC)

T Heilandt, FAO, Rome, Italy
CA Mulholland and M Younes, World Health Organization, Geneva, Switzerland

Glossary

Contaminant Any substance not intentionally added to food, which is present in such food as a result of the production (including operations carried out in crop husbandry, animal husbandry and veterinary medicine), manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food or as a result of environmental contamination. The term does not include insect fragments, rodent hairs and other extraneous matter.

Food Any substance, whether processed, semi-processed or raw, that is intended for human consumption, and includes drink, chewing gum and any substance that has been used in the manufacture, preparation or treatment of "food" but does not include cosmetics or tobacco or substances used only as drugs.

Food additive Any substance not normally consumed as a food by itself and not normally used as a typical ingredient of the food, whether or not it has nutritive value, the intentional addition of which to food for a technological (including organoleptic) purpose in the manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food results, or may be reasonably expected to result, (directly or indirectly) in it or its by-products becoming a component of or otherwise affecting the characteristics of such foods. The term does not include "contaminants" or substances added to food for maintaining or improving nutritional qualities.

Food hygiene Comprises conditions and measures necessary for the production, processing, storage and distribution of food designed to ensure a safe, sound, wholesome product fit for human consumption.

Hazard A biological, chemical or physical agent in, or condition of, food with the potential to cause an adverse health effect.

Pesticide Any substance intended for preventing, destroying, attracting, repelling, or controlling any pest including unwanted species of plants or animals during the production, storage, transport, distribution and processing of food, agricultural commodities, or animal feeds or which may be administered to animals for the control of ectoparasites. The term includes substances intended for use as a plant growth regulator, defoliant, desiccant, fruit thinning agent, or sprouting inhibitor and substances applied to crops either before or after harvest to protect the commodity from deterioration during storage and transport. The term normally excludes fertilizers, plant and animal nutrients, food additives, and animal drugs.

Risk A function of the probability of an adverse health effect and the severity of that effect, consequential to a hazard(s) in food.

Risk analysis A process consisting of three components: (1) Risk assessment that is a scientifically based process consisting of the following steps: (i) hazard identification, (ii) hazard characterization, (iii) exposure assessment, and

(iv) risk characterization. (2) Risk management, which is the process, distinct from risk assessment, of weighing policy alternatives, in consultation with all interested parties, considering risk assessment and other factors relevant for the health protection of consumers and for the promotion of fair trade practices, and, if needed, selecting appropriate prevention and control options. (3) Risk communication, which is the interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Traceability/product tracing The ability to follow the movement of a food through specified stage(s) of production, processing and distribution.

Veterinary drug Any substance applied or administered to any food producing animal, such as meat or milk producing animals, poultry, fish or bees, whether used for therapeutic, prophylactic or diagnostic purposes or for modification of physiological functions or behavior.

Safe, Good Food for Everyone – The Need for an International Food Code

Foodborne illness is a major cause of morbidity and mortality around the world. Outbreaks of foodborne illness can also damage trade and tourism and lead to loss of earnings, unemployment, and litigation. People have the right to expect their food to be safe, of good quality, and suitable for consumption.

In the beginnings of agriculture and food trade, traditional knowledge, based on experience and trial and error, directed what to eat and what not and how to keep food safe. People grew their own food or bought it in exchange for services, goods, or money from someone they knew, which ensured the link between them for safety, quality, and fairness. Although some may still live that way, for most people food comes from producers who they have never met and from places they have never seen. Wholesale markets that supply local sellers, source food from anywhere around the world and buyers order items that they have not seen, touched, or smelled, thus, they have to rely on the product descriptions and guarantees that the sellers provide.

The need for rules and codes for safety and quality in food production, transport, and trade grew over time as the local food chain, involving a handful of actors, transformed into a global chain involving millions of people. National food laws exist in most countries and in order to facilitate trade and ensure harmonization, the idea of a global food code (*Codex Alimentarius*) was born.

Codex Alimentarius and Codex Alimentarius Commission

The Codex Alimentarius Commission (the Commission) – jointly sponsored by the Food and Agriculture Organization of the United Nations (FAO) and the World Health Organization (WHO) – held its first session in 1963. The Codex Alimentarius is a collection of international food standards, guidelines, and codes of practice whose main purpose is to protect the health of consumers and ensure fair practices in food trade. The Codex Alimentarius thus covers food safety matters (residues, hygiene, additives, contaminants, etc.) and quality matters (product descriptions, quality classes, labeling, and certification). Its internationally agreed texts allow harmonization of national requirements and, in this way, facilitate international trade.

The Codex Alimentarius serves as the basis for many national food standards and related regulations. All Codex standards and related texts, as well as all meeting information, are in the public domain and available at: www.codexalimentarius.org.

The Role of Codex Standards in International Trade

The Codex Alimentarius is a recommendation to its members. Application of Codex standards, guidelines, and codes of practice is voluntary until implemented in national or regional law. However, since 1995, after the establishment of the World Trade Organization (WTO) following the Uruguay Round of Trade Agreements, Codex standards and related texts have become international references for food safety under the WTO's Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement). Similarly, the standards of the World Organisation for Animal Health (OIE) became the reference for animal health and those of the International Plant Protection Convention (IPPC) became the reference for plant health.

For WTO members this means that, as long as they apply Codex standards for food safety measures, no other WTO member can challenge such measures as unjustified barriers to international trade. If a country wants to set stricter standards, this needs to be justified scientifically through a risk analysis process. In case of a dispute, the WTO provides the relevant dispute settlement process.

Codex texts are also recognized as international standards by the WTO Agreement on Technical Barriers to Trade (TBT) and have been used in dispute settlements. Contrary to the SPS agreement, the TBT agreement does not mention any specific standard setting organization. However, Codex texts have been used in TBT dispute settlement procedures.

How the Codex Alimentarius Commission Works

The Commission and its specialized technical subsidiary bodies (Figure 1) provide structured, neutral meetings for discussion of all topics related to food safety and trade within its mandate. Representatives from governments, consumer groups, industry, and academia meet to exchange views

Figure 1 Joint FAO/WHO Food Standards Programme (status 2012).

about food safety and trade and to adopt standards or related texts.

Statutes

The statutes are the legal basis for the Commission's work and formally reflect the concepts behind and reasons for its establishment. Article 1 of the statutes contains purposes, terms of reference, and objectives. Article 2 defines eligibility for membership of the Commission, which is open to all Member States and Associate Members of FAO and WHO.

Rules of Procedure

The Rules of Procedure of the Codex Alimentarius Commission describe: Conditions of membership; appointment and responsibilities of Commission officers (chairperson and three vice-chairpersons); appointment and responsibilities of the other members of the Executive Committee (six regional coordinators and seven members elected on a regional basis); appointment and role of the Secretary; establishment of an Executive Committee to meet between Commission sessions, to act on behalf of the Commission as its executive organ; frequency and operation of Commission sessions; nature of agendas for Commission sessions; voting procedures; observers; preparation of Commission records and reports; establishment of subsidiary bodies; procedures to be adopted in the elaboration of standards; allocation of a budget and estimates of expenditure and; languages used by the Commission.

Representation of Members and Current Meeting Schedule

In June 2012, 99% of the world's population was represented in the Commission through 184 member countries and one Member Organization (European Community). Currently, the Commission meets annually at the headquarters of FAO or WHO. Special or extraordinary sessions can be scheduled if needed. Representation at sessions is on a country basis. National delegations are led by senior officials appointed by their governments. Delegations may include representatives of industry, consumers' organizations and academic institutes. Countries that are not yet members of the Commission sometimes attend in an observer capacity. To facilitate continuous contact with member countries, members have established country Codex Contact Points, and many member countries have National Codex Committees to coordinate activities nationally.

Observers

In June 2012, over 200 International Governmental Organizations and International Nongovernmental Organizations (NGOs) had observer status with the Commission. The Codex process allows such organizations to put forward their points of view at every stage except in the final decision, which is the exclusive prerogative of members.

Codex Strategic Plan

The Commission is guided in its work by a strategic plan, which is reviewed every 5 years.

The vision statement of the present plan (2008–13) reads: "The Codex Alimentarius Commission envisages a world afforded the highest attainable levels of consumer protection including food safety and quality. To this end, the Commission will develop internationally agreed standards and related texts for use in domestic regulation and international trade in food that are based on scientific principles and fulfill the objectives of consumer health protection and fair practices in food trade."

The plan contains the following five goals which have been broken down further into a number of activities:

- Goal 1: Promoting Sound Regulatory Frameworks.
- Goal 2: Promoting Widest and Consistent Application of Scientific Principles and Risk Analysis.
- Goal 3: Strengthening Codex Work-Management Capabilities.
- Goal 4: Promoting Cooperation between Codex and Relevant International Organizations.
- Goal 5: Promoting Maximum and Effective Participation of Members.

Codex Secretariat and Administration

The Codex Secretariat is a team of less than 20 professional and technical staff located in FAO headquarters in Rome. The Secretariat deals with all aspects of the functioning of the Commission and its subsidiary bodies (e.g., preparing agendas and distributing working documents and drafting the reports of the sessions) and with the updating and publication of the Codex Alimentarius.

Work on the Codex Alimentarius

Standard Setting Process

As stated in Article 1 of the Commission's Statutes, one of the principal purposes of the Commission is the preparation of food standards and their publication in the Codex Alimentarius.

The process for preparing standards is open and transparent and ensures that all interested parties can be heard and contribute. It consists of a number of steps that starts with the submission of a project document to the Executive Committee and the Commission either by a subsidiary body or a Codex member in line with the requirements set out in the Procedural Manual justifying the need for new work and setting out the time frame. This formal proposal is often preceded by informal discussions in subsidiary bodies where members inform others of their interest and reasoning and evaluate if there is support for the project.

Step 1: Decision by the Commission that a standard be developed as proposed based on the criteria in the Procedural Manual and the priorities in the strategic plan. The Commission selects the subsidiary body to be responsible for steering

the standard through its development. If necessary, a new subsidiary body may be created.

Step 2: Preparation of a proposed draft standard is arranged by the Codex Secretariat and circulated to members and observers for comments.

Step 3: Comments are considered by the relevant subsidiary body that may present the text to the Commission as a draft standard for adoption at Step 5, or send it back for redrafting. Where relevant, the draft will be referred to the Codex Committees responsible for labeling, hygiene, additives, contaminants, and methods of analysis for endorsement of any special advice in these areas.

Steps 6 and 7: A second round of comments and discussions takes place in the subsidiary body before the standard is recommended to the Commission for adoption at Step 8.

Steps 6 and 7 may be omitted if there is a consensus on this in the subsidiary body and the Commission (adoption at steps 5/8) or it may be decided when starting a project that it should be finalized in 5 steps (accelerated procedure, adoption at step 5A).

Most standards take a number of years to develop. Once adopted by the Commission, a Codex standard is added to the Codex Alimentarius. A recent study showed that the speed of standard setting in Codex was 4.2 years overall and 3.5 years for food safety standards. The minimum time needed for adopting a standard is presently 1 year i.e., from one session of the Commission to the next. For example, the maximum limits for melamine after the food safety crisis related to adulterated milk were adopted in 1 year. Faster adoption could be possible only through an extraordinary session of the Commission.

The Commission and its subsidiary bodies keep Codex standards and related texts up to date to ensure that they are consistent with current scientific knowledge and the needs of the member countries. Countries now require less prescriptive standards, especially for commodities, than those developed in the 1970s and 1980s.

In recent years, many older, detailed individual product standards have been consolidated into more general or group standards, which allow wider coverage and innovation in the development of new food products. The procedure for revision or consolidation follows that used for the initial preparation of standards, but can be shortened in the case of editorial or consequential amendments.

Decision Making

The Commission and its subsidiary bodies strive to find a consensus on all issues under discussion. Voting is possible in accordance with the procedures, but past experience has shown that standards adopted by a vote have a lower acceptance as the original controversy does not disappear with the vote. For this reason, some issues remain on the agenda for a significantly longer time than the average because it takes longer to come to a consensus.

Subsidiary Bodies

The Commission may establish three kinds of subsidiary bodies.

- Codex Committees – which are of a standing nature (but may be adjourned or abolished) prepare draft standards for submission to the Commission or deal with Codex procedures;
- Ad hoc intergovernmental task forces – which are established for one specific purpose and are dissolved when their task is completed;
- Coordinating Committees, through which regions or groups of countries coordinate food standards activities in the region, including the development of regional standards.

There may be as many as 20 Codex Committee meetings in any 12-month period. With the exception of the Executive Committee and Coordinating Committees, Codex Committees and task forces are hosted by member countries, which are responsible for the cost of the committee's maintenance and administration and for providing the chairperson. Sessions are usually held in the host countries but recently an increasing number of industrialized country hosts have made use of the possibility to hold sessions in developing countries under cohosting agreements. The designation of host countries for the committees is a standing item on the agenda for the Commission.

The Executive Committee as well as the Commission meetings alternate between the headquarters of FAO and WHO (Rome and Geneva), and all costs are covered by the Codex budget. Coordinating Committees are usually hosted in the country of the coordinator (but may be cohosted in other countries) and the main costs (interpretation and translation) are funded by the Codex budget which is covered entirely by FAO and WHO.

General Subject Committees

General Subject Committees (horizontal committees) work on issues that can apply to any commodity or groups of commodities. They develop concepts and principles applying to foods in general, specific foods, or groups of foods, and endorse or review relevant provisions in Codex commodity standards. Based on the advice of expert scientific bodies, they develop major recommendations pertaining to consumers' health and safety.

Six of the General Subject Committees have the responsibility of ensuring that specific provisions in Codex commodity standards are in conformity with the Commission's main general standards and guidelines in their particular areas of competence. They are the committees on Food Additives; Contaminants in Foods; Food Hygiene; Food Labeling; and Methods of Analysis and Sampling.

These committees also develop standards, maximum limits for additives and contaminants, and codes of practice or other guidelines for either general application or in specific cases where the development of a complete commodity standard is not required.

For example, the Committee on Food Hygiene has developed a Code of Hygienic Practice for Spices and Dried Aromatic Plants, and the Committee on Food Additives and Contaminants (divided into two committees in 2006) has developed a Standard for Maximum Levels of Lead in Foods.

The committees on Food Labeling and on Nutrition and Foods for Special Dietary Uses have worked together to prepare the Codex Guidelines on Nutrition Claims.

The Committee on Pesticide Residues and the Committee on Residues of Veterinary Drugs in Foods prepare Maximum Residue Limits (MRLs) for these two categories of chemicals used in agricultural production. The MRLs are based on scientific advice regarding the safety of the residues that remain after the substances are used in accordance with defined good agricultural or veterinary practices.

The Committee on Food Import and Export Inspection and Certification Systems deals with the application of standards to foods moving in international trade, in particular to the regulatory measures applied by governments to assure their trading partners that foods and their production systems are correctly regulated to protect consumers against foodborne hazards and deceptive marketing practices. The guidelines developed by the Committee include advice on how governments should respond to emergencies in the food safety system, including channels of communication to the public and to other governments by means of the International Food Safety Authorities Network (INFOSAN) emergency information system operated by WHO and FAO.

The Committee on Nutrition and Food for Special Dietary Uses has a double role of serving as a general committee for questions of nutrition, and as a commodity committee for special dietary foods such as baby foods or gluten free foods.

The Committee on General Principles advises the Commission on such basic matters as definitions, the Rules of Procedure, rules and working procedures for the establishment and operation of Codex Committees and task forces, relations with other organizations, and the general principles that underlie the preparation of all Codex standards, codes of practice, and other texts.

Commodity Committees

The responsibility for developing standards for specific foods or classes of food lies with the Commodity Committees (vertical committees). Commodity Committees convene as necessary and go into recess or are abolished when the Commission decides their work has been completed.

There are currently four Commodity Committees that meet regularly: Fats and Oils, Fish and Fishery Products, Fresh Fruits and Vegetables, and Processed Fruits and Vegetables.

The following Commodity Committees work through correspondence or are adjourned: Milk and Milk Products; Cereals, Pulses and Legumes; Cocoa Products and Chocolate; Meat Hygiene; Natural Mineral Waters; Sugars and Vegetable Proteins.

Host countries convene meetings of Codex subsidiary bodies at intervals of between 1 and 2 years, according to need.

Ad hoc Intergovernmental Task Forces

In 1999, the Commission realized that its committee structure was too inflexible to cope with the demand for standards and guidelines across an ever-widening range of subjects. It decided to create a third type of subsidiary body the ad hoc Intergovernmental Task Forces, which are Codex Committees with very limited terms of reference established for a fixed period of time. To date, the Commission has established the following ad hoc Intergovernmental Task Forces:

- Task Force on Animal Feeding – 1999–2004, 2012–present;
- Task Force on Foods Derived from Biotechnology – 1999–2003 and 2005–09;
- Task Force on Fruit and Vegetable Juices – 1999–2005;
- Task Force on the Handling and Processing of Quick Frozen Foods – 2006–07.
- Task Force on Antimicrobial Resistance – 2006–11.

Coordinating Committees

Coordinating Committees ensure that the work of the Commission is responsive to regional interests and to the concerns of developing countries. They meet at 2-year intervals. The country that chairs the Coordinating Committee is also the Regional Coordinator for the region concerned. These Committees have no standing host countries but usually meet in the country that is the Coordinator as nominated by the relevant Coordinating Committee and confirmed by the Commission. There are six Coordinating Committees, one each for the following regions: Africa; Asia; Europe; Latin America and the Caribbean; Near East; and North America and the Southwest Pacific.

Contents of the Codex Alimentarius: Standards, Guidelines, and Codes of Practice

Codex Standards

By far, the largest number of specific standards in the Codex Alimentarius is the group called 'commodity standards.' The major commodities included in the Codex are:

- Cereals, pulses (legumes), and derived products including vegetable proteins.
- Fats and oils and related products.
- Fish and fishery products.
- Fresh fruits and vegetables.
- Processed and quick-frozen fruits and vegetables.
- Fruit juices.
- Meat and meat products; soups and broths.
- Milk and milk products.
- Sugars, cocoa products, and chocolate and other miscellaneous products.

Commodity standards follow a common format set out in the Procedural Manual consisting of the following categories:

- Scope – includes the name of the food to which the standard applies and, in most cases, the purpose for which the commodity will be used.
- Description – includes a definition of the product or products covered with an indication, where appropriate, of the raw materials from which they are derived.
- Essential composition – includes information on the composition and identity characteristics of the commodity, as well as any compulsory and optional ingredients.

- Food additives – contains a reference to the General Standard on Food Additives and any specific provisions needed.
- Contaminants – contains a reference to the General Standard on Contaminants and Toxins in Food and Feed.
- Where appropriate, reference is also made to the Codex MRLs for pesticide residues and for residues of veterinary drugs in foods.
- Hygiene – makes reference to relevant Codex Codes of Hygienic Practice for the commodity concerned. In almost all cases, it is required that the product shall be free from pathogenic microorganisms or any toxins or other poisonous or deleterious substances in amounts that represent a hazard to health.
- Weights and measures – contains provisions such as fill of the container and the drained weight of the commodity.
- Labeling – includes provisions on the name of the food and any special requirements to ensure that the consumer is not deceived or misled about the nature of the food. These provisions must be consistent with the Codex General Standard for the Labeling of Prepackaged Foods. Requirements for the listing of ingredients and datemarking are specified.
- Methods of analysis and sampling – contains a list of the test methods needed to ensure that the commodity conforms to the requirements of the standard. References are made to internationally recognized test methods that meet the Commission's criteria for accuracy, precision, etc.

MRLs for residues of pesticides or veterinary drugs in foods are examples of numerical standards.

Codex general standards for food additives and contaminants and toxins in foods contain both general and numerical commodity-specific provisions.

The Codex General Standard for the Labeling of Prepackaged Foods covers all foods in this category.

Codex methods of analysis and sampling, including those for contaminants and residues of pesticides and veterinary drugs in foods, are also considered Codex standards.

Codex Guidelines

Principles that set out policy in certain key areas are:

- Addition of essential nutrients to foods.
- Food import and export inspection and certification.
- Establishment and application of microbiological criteria for foods.
- Conduct of microbiological risk assessment.
- Risk analysis of foods derived from modern biotechnology.

Interpretative Codex guidelines include those for food labeling, especially the regulation of claims made on the label. This group includes guidelines for nutrition and health claims; conditions for production, marketing, and labeling of organic foods; and foods that claim to be 'halal.' There are several guidelines that interpret the provisions of the Codex Principles for Food Import and Export Inspection and Certification, and guidelines on the conduct of safety assessments of foods from DNA-modified plants and microorganisms.

Codex Codes of Hygienic Practice

Codes of practice define the production, processing, manufacturing, transport, and storage practices for individual foods or groups of foods that are considered essential to ensure the safety and suitability of food for consumption. For food hygiene, the basic text is the Codex General Principles of Food Hygiene, which introduces the use of the Hazard Analysis and Critical Control Point food safety management system. A code of practice on the control of the use of veterinary drugs provides general guidance in this area. A series of codes of practice gives indications to producers on the prevention or reduction of specific contaminants in specific foods for example, aflatoxins in tree-nuts.

Science base of Codex and Risk Analysis

Science Base

The SPS Agreement requires that health and safety requirements for food should be based on sound scientific assessment of risk. In 1995, the Commission adopted four Statements of Principle Concerning the Role of Science in the Codex Decision-Making Process and the Extent to Which Other Factors are Taken into Account. These principles were supplemented by Statements of Principle Relating to the Role of Food Safety Risk Assessment (1997) and by Criteria for the Consideration of the Other Factors Referred to in the Second Statement of Principle (2001). The Comprehensive Working Principles for Risk Analysis in the Framework of the Codex Alimentarius was adopted by the Commission in 2003 and incorporated into the Procedural Manual of the Codex Alimentarius Commission.

Other Codex Committees (Additives, Contaminants, Hygiene, Pesticide residues, Nutrition, and Residues of Veterinary Drugs in Foods) have since then adopted specific risk analysis principles for their fields of activity that have also been included in the Procedural Manual.

Codex has also adopted Working Risk Analysis Principles for Food Safety for Application by Governments, which have been included in the Codex Alimentarius.

Risk analysis in Codex

Risk analysis in Codex follows a structured approach comprising the three distinct but closely linked components of risk analysis (risk assessment, risk management, and risk communication); each component being integral to the overall risk analysis.

The three components of risk analysis are documented fully and systematically in a transparent manner and effective communication and consultation with all interested parties is ensured throughout the risk analysis process.

There is a functional separation of risk assessment and risk management, in order to: Ensure the scientific integrity of the risk assessment; avoid confusion over the functions to be performed by risk assessors and risk managers; and reduce any conflict of interest. However, it is recognized that risk analysis is an iterative process, and interaction between

risk managers and risk assessors is essential for practical application.

Risk Assessment and Scientific Advice for Codex

The scientific advice for Codex is provided by expert bodies convened by WHO and FAO. These expert bodies are independent of the Codex Alimentarius Commission (and its subsidiary bodies) in order to ensure that the provision of scientific advice remains independent of the pragmatism that is required of risk management. The main principles of developing scientific advice are as follows.

- Excellence: Use of internationally recognized expertise, supported by the creation of a platform for global scientific discussions based on best practices in elaborating guidance.
- Independence: Experts contribute in their own capacity and not on behalf of a government or institution; they are required to declare possible conflicts of interest.
- Transparency: Procedures and methods to ensure that all interested parties understand the processes for the development of scientific advice and have access to the reports, safety assessments and evaluations, and other basic information.
- Universality: A broad base of scientific data is critical for the elaboration of international standards-setting activities. Therefore, institutions and all interested parties throughout the world are invited to make data available.

FAO/WHO Expert Bodies

The expert bodies currently providing scientific advice to Codex are as follows.

- The Joint FAO/WHO Expert Committee on Food Additives (JECFA).
- The Joint FAO/WHO Meetings on Pesticide Residues (JMPR).
- The Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment (JEMRA).
- An equivalent body for nutritional scientific advice (JEMNU) is under discussion.

JECFA and JMPR have been providing scientific assessments for more than 50 years. JEMRA began its work in 2000 and aims to optimize the use of microbiological risk assessment. In addition to providing scientific advice as basis for risk management decisions by Codex, the evaluations produced by these bodies are widely used by governments, industry, and research centers. These assessments contribute to the development of Codex standards, codes of practices, and other guidelines in the area of food safety. Ad hoc expert meetings to address specific topics that either require a rapid assessment or are outside the terms of reference of existing expert bodies are also organized by FAO and WHO.

Alternatives to Standards

When there is evidence that a risk to human health exists, but scientific data are insufficient or incomplete, the Codex Risk Analysis process provides that Codex should not proceed to elaborate a standard but should consider elaborating a related text, such as a code of practice, provided that such a text would be supported by the available scientific evidence.

Collaboration with Standard-Setting and Other Organizations

The Codex Alimentarius Commission works closely with the other standards-setting bodies mentioned in the SPS Agreement (OIE and IPPC) The Commission has strengthened collaboration with the standard setting activities of OIE relative to animal production food safety, in recognition that effective management of food safety risks demands a food chain approach from primary production to consumer. Codex and IPPC interact directly and inform each other through mutual participation in governing bodies.

FAO and WHO collaborate with other intergovernmental organizations to provide the best possible and most complete scientific advice. For example, the import_imagesInternational Atomic Energy Agency (IAEA) provides advice and support on levels of radionuclide contamination in foods and on food irradiation. The OIE provides advice on animal health, on animal diseases affecting humans, and on the linkages between animal health and food safety.

Ensuring Full and Effective Participation in Codex

Despite the importance of Codex in protecting health and facilitating trade, many countries have not been able to participate fully in the establishment of international food safety standards in Codex, mainly as a result of low income levels. To redress this situation, the Directors-General of FAO and WHO launched The FAO/WHO Project and Fund for Enhanced Participation in Codex (Codex Trust Fund) in 2003. The Codex Trust Fund is aimed at assisting developing countries and transition economy countries to enhance their level of effective participation in the Codex Alimentarius Commission. This is a vital step toward ensuring that the Codex system is inclusive, participatory, and equitable.

The Codex Trust Fund provides support to eligible countries to:

- Prepare for and participate in Codex Committees and related meetings;
- Participate in Codex training courses to enhance participation in Codex meetings;
- Prepare and present scientific/technical positions and data related to the work of Codex.

As of April 2011, 1418 participants from 139 countries have been supported to attend Codex meetings, task forces, and working groups, with the majority of support going to the least developed countries. A total of 336 participants from countries in all Codex regions had received Codex training to enhance their effective participation in Codex. This support was made possible with over US$ 11.7 million in contributions from 14 Codex Member States and 1 member organization.

FAO and WHO provide a range of capacity development activities aimed at ensuring that developing countries and transition economy countries participate effectively in Codex. Many of these training programs are based on an FAO/WHO training package for enhancing participation in Codex which is available on CD-ROM and the Internet.

The Codex Alimentarius Today and in the Future

Benefits of Codex for all Actors in the Food Supply Chain

Consumers

Today consumers enjoy a variety of food from all over the world. However, there is a risk that this food may be unsafe due to microbiological or chemical contaminants or additives, or may contribute to unhealthy diets due to nutrient content. The Codex Alimentarius rules for food labeling, food additives, pesticide residues, contaminants, food hygiene, and others provide a foundation for ensuring food safety and nutrient content of food. Therefore, consumers can be more confident about the safety and quality of the food they consume, regardless of its origin.

Food Exporters

The global market for trade in food continues to expand. In this growing and dynamic market, exporters need to be able to rely on a uniform and universally accepted set of standards such as those provided by the Codex Alimentarius. More and more countries participate actively in the standard-setting of the Commission and have adopted the standards on food production and processing, thereby facilitating food trade and contributing to the economic health of countries and regions around the world.

Food Producers

Food producers, including farmers and fishers, have a vital role in feeding the world. The Codex Alimentarius Commission assists them by developing standards that cover various types of food, including fats and oils, milk and milk products, fish and fishery products, and fruits and vegetables. Once producers meet these standards, they can be confident that their products are safe, of high quality, and are acceptable in export markets.

Developing Countries

FAO and WHO have capacity building programs to help developing countries comply with Codex Alimentarius standards and improve food quality and safety. Assistance includes helping countries to revise their food laws and regulations in accordance with Codex Alimentarius and strengthening their national food control systems (management, inspection, and laboratory services).

Keys to Success and Challenges

The keys to the success of Codex are that it is member driven, science based, transparent, inclusive, flexible, and based on consensus. This allows it to take on any new challenging issue brought up by a Member State.

The challenges facing Codex today include: The need to develop standards rapidly while remaining inclusive and transparent; finding consensus among members with different socioeconomic status and trade interest/needs; the need to increase the participation of developing countries and the increased use by businesses of private standards that may have different/stricter requirements than Codex standards.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Food and Agriculture Organization of the United Nations (FAO)

E Boutrif, Food and Agriculture Organization of the United Nations (FAO), Rome, Italy

Introduction

The Food and Agriculture Organization (FAO) is the principal United Nations' specialized agency whose mandate covers all aspects of food production, storage, transportation, processing, and marketing, and the development of agricultural and food-based programs to improve nutrition and enhance rural and national economies. Since its establishment in 1945, FAO has been leading the international community's effort to improve global food safety and quality through several major programs: (1) the provision of scientific advice to member governments, food industry, and consumers on food safety and quality; (2) the development of international food standards, guidelines, and recommendations; (3) the provision of policy and operational advice; (4) direct technical assistance to member countries in establishing or strengthening their national food control systems; (5) the emergency prevention system for food safety (EMPRES Food Safety), and (6) voluntary standards and schemes.

FAO's role in food safety and quality was further enhanced during the past decade through the emergence of the 'food chain' approach to food safety as the only effective way of ensuring the safety of the food supply at the global level. As a consequence, more attention is being given in FAO programs to food safety at different stages of the food chain, that is, primary production, storage, processing, distribution, etc. In addition to the central and longitudinal food safety work of the Food Quality and Standards Service, several units (animal production and health, plant production and protection, marine fisheries and aquaculture, food processing and marketing, and water for irrigation) have stepped up their work in food safety and quality assurance including the application of good practices.

FAO's Food Quality and Standards Service in FAO's Headquarters in Rome is the main central structure that deals with food safety matters. The Service benefits from the accumulated FAO technical and operational experience resulting from the interaction of normative and operational activities undertaken in cooperation with a wide variety of national and international partners at the global level. The Service also provides the Secretariat for the Joint FAO/World Health Organization (WHO) Food Standards Program (Codex Alimentarius). These facts, coupled with the interdisciplinary nature of FAO's work covering a wide range of policy and technical matters related to agricultural (including animal production and health) and fishery production ensure that quality and safety are considered throughout the food chain.

The technical assistance provided by the Food Quality and Standards Service also benefits from the extensive government and industry experience and expertise of its staff. The staff members have many years of experience in national and international food control programs and the food industry.

Provision of Scientific Advice

Risk Assessment: Scientific Basis of Food Safety Measures

FAO (jointly with WHO) promotes the application of risk assessment in all matters involving food safety. This must be based on sound scientific advice and evidence provided by panels of competent and independent experts. Risk assessment is one of the components of risk analysis – the other two being risk management and risk communication.

The Codex Alimentarius Commission (CAC) defines risk assessment as a scientifically based process consisting of the following four steps: (1) hazard identification; (2) hazard characterization; (3) exposure assessment; and (4) risk characterization. The risk assessment process is a means of providing an estimate of the probability and severity of illness attributable to a particular pathogen–commodity combination. The four-step process enables this to be carried out in a systematic manner, but the extent to which the steps are carried out will be dependent on the scope of the risk assessment. This can be defined clearly by the risk manager through ongoing dialog with the risk assessor.

Risk assessments provide information for identifying and characterizing food hazards. Risk assessment information is useful in determining which hazards are of such a nature that their prevention, elimination, or reduction to acceptable levels is necessary. The information is also useful in determining the most effective intervention strategies.

At present, there are two long-standing panels that provide advice to Codex, governments, and industry. They are the Joint FAO/WHO Expert Committee on Food Additives and Contaminants (JECFA) and Joint FAO/WHO Meeting on Pesticide Residues (JMPR). In addition, FAO and WHO convene ad hoc expert consultations whenever needed to address specific issues not covered by the permanent panels. In recent years, several expert consultations have been held on microbiological hazards in food, the risk assessment of foods derived from biotechnology and on animal feeding and food safety. FAO and WHO are currently studying the possibility of establishing an overall expert body on food safety risk

 doi:10.1016/B978-0-12-378612-8.00007-X

assessment that would oversee the entire work in this field and ensure the necessary link, synergy, and harmony between the specific expert panels and consultations.

JECFA

The JECFA is an international expert scientific committee that is administered jointly by FAO and WHO. It has been meeting since 1956, initially to evaluate the safety of food additives. Its work now includes the evaluation of contaminants, naturally occurring toxicants, and residues of veterinary drugs in food. To date, JECFA has evaluated more than 1300 food additives, approximately 25 contaminants and naturally occurring toxicants, and residues of approximately 80 veterinary drugs. The Committee has also developed principles for the safety assessment of chemicals in food that are consistent with current thinking on risk assessment and takes account of recent developments in toxicology and other relevant sciences. As of June 2001 the Committee had met a total of 57 times.

JECFA serves as a scientific advisory body to FAO, WHO, and their member governments, and to the CAC. Advice to the CAC on food additives, contaminants, and naturally occurring toxicants is normally provided via the Codex Committee on Food Additives and Contaminants (CCFAC) and advice on residues of veterinary drugs via the Codex Committee on Residues of Veterinary Drugs in Foods (CCRVDF).

All countries need to have access to reliable risk assessments of chemicals in food, but relatively few have the expertise and funds available to carry out separate risk assessments on large numbers of chemicals. JECFA performs a vital function in providing a reliable source of expert advice, and some countries use information from JECFA in formulating their own regulatory programs. In the same way, CCFAC and CCRVDF develop standards for chemicals in food based on JECFA evaluations.

For food additives, contaminants, and naturally occurring toxicants, the Committee does the following:

- elaborates principles for evaluating their safety;
- conducts toxicological evaluations and establishes acceptable daily intakes (ADIs) or tolerable intakes;
- prepares specifications of purity for food additives; and
- assesses intake.

For residues of veterinary drugs in food, the Committee does as follows:

- elaborates principles for evaluating their safety;
- establishes ADIs and recommends maximum residue limits (MRLs); and
- determines criteria for the appropriate methods of analysis for detecting and/or quantifying residues in food.

For food additives, JECFA normally establishes ADIs on the basis of available toxicological and other relevant information. Specifications of the identity and purity are also developed for food additives, which help to ensure that the product in commerce is of appropriate quality, can be manufactured consistently, and is equivalent to the material that was subjected to toxicological testing.

For contaminants and naturally occurring toxicants, levels corresponding to 'tolerable' intakes such as the provisional maximum tolerable daily intake or provisional tolerable weekly intake are normally established when there is an identifiable no-observed-effect level. When a no-observed-effect level cannot be identified the Committee may provide other advice depending on the circumstances.

In the case of veterinary drugs, data on good practice are evaluated and corresponding MRLs in animal tissues, milk, or eggs are recommended. Such MRLs are intended to provide assurance that when the drug has been used properly, the intake of residues of the drug present in food is unlikely to exceed the ADI.

More detailed information on JECFA's work can be found on the dedicated website, available on both FAO and WHO websites.

FAO/WHO JMPR

The JMPR is comprised of the Joint Meeting of the FAO Panel of Experts on Pesticide Residues in Food and in the Environment and the WHO Core Assessment Group. JMPR carries out toxicological evaluation of pesticide residues, normally resulting in an estimate of the ADI. In addition, JMPR proposes MRLs for individual pesticides in or on specific commodities. These MRLs are primarily based on the residue levels estimated in supervised field trials when the pesticide is used according to good agricultural practices (GAPs). In cases where initial estimates indicate that the ADI may be exceeded, more refined intake calculations are performed using national food consumption data and information from pesticide residues monitoring programs.

These Expert Committees establish chemical safety standards based on a review of toxicological studies in the more sensitive test animal species. They factor in an adequate level of safety, use risk assessment procedures, consider use and consumption patterns, and define the specifications of the identity and purity of food grade chemicals to be used.

Microbiological Risk Assessment

Since 1999, and at the request of the CAC, FAO and WHO have initiated a series of joint expert consultations to assess risk associated with microbiological contamination of foods (Joint FAO/WHO Expert meetings on Microbiological Risk Assessment). This followed the adoption by the CAC of the Principles and Guidelines for the Conduct of Microbiological Risk Assessment (MRA).

The aim of these joint expert consultations is to provide a transparent review of scientific data on the state of the art of MRA, and to develop the means of achieving sound quantitative risk assessments of specific pathogen–commodity combinations. The work includes an evaluation of existing risk assessments; a review of the available data and current risk assessment methodologies, highlighting their strengths and weaknesses and how they may be applied; provision of examples; and identification of data and information needs/GAPs. A further aim of these consultations is the development of guidelines relating to the different steps of risk assessment,

such as hazard characterization and exposure assessment. The purpose of such guidelines is to help the risk assessor, the risk manager, and other interested parties to understand the principles and science behind the risk assessment steps.

A series of such consultations has already been organized. They have dealt with the risk assessment of *Salmonella* spp. in broilers, *Salmonella* Enteritidis in eggs, *Listeria monocytogenes* in ready-to-eat foods, *Campylobacter* in broiler chickens, and *Vibrio* spp. in seafood. The work plan and priorities for MRA are established in close collaboration with the Codex Committee on Food Hygiene.

Ad hoc expert advice: FAO frequently carries out expert consultations and meetings, often jointly with the WHO, on a range of issues related to quality and safety of foods. Examples include the FAO Technical Consultation on Food Allergies, the Joint FAO/WHO Consultation on Biotechnology and Food Safety, the Joint FAO/WHO Consultation on Food Safety Risk Management, the FAO Expert Consultation on Animal Feeding and Food Safety, and the FAO/WHO Expert Consultation on Nanotechnology and Food Safety.

Example of Ad hoc Expert Advice: Genetically Modified (GM) Food Safety Risk Assessment

The use of modern biotechnology for the genetic modification of plants, microorganisms, and animals for the production and processing of foods poses additional concerns to certain consumer groups. FAO recognizes that modern biotechnologies have potential to raise agricultural productivity, reduce dependence on harmful chemicals, and increase the nutritional value of foods. However, FAO also acknowledges that there are possible risks to human and animal health and to the environment, which require a case-by-case assessment.

FAO, jointly with WHO, organized a series of expert consultations to consider general safety and nutritional aspects of foods derived from modern biotechnology. The consultations addressed 'Strategies for assessing the safety of foods produced by biotechnology' in 1990, 'Biotechnology and food safety' in 1996, and 'Safety aspects of genetically modified foods of plant origin' in 2000 and 2001. The latter consultations addressed questions specifically on safety that were raised by Codex Intergovernmental ad hoc Task Force on Foods derived from Biotechnology. The 2000 Consultation reframed the concept of substantial equivalence and identified a set of priority issues that are to be addressed in future FAO and WHO consultations. The 2001 consultation revised the international guidelines on the assessment of potential allergenicity of novel recombinant proteins to address broader concerns or critics of the previous approach. A second consultation in 2001 was convened to consider the criteria essential for the risk assessment of food and food ingredients produced with the aid of or containing viable or nonviable GM microorganisms.

The recommendations of Joint FAO/WHO expert committees and ad hoc consultations provide valuable guidance to member countries and also form the basis for intergovernmental discussions within the CAC. The resulting Codex standards, guidelines, and recommendations provide the basis for harmonization of national food safety regulations.

Development of International Food Standards, Guidelines, and Recommendations (Codex Alimentarius)

FAO and WHO are cofounders of the Codex Almentarius Commission, an intergovernmental body entrusted by the FAO Conference (1962) and the WHO World Health Assembly (1963) to develop international food standards, guidelines, and recommendations with the double objective of protecting consumer's health and ensuring fair practices in food trade. FAO hosts the Secretariat of the CAC and provides the necessary technical and administrative support for its smooth running. More details on the role of the FAO/WHO Codex Alimentarius Commission in food safety is provided elsewhere in this encyclopedia.

Provision of Policy and Operational Advice

FAO provides policy orientation and advice on the organization, management, and operation of national food safety and control systems. This is provided either directly to member countries on request, or indirectly through FAO's authoritative publications and reports. Examples of such work include:

- *Food contamination and residues monitoring*: Food contamination by chemical and biological agents continues to be a serious problem around the world. Surveillance and monitoring of contaminants (chemical and biological) in foods is therefore important not only for the protection of public health but also because of its negative economic impact. Excessive levels of aflatoxin or pesticide residues in food raise consumer's concern about their health implications, and are often a cause of food import rejections in international food trade. FAO advises member countries on the establishment and operation of national food contamination monitoring programs to allow a continuous assessment of the food safety situation at national level and enable food safety authorities to take timely, corrective measures whenever a food safety problem is identified. FAO also assists in the analysis of the causes of the contamination problems and in formulating and implementing preventive actions.
- *Food control management, inspection, analysis, and quality control*: Adherence to Codex standards, guidelines, and recommendations and achieving the appropriate level of sanitary and phytosanitary protection related to food safety can only be assured by establishing effective national food control systems. Therefore, technical assistance provided by FAO is directed toward establishing or strengthening the necessary elements of such systems. FAO's technical assistance aims at creating the political will for, and technical understanding of, these elements to enable proper institutional building process.

FAO provides expert advice required for the development and operation of effective national food control systems including food inspection and sampling programs. Advice is also given on food laboratory management and on accurate, reliable, and cost-effective methods of analysis. Organizing

simple but effective systems of food quality control based on the Codex General Principles of Food Hygiene throughout the food chain improves food quality and safety, reduces food losses, and facilitates international food trade.

FAO's manuals and tools related to food safety and quality provide practical guidance for the development and operation of food quality and safety systems. These are aimed primarily at providing advice to developing countries, and document modern approaches for the development and implementation of risk-based food safety programs throughout the food chain. Such an approach is instrumental in facilitating international trade in food. Key titles in the series include: Food Safety Risk Analysis – A Guide for National Food Safety Authorities (2006), Assuring Food Safety and Quality: Guidelines for Strengthening National Food Control Systems (2003), Manual on the Application of the HACCP System in Mycotoxin Prevention and Control (2001), Animal Feeding and Food Safet, (1998), Imported Food Inspection (1993), and Management of Food Control Programmes (1991).

Direct Technical Assistance to Developing Countries

Direct technical assistance, in the form of project formulation, implementation, consultation, training, and/or other advisory services, is provided, at their request, to many developing countries and countries in transitional economies through the FAO Technical Cooperation Program or through other financing sources (FAO/Government Cooperation Program, Trust Fund arrangement; UNDP, and others). The trade in food is, for many countries, a prime source of foreign exchange. The challenge is to meet the appropriate level of sanitary and phytosanitary protection of importing countries. This requires the establishment of effective export food control systems that provide assurance of adherence to Codex/importing country's standards, guidelines, and recommendations by the exporting country. FAO technical assistance is provided to countries in developing effective food import and export controls thereby increasing confidence in the countries' food products and reducing the number of shipments rejected by importing countries. The Codex Committee on Food Import and Export Inspection Certification Systems provides valuable advice and recommendations in this area.

The following are some highlights of a few of these activities that are being carried out at present and which provide a general idea of FAO's work, which is carried out to meet general or specific food control requests from developing countries.

- *Development of national strategies*: Developing an effective national strategy on food quality control and safety should take into account the development needs of the country and contribute to national development programmes, particularly those related to food security. To provide coherence in national food control strategies, FAO assists member countries in reviewing their food control strategies and infrastructure, usually by convening national workshops involving all those directly and indirectly concerned with food safety and quality. More than 100 such workshops or reviews have been held in developing countries, with the participation of Ministries of Agriculture, Health, Commerce, and/or Industry, as appropriate to the existing infrastructure, as well representatives of the industry, consumers, and other interested parties. Weaknesses and strengths are identified and measures are proposed to strengthen the national infrastructure, often with the help of FAO-executed projects.
- *Advice on food legislation*: FAO assists countries in the review and updating of their national food legislation so as to take into account recent developments, including the World Trade Organization Agreements on Sanitary and Phytosanitary Standards (SPS) and Technical Barriers to Trade (TBT). The Model Food Law developed jointly by FAO and WHO and the Codex Alimentarius standards, guidelines, and recommendations constitute unique references in the development and harmonization of food legislation worldwide.
- *Training and manpower development*: Training of governmental and food industry personnel in all aspects of food quality and safety is a major aspect of FAO technical assistance and capacity development work. Emphasis is placed on food inspection, food analysis, certification requirements and procedures for export, application of HACCP systems in food processing and handling establishment, effective participation in Codex standard setting process, food safety management programs at various levels. These training activities are carried out as part of Regular Program activities or under FAO-executed projects.
- *Export and international trade*: Special emphasis continues to be given to improving national export food inspection and certification programs so that exporting countries have confidence that their products are acceptable to import authorities. Projects dealing specifically with this matter have been implemented in many countries including countries with emerging economies.

National and regional workshops on export food control have been organized for many countries to assess the existing situation and develop strategies and actions for the future.

EMPRES Food Safety

The FAO EMPRES Food Safety contributes to global effort for the prevention and control of food safety risks with the double aim of improving food security and protecting public health. EMPRES Food Safety complements and enhances FAO's ongoing work in animal and plant health emergencies. It serves FAO member countries through the three pillars of early warning, emergency prevention, and rapid response.

Early warning is provided through the FAO/WHO International Food Safety Authorities Network operated by WHO. It involves activities in incident scanning, identification, and verification. EMPRES Food Safety is developing an international network to gather information and intelligence data to conduct horizon scanning, involving other FAO units and decentralized offices, other UN agencies, national and regional governmental bodies, universities, research institutes, and related groups.

FAO, in collaboration with WHO, has developed a series of technical tools that provide countries with practical

guidance on food safety emergencies and reinforce emergency preparedness.

In case of a food safety incident, EMPRES Food Safety works with national food safety authorities to conduct an urgent appraisal of the event and mobilize the needed experts. Wherever needed, the input of experts in public health is sought through WHO. Together with national food safety authorities, EMPRES Food Safety determines the best possible emergency response, and assists in its implementation.

Voluntary Standards and Schemes

In recent years, there has been growing consumer interest for food and agricultural products that have specific characteristics regarding the final product or production system. This has led to the development of a number of voluntary standards, certification systems, labels, and regulatory instruments that relate to factors such as preservation of environment, social welfare and equity, traditions and geographical origin, nutritional aspects, etc. FAO's work on voluntary standards and schemes aims at providing the necessary support to relevant institutions value chain actors in interested countries, in setting up and implementing voluntary standards and schemes, taking into account their needs and constraints as well as the international regulatory framework and standards.

INSTITUTIONS INVOLVED IN FOOD SAFETY

World Health Organization (WHO)

J Schlundt, Technical University of Denmark, Copenhagen, Denmark

Glossary

Hazard A biological, chemical, or physical agent in or property of food that may have an adverse health effect.
Risk A function of the probability of an adverse effect and the magnitude of that effect, consequential to a hazard in food.
Risk analysis Formalized process to assess, manage and communicate risk.
Risk assessment Scientific formalized process to estimate risk and its attendant uncertainties.
Risk communication An interactive process of exchange of information and opinion on risk among risk assessors, risk managers and other interested parties.
Risk management The process of weighing policy alternatives to accept, minimize or reduce assessed risk and to select and implement appropriate options.

Food Safety as a Health Issue

Foodborne disease (FBD) continues to be a major public health issue. Food safety and FBDs have implications both on the health of individuals and the development of societies. Concerned by this, the Sixty-Third World Health Assembly (WHA), the governing body of the World Health Organization (WHO), in May 2010 reminded the Director-General of WHO of the need for efficient gathering and exchange of information in and among countries; and adopted a resolution 'Advancing Food Safety Initiatives (WHO, 2010).' The resolution asked Member States to establish disease burden estimation and surveillance and to contribute to the timely conduct of international risk assessments through the provision of relevant data and expertise. And specifically the resolution called upon the Director-General of WHO to help countries build relevant capacity to improve cross-sectoral collaboration along the whole food production chain and to establish with the International Food Safety Authorities Network (INFOSAN) an international initiative for the collaboration of laboratory partners in support of surveillance of FBD, identification of food contamination, and emergency response, including outbreak investigation.

WHO's Role in the Conceptual Development of Food Safety

WHO's central role in food safety as well as in other public health areas is a normative one and includes the facilitation of risk assessment and international standard setting. The most thorough normative change over the past decades in the food safety area has been the introduction of a formalized system to prepare and utilize science-based risk assessments to improve the safety of food, both at international and national level. For almost 20 years, WHO has promoted the new concept of risk analysis as a framework for the management of food production and food safety. Developed by WHO in collaboration with the Food and Agricultural Organization of the United Nations (FAO), the risk analysis framework and principles are depicted in Figure 1. Within this framework it is important to achieve functional separation of risk assessment (the science) and risk management (the intervention). The final goal of assessment should be to inform risk managers and other stakeholders of the nature, occurrence, and size of the risk in order to improve the quality of risk management decisions.

New concepts were needed because the old food safety systems have failed in the sense that the incidence of FBDs seems to have increased over the past decades in most countries. One of the reasons for this has been the intuitive reliance on testing. It must be realized that safety cannot be achieved by monitoring the presence of pathogens in the end product because it is impossible to test sufficient samples to obtain the necessary degree of statistical power to detect all contaminants at levels that may create unacceptable health risks. Therefore, a proactive approach is required, starting with the producer, including in many cases the primary production sector, ensuring a safe product based on predictive risk assessment and, where relevant, implementation of action plans to lower the prevalence of relevant pathogens.

The main focus of WHO's work in the area has been the development of methods for quantitative microbiological and chemical risk assessment, FBD surveillance, and also the assessment of the safety of new products used in food, including genetically modified (GM) foods. The use of risk assessment to improve risk management decisions and risk communication to enable transparent and proactive interaction between all interested parties, constitute the two other components of the risk analysis framework.

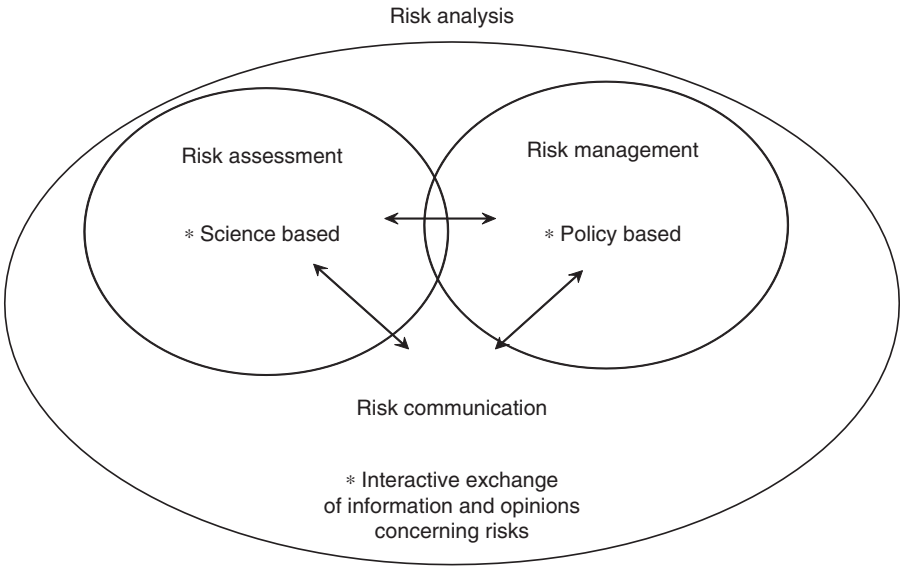

Figure 1 The WHO/FAO risk analysis paradigm, with risk assessment independent from undue influence from risk managers, and with everything floating in a sea of risk communication.

The Structure of WHO Relative to Food Safety Work

WHO's food safety activities extend from the WHO headquarters (HQ) in Geneva, Switzerland, often through six Regional Offices: AMRO (Regional Office for the Americas), AFRO (Regional Office for Africa), EMRO (Regional Office for the Eastern Mediterranean), EURO (Regional Office for Europe), SEARO (Regional Office for South-East Asia) and WPRO (Regional Office for the Western Pacific). The regional structure of WHO stems historically from the creation of WHO in 1948, where the preexisting Pan-American Health Organization was included in WHO as AMRO with an existing, independent governance structure. This independent structure was replicated in the other five regional offices, thereby creating an organization with not one, but seven politically appointed heads. In effect this means that each Regional Director is independently elected, and thus in effect can define policy course on his or her own. The regional offices receive approximately 75% of the WHO's budget and because regional directors are not appointed by or formally responsible to the WHO's Director-General, criticism has been voiced that some of the agency's activities are uncoordinated and not based on the best scientific evidence.

Over the later years, WHO has seen significant cuts in its budget. Therefore, a number of technical departments in the WHO HQ have seen cuts in technical staff. But even before these cuts the technical area of food safety was small in the WHO HQ as well as in regions. At its peak in 2008, the Department for Food Safety and Zoonoses at the WHO HQ included approximately 12–14 scientific staff and 6–8 other staff, whereas the regional offices typically had less than 1 scientific staff in this area. At the third layer of the organization, the country offices, food safety is typically covered by staff, who also cover a number of other technical areas. Nevertheless, the WHO has been able to support significant development in national food safety programs, and shoulder a very significant work load in the area, primarily through the active support of – mostly nationally funded – scientists from all over the world.

Most of the WHO work in the food safety area is conducted in some sort of collaboration with FAO. In the 1990s, the collaborative efforts between the two organizations were somewhat hampered by policy disagreement and to some degree by personal fights between WHO and FAO staff, including staff at senior level. Under the administration of WHO Director-General Dr Gro Harlem Brundtland, WHO in the late 1990s introduced the 'farm-to-fork' collaborative line with FAO, a policy line mirrored by FAO. This did not mean that the two organizations necessarily agreed in all policy areas, but a cooperative effort was underlined in most areas of work. Following the major zoonotic outbreaks in the first decade of 2000, including severe acute respiratory syndrome (SARS), avian influenza, and type H1N1 influenza, the collaboration between FAO and WHO was extended to also include the World Animal Health Organisation (OIE).

Scientific Advice

The collaborative efforts between WHO and FAO in the area of provision of scientific advice include three expert groups with relatively regular meetings. These groups are managed differently, but all in collaboration between WHO and FAO. They are the Joint FAO/WHO Expert Committee on Food Additives and Contaminants (JECFA), the Joint FAO/WHO Meeting on Pesticide Residues (JMPR), and the Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment (JEMRA). For further description of the work of these joint committees, see the article on FAO, or visit:

1. http://www.who.int/foodsafety/chem/jecfa/publications/en/index.html (JECFA).

2. http://www.who.int/foodsafety/chem/jmpr/publications/en/index.html (JMPR).
3. http://www.who.int/foodsafety/micro/jemra/en/ (JEMRA).

In addition to these expert groups, FAO and WHO have hosted a number of ad hoc expert meetings in relation to food safety issues. An example of such an ad hoc expert meeting is the Ad hoc Expert Group on Food Safety Risk Assessment of GM Food, which is described in an other article.

Providing Scientific Advice That Has Not Been Asked For

Whereas the expert groups described above all typically respond to specific requests for scientific advice, in most cases from the FAO/WHO Codex Alimentarius Commission (CAC), WHO has in a number of cases initiated scientific work without such request. The examples are manifold, but three important examples shall be briefly described here.

1. Antimicrobial resistance (AMR) is a global public health issue that is impacted by both human and nonhuman antimicrobial usage. The continuing emergence, development, and spread of pathogenic microorganisms that are resistant to antimicrobials are a cause of increasing concern. WHO's involvement in the containment of AMR due to nonhuman antimicrobial usage dates back to the late 1990s, and includes the hosting of a number of expert meetings from 1997 to this day. Although the other relevant international organizations in this area – FAO and OIE – were not immediately supportive of the suggestions coming out of these expert meetings, through continued efforts from WHO the issue has since 2007 also been included in CAC work. These efforts have led to clear recommendations about prudent use of antimicrobials in animals as well as a description and selection of critically important antimicrobials. Whereas some recommendations have been implemented in some parts of the world, a very significant number of recommendations have not. In most countries, antimicrobials are still used as growth promoters, and veterinarians are still allowed to make profits from selling such drugs.
2. Acrylamide was until 2002 considered an occupational health issue only, as this substance had not been found in food. Therefore, it was considered dramatic news when Swedish researchers in March 2002 unveiled research showing very high concentrations of acrylamide in ordinary food items, such as French fries, bread, and coffee. Although some experts dismissed the importance of these findings – for example, with statements about how 'we have eaten these types of food for centuries' – WHO maintained a serious attitude toward these findings relative to a substance that had been proven carcinogenic in animals. Thus, a WHO/FAO expert consultation was undertaken less than 2 months after the Swedish news. The consultation considered that the available data suggested that toxicological findings in animals should be assumed to be relevant for extrapolation to humans. The consultation also provided a range of recommendations for further information and new studies to better understand the risk to human health posed by acrylamide in food.
3. In September 2008, the INFOSAN Emergency Surveillance System obtained information from the Chinese Ministry of Health (MoH) that a serious and widespread contamination event had occurred in China. The contamination of infant formula with melamine had been spurred by fraudulent use of melamine to disguise the dilution of milk with water. Through further interaction between INFOSAN and MoH the issue of potential other use of the contaminated milk powder as well as parallel (illegal) distribution of contaminated milk powder to other countries was investigated. An INFOSAN Emergency Alert was distributed to the network and subsequently updates were issued regularly during the following months. A WHO Expert Meeting was held in collaboration with FAO a few months after the event unfolded in an effort to elucidate the normal ('baseline') exposure of humans to melamine, as well as suggest relevant tolerable daily intakes of melamine through food.

International Standards and Guidelines

People in ancient times already understood they could get sick from consumption of infected meat, and that keeping their animals healthy and using dedicated methods of food preparation and conservation could improve their health. Maybe the oldest written document about this, 'On Airs, Waters, and Places' is by Hippocrates that describes how human health is influenced by its interaction with the environment. A clear understanding of the importance of food and food safety for health led to the creation of the FAO/WHO Food Standards Programme in 1963, the active arm of which is the FAO/WHO the CAC. The CAC now meets once a year and agrees on food standards, guidelines, and codes of practice, typically developed in one of its 16 committees and task forces. However, the CAC system had become a very heavy system with significant bureaucracy. Realizing this, WHO and FAO in 2001 initiated an evaluation, resulting in some, but not very profound changes, including a higher level of inclusiveness especially toward developing countries. However, the system has also proven a capacity to move fast, even when dealing with politically charged issues. For example, the development of guidelines for the assessment of GM foods was finalized within a time period of only 4 years. When considering that such standards are developed based on several FAO/WHO expert meetings, as well as several task force meetings, many times with the participation of 50–70 countries, this is actually an impressive international achievement.

Because the work of CAC is governed by the member countries, the system typically does not deal immediately with new or upcoming issues, unless key member countries take a direct interest in this. An example of an important food safety issue that has only been taken up reluctantly by CAC is the problem of AMR in microorganisms. Later in this article, forward-looking initiatives by the WHO in this area will be described, but it is noteworthy that it was only in 2007 that

CAC agreed to start an initiative in this area, i.e., the Codex AMR Task Force.

Although CAC standards and guidelines are in effect just voluntary guidance documents, the specific reference to CAC in the World Trade Organization agreements as the 'gold standard' in the food safety area has meant that most countries take CAC guidance seriously. Nevertheless, CAC standards and guidelines have no legal status above this. However, WHO has an international legal instrument that covers certain aspects of food safety, the International Health Regulations (IHR), which is a legally binding agreement for all 194 Member States of the Organization. The aim of these regulations is to help the international community prevent and respond to acute public health emergencies that have the potential to cross borders and threaten people worldwide. Such public health emergencies include risks related to food, because diseases can spread far and wide via international food trade. A health crisis in one country can impact the health, livelihoods, and economies in many parts of the world. The IHR aims to reduce unwarranted interference with international traffic and trade, while ensuring public health through the prevention of disease spread.

The present IHR, which entered into force on 15 June 2007, require countries to report certain disease outbreaks and public health events to WHO. Building on the unique experience of WHO in global disease surveillance, alert, and response, the IHR defines the rights and obligations of countries to report public health events, and establish a number of procedures that WHO must follow in its work to uphold global public health security. Thus, countries have an obligation to inform the global community, through WHO, about any public health risk related to food, which has the potential to cross borders or that are otherwise unique. WHO has created a specific system for the reporting of such food safety events: The INFOSAN, which operates in collaboration with FAO, is described in this article under the section 'Food Safety Emergency Action and Exchange of Experience over Borders.'

FBD Burden

Although important parts of international food safety work involves the collaborative WHO–FAO framework, a number of issues related more specifically to the occurrence, surveillance, and prevention of FBD are primarily supported at the international level by WHO. FBDs result from the ingestion of contaminated foods and food products and include a broad group of illnesses caused by biological and chemical agents, which contaminate food at different points in the food production and preparation process. In work sponsored by the WHO FBD Burden Epidemiology Reference Group (FERG), it was estimated that in 2008, 1.336 million children under the age of 5 years die every year from diarrhea caused by contaminated food or water. Consequently, diarrhea is the second leading cause of death among children after respiratory diseases. In 2009, another FERG-sponsored study estimated that diarrhea-related deaths among adolescents and adults were 1.15 million per year. The total mortality of 2.486 million deaths due to diarrhea is more than deaths due to AIDS, malaria, and measles combined.

As usual the poorest part of the population is at the highest risk: In general, malnutrition can result in a 30 fold increase in the risk for diarrhea-associated death. When considering these estimates of child deaths, it is important to realize that they do not include deaths in other age groups, deaths as caused by foodborne microorganisms not resulting in diarrhea nor the probably very significant disease burden caused by chemical substances, including naturally occurring chemical substances in food. Such chemical substances include aflatoxins caused by fungi growing in food as a result of poor storage conditions, or acrylamide formed in certain foods when heated $>120^{\circ}$C.

Although most diarrheal deaths occur in poor countries, FBDs are not limited to developing countries. It is estimated that, in 2011 in the USA, FBDs resulted in 48 million illnesses (one in six people), 128 000 hospitalizations, and 3000 deaths per year resulting in medical costs and productivity losses in the US$ billions. The full extent of the burden and cost of unsafe food is currently still unknown, but its impact on global health security, trade, and development is considered to be profound. Thus, valid estimations of the real FBD burden are basically nonexistent. Recognizing the current data gap, WHO has launched an Initiative to Estimate the Global Burden of FBDs from all major causes using summary health metrics that combine morbidity, mortality, and disability in the form of the disability-adjusted life year. This has been initiated through the establishment of the FBD Burden Epidemiology Reference Group (FERG). The FERG members are mandated to engage in assembling, appraising, and reporting on currently existing burden of FBD estimates, conducting epidemiological reviews for mortality, morbidity, and disability in each of the major FBD, providing models for the estimation of FBD burden where data are lacking, developing source attribution models to estimate the proportion of diseases that are foodborne, and developing user-friendly tools for burden of FBD studies at country level. Although the work of FERG was originally stipulated to result in (some) global FBD data by 2012, the work is still ongoing, and parts of the work seem hampered by recent funding trouble.

Food Safety Emergency Action and Exchange of Experience over Borders

In 2000, the Fifty-Third WHA recognized the serious threat to public health posed by foodborne illness and called for improved 'gathering and exchange of information in and between countries and regions on matters of food safety'. The Fifty-Fifth WHA in 2002 expressed serious concerns about health emergencies posed by natural, accidental, and intentional contamination, including food contamination, and requested WHO to coordinate the identification of and response to such emergencies.

In 2004, in response to the aforementioned resolutions and in reply to a specific request made by the FAO/WHO CAC, WHO established the INFOSAN, in collaboration with FAO. The network was built to help Member States deal with international food safety incidents and emergencies, and to facilitate communication and information sharing among all food safety stakeholders. Currently, 167 Member States are members of INFOSAN.

The INFOSAN network not only responds to the reporting of human FBD cases to WHO, but also provides information to countries when a food contamination event has the potential to affect human or animal health at a later stage. To promote seamless action throughout the food chain continuum, INFOSAN and the Global Early Warning System (GLEWS) for Major Animal Diseases, including Zoonoses exchange information directly. GLEWS is a confidential early warning network of WHO, FAO, and OIE used to track, verify, and analyze transboundary zoonotic diseases. This network brings together the expertise of the three different organizations to maximize prevention and control of zoonotic diseases. INFOSAN and GLEWS coordinate efforts relative to food safety events linked to animal health (e.g., avian influenza), animal feed (e.g., aflatoxin), or farm practices (e.g., AMR).

In addition to emergency information, INFOSAN facilitates the exchange of food safety information and experience among its members through the publication of INFOSAN Information Notes, in the six official WHO languages. These Notes provide INFOSAN members with summaries on relevant food safety issues. This INFOSAN function is supplemented with capacity building efforts aimed at the building of integrated food safety systems able to manage and monitor events with national or international implications.

Data and Laboratory Networks

WHO has for a number of years hosted the first ever global database for food contamination, focused on chemical contaminants. The Global Environment Monitoring System–Food Contamination Monitoring and Assessment Program (GEMS/Food) was established in 1976 to inform national governments, CAC, and other stakeholders, as well as the public, on levels and trends of chemical contaminants in food and their contribution to dietary exposure. The program operates through a network of WHO Collaborating Centers and national institutions located in approximately 70 countries around the world. National data are submitted to GEMS/Food to conduct international scientific assessments of exposure, as part of chemical risk assessment. In addition, WHO has developed an approach to describe the various diets around the world. The GEMS/Food Consumption Cluster Diets were updated in 2006 and are now used both nationally and internationally for exposure assessment of food contaminants and pesticide residues (Figure 2: WHO GEMS/Food Consumption Cluster Diets).

Recognizing an urgent need for building Member State capacity in surveillance of foodborne and other enteric infections from the farm to the table, the WHO in 2000 initiated the WHO Global Salm-Surv, now called Global Foodborne Infections Network (GFN). The network promotes integrated, laboratory-based surveillance, and fosters intersectoral collaboration and communication among microbiologists and epidemiologists in human health, veterinary, and food-related disciplines. The network has been created with the support of some of the most respected national laboratories in these areas from a long list of WHO Member States, including Australia, Canada, Denmark, France, Germany, Japan, Netherlands and the USA.

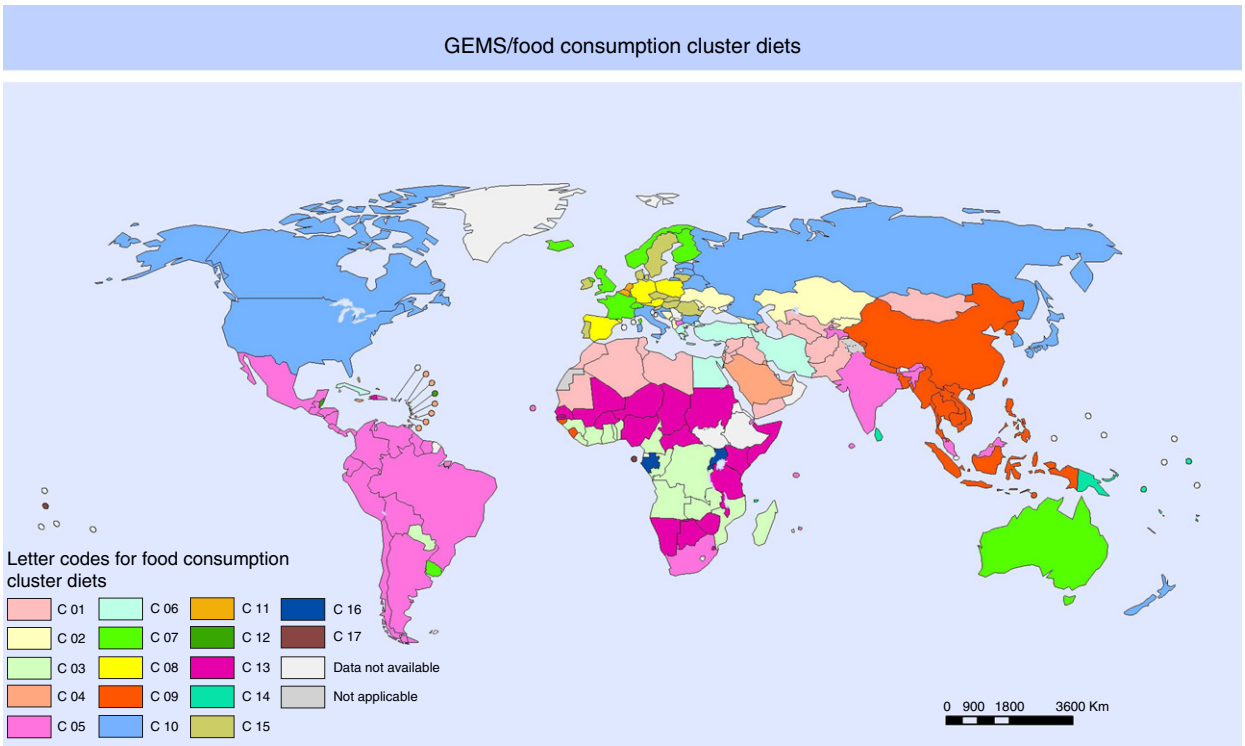

Figure 2 WHO GEMS/Food consumption cluster diets. Reproduced from http://www.who.int/foodsafety/chem/Global_GEMS_CLUSTERS_2012.jpg.

By May 2012 the GFN included 1062 members from 184 Member States, and continuous activities covering: regional training courses on FBD surveillance, risk assessment and epidemiology, external quality assurance programs on microbiology, reference testing of selected foodborne pathogens, and provision of technical information and methodological support for microbiological laboratories. The GFN also hosts a country data bank with data on national *Salmonella* isolates from more than 83 countries comprising approximately 1.5 million human and 360 000 nonhuman isolates.

WHO considers new activities linking databases covering microbiological and chemical contaminants in food in an effort to promote the sharing of food contamination data among countries.

The Future of Food Safety and WHO's Role – Promoting Safer Food and Better Health

The future food safety systems will most likely enable new ways of evaluating disease metrics and attribute such disease directly to food groups. It is likely that new genetic fingerprinting techniques will enable attribution for all pathogenic microorganisms related to food, and new chemical fingerprinting (metabolomics) will enable a significantly better understanding of the effect of chemicals in food. At the same time the new line of risk-based approaches will enable the setting of national – and international – targets for disease reduction, as well as provide the evidence base for such reduction efforts. These approaches will make their way into all parts of the global market, including the developing countries, which are likely to become more and more important agricultural producers and exporters. The introduction of a risk-based framework will enable developing countries to learn from mistakes (and successes) elsewhere. These countries have the potential to 'leap forward' into preventative systems focusing on risks. In addition, at a time where trade restrictions and national/regional protection of the agricultural production through heavy subsidies is likely to come to an end, it will be of paramount importance for the production sector also in developing countries to adapt to the new times. The benefits of improving food safety amount to a 'win-win' situation with improved national health as well as improved export potential. However, it will be crucial for these potential future developments that the developments in new food safety systems is clearly documented and communicated. Such communication has not yet commenced; national authorities as well as international organizations have an important future task in this area.

In supporting such developments, the WHO should focus on its core business. WHO is neither a funding agency nor an implementing agency like United Nations Children's Fund (UNICEF). Instead, it should aim to be the paramount knowledge organization in global health – gathering up the best technical, scientific, and practical information and making it accessible to all countries. This does not mean that WHO products must necessarily only be theoretical analyses aimed at scientific debate. A very significant amount of WHO documentation is directly applicable in national food safety efforts. The information material about GM food ('20 Questions on GM Food'), the exchange of national experience in risk mitigation activities through INFOSAN, or indeed the global spread of the simple WHO message on safe food handling ('Five Keys to Safer Food') all are clear testament to the fact that if the core remains sound science, the application of practical support to countries can take many forms.

WHO should continue to take bold action in support of continuous improvement of national and global food safety. This also means that WHO must remain an impartial and independent broker of sound science. Only thus can WHO contribute to a better – and safer – future for the world.

INSTITUTIONS INVOLVED IN FOOD SAFETY

World Organisation for Animal Health (OIE)

M Thibier and B Vallat, World Organisation for Animal Health, Paris, France

Glossary

Antimicrobial resistance The resistance of a microorganism to an antimicrobial medicine to which it was previously sensitive. Resistant organisms include bacteria, viruses, and some parasites. The World Organisation for Animal Health (OIE) recognizes that antimicrobial resistance is a global public and animal health concern that is influenced by the usage of antimicrobial agents in humans, animals, and elsewhere. Those working in the human, animal, and plant sectors have a shared responsibility to prevent or minimize pressures for the selection of antimicrobial resistance factors in humans and animals.

Emerging diseases A new infection resulting from the evolution or change of an existing pathogenic agent, a known infection spreading to a new geographic area or population, or a previously unrecognized pathogenic agent or disease diagnosed for the first time and which has a significant impact on animal or public health.

Food safety A scientific discipline describing handling, preparation, processing, and storage of food in ways that prevent foodborne illness. This includes a number of routines that should give assurance that food will not cause harm to the consumer when it is prepared or eaten according to its intended use.

Foodborne hazards A biologic, chemical, or physical agent in, or a condition of, food such as an animal product with the potential to cause an adverse health effect (OIE). Biologic hazards can be posed by parasites, viruses, or bacteria. Chemical contaminants in foods can come from industrial and agricultural sources, from food processing, or from the food itself. Toxic chemicals also come from biological sources such as molds and algae. Foreign objects present in food could constitute a physical hazard to the consumer.

Foodborne illness Also called as foodborne disease and colloquially referred to as food poisoning resulting from the consumption of contaminated food, pathogenic bacteria, viruses, or parasites that contaminate food, as well as chemical or natural toxins such as poisonous mushrooms.

Veterinary Services The governmental and nongovernmental organizations that implement animal health and 'welfare' measures and other standards and recommendations in the Terrestrial Code and the OIE Aquatic Animal Health Code in the territory. The Veterinary Services are under the overall control and direction of the Veterinary Authority. Private sector organizations, 'veterinarians,' 'veterinary paraprofessionals,' or aquatic animal health professionals are normally accredited or approved by the Veterinary Authority to deliver the delegated functions (OIE). The Veterinary Services protect and improve the health and welfare of animals, safe animal products, and veterinary biologics by preventing, controlling, and eliminating animal diseases, and monitoring and promoting animal health, animal welfare, and food safety. The OIE considers the Veterinary Services as a Global Public Good.

Introduction

The goal of Food Safety is that the consumers are able to trust that all food offered for sale is safe for its intended use. The last decades of the twentieth century have been the subject of increased concern in this area, related to numerous factors: changes in the production systems, much wider distances between the sites of breeding, production, and of consuming – particularly in industrialized countries – and occurrences of some new and emerging or reemerging diseases, such as the spongiform encephalopathies in ruminants. This period has stressed the critical importance of animal production and absolute necessity of a holistic approach to food safety and not only on the end products. This underpins the need for an integrated, multidisciplinary approach that covers the whole food chain and even beyond, such as feed for animal products, paradigm summarized with the famous 'from stable to table.'

OIE Involvement: The Animal Production Food Safety Working Group

Basic facts regarding Public Health show the following: 60% of human pathogens are zoonotic, 75% of emerging diseases are zoonotic, and 80% of agents having a potential bioterrorist use are zoonotic pathogens. Similarly, a great proportion of foodborne diseases is due to microbiologic pathogens of animal origin. It was hence recognized essential that the World Organisation for Animal Health (OIE) and the International InterGovernmental Organization (IGO) reference for animal

health and zoonoses gets involved in this area in close cooperation with other IGOs also working on Food Safety, such as the Codex Alimentarius, but from a different angle linked with its global mandate: "The improvement of animal health and welfare all around the world."

The Office International des Epizooties was created through the international Agreement signed on 25 January 1924 following outbreaks of devastating contagious animal diseases and in particular Rinderpest in Europe (nowadays totally eradicated worldwide – official recognition of the eradication in May and June 2011). In 1994, following the Marrakech agreement with the setting of the World Trade Organization (WTO) Agreement on the application of sanitary and phytosanitary measures (SPS), OIE was formally recognized as one reference organization by the WTO–SPS mandate to safeguard world trade by protecting human, animal, and plant health in conjunction with its two 'sister' organizations (Codex Alimentarius Commission (CAC) and International Plant Protection Convention). In 2011, OIE has a total of 178 Member Countries.

The third OIE Strategic Plan (2001–05) identified Food Safety as the first priority and at the 70th General Session in May 2002, the World Assembly of OIE delegates adopted resolutions defining the role of the OIE in this area aiming at strengthening its standard-setting activities in food safety through a new Animal Production Food Safety Working Group (APFSWG). The fourth OIE Strategic Plan (2006–10) supported the continuation of this mandate, recommending that the APFSWG "continue to work with other relevant organizations, especially the Codex Alimentarius Commission, in reducing foodborne risks to human health due to hazards arising from animals."

Hence, the OIE's goal for animal production food safety is to reduce foodborne risks to human health due to hazards arising from animals and hence provide better guarantee of safety of food of animal origin. It should be noted that these hazards include pathogens, which may not cause clinical signs in animals.

After adoption of the 2002 resolution, an ad hoc group of Experts chaired by the President of the CAC, was convened by the Director General in April 2002, and it pursued as a permanent working group of Animal Production Food Safety (APFSWG) in its series of meetings since then.

The terms of reference of this Working Group include among other items, the following:

1. Consideration of all foodborne hazards arising from animals before slaughter;
2. A primary focus on food safety measures applicable at the farm level;
3. Consideration of food safety measures applicable elsewhere, for example, during animal transport and harvesting of wild animals for food; and
4. Work criteria and priorities that take into account global food safety priorities and current work programs of relevant international organizations, especially the CAC.

Within these terms of reference, the role of this working group is to:

1. Provide advice to the OIE Director General on policy and strategic issues relating to the OIE's work on animal production food safety, which has the goal of reducing foodborne risks to human health by preventing, eliminating, or controlling hazards arising from animals before primary processing of animals and animal products and
2. Act in a steering group capacity, as required by the OIE Director General, regarding the work of OIE expert groups:
   a. Giving advice to the Director General on membership, scope, and terms of reference for expert groups and
   b. Reviewing texts arising from relevant expert groups for consideration by the relevant Specialist Commissions.

At its first meeting in November 2002, again chaired by the President of the CAC, the Working Group drew up a detailed work program for the OIE on the development of recommendations on animal production food safety covering pre-slaughter issues and those before the first transformation of the animal products, with the primary focus being on food safety measures applicable at the farm level. The Working Group also reviewed existing OIE Terrestrial Animal Health Code chapters dealing with food safety and zoonoses (brucellosis, tuberculosis, etc.), and recommended necessary changes in standards and additional work in accordance with the overall work program proposed by the Working Group.

A report of their work is delivered each year at the OIE General Session followed by resolutions giving the APFSWG its road book for the year ahead.

Priorities were given along this last decade and include the following:

1. Horizontal issues such as animal identification and traceability, good farming practices, guidelines for animal feeding, ante- and postmortem meat inspection standards, role of Veterinary Services in the reduction of public hazards;
2. Disease-specific OIE texts: Terrestrial Animal Health Code (Terrestrial Code) chapters on brucellosis, salmonellosis in eggs, etc.; and
3. Strengthening relationship between the OIE and the CAC.

Relevant documents were then drafted and later approved by the World Assembly of OIE delegates during various General Sessions this last decade, such as

1. The Guide on Good Farming Practices;
2. Guidelines for the control of hazards of animal health and public health importance through ante- and postmortem meat inspection;
3. Animal identification and traceability later followed by General Principles for identification and traceability of live animals incorporated in the Terrestrial Code (chapter 4.2);
4. Guidelines on the Detection, Control and Prevention of *Salmonella* Enteritidis and *S.* Typhimurium in Poultry Producing Eggs For Human Consumption;
5. Guidelines for the control of Hazards of Animal Health and Public Health importance in animal feed (chapter 6.3. of the Terrestrial Code);
6. Antimicrobial resistance (surveillance programs, chapter 6.7–6.11 of the Terrestrial Code) in coordination with the Codex Task Force;
7. Role and functionality of Veterinary Services throughout the food chain;
8. Review of a paper published on: Priority pathogens for standard setting by OIE.

In addition, the World Assembly of OIE Delegates, during the General Session of 2009 approved in its resolution XXIV, the expansion of the mandate of the Aquatic Animal Health Standards Commission to address Food Safety of products derived from aquatic animals. A first meeting of a working group focused on this issue had met in 2008. At its 2011 meeting, the group finalized the chapter 5.3 of the Aquatic Animal Health Code (Aquatic Code) dedicated to the "criteria to assess the safety of aquatic animal commodities."

Several ad hoc groups also tackle food safety issues in their meetings such as the OIE *ad hoc* groups on identification and traceability of live animal, on animal feeding, on pet food, on trade in animal products, on assessment of food safety related to the use of recombinant vaccines in food-producing animals.

Many seminars under the auspice of OIE and OIE publications, in particular the Scientific and Technical Review, were focused on the benefits for food safety issues to get the OIE and the Veterinary Services widely involved in prevention and control of foodborne diseases.

Among the key documents published by the OIE on food safety those last years, the following can be mentioned:

1. The Guide to good farming practices for animal production. This guide aims at describing a set of generic good farming practices intended to minimize hazards and to recommend good practices to address the listed hazards under six headings: general management, animal health management, etc. with a particular and original focus on animal feeding and watering. Its Appendix 1 is also most valuable as it draws a multientry table of "Hazards and their corresponding control points."
2. Priority pathogens for standard setting by the OIE related to animal production food safety. The authors used expert opinion and a literature review to identify the pathogens that were to be prioritized by the OIE for the development of future standards for animal production food safety. Interestingly, their conclusions were that *Salmonella* (from species other than poultry) and pathogenic *Escherichia coli* were considered as top priorities. *Brucella* spp., *Echinococcus granulosus*, and *Staphylococcus aureus* were also mentioned. The same article also lists the current coverage of farm level control of foodborne disease agents in the OIE Terrestrial Code or OIE guidelines.

OIE Involvement in Food Safety with the Veterinary Services

In addition to the extensive work of APFSWG, the OIE supports the improvement of food safety in the field by, the implementation of the rules to apply for Food Safety via the expertise of the national Veterinary Services. The latter are most often the national key focal points for all food safety issues as a great proportion of reported outbreaks of foodborne diseases is due to contaminations of foods with zoonotic agents, often during primary production. They act in their capacity to prevent and control foodborne zoonosis at the farm level or of other foodborne disease and chemical contamination of foods. They indeed exert their surveillance at all stages of animal production, on farm controls (animal health, feed, use of antimicrobial, identification, and traceability as well as animal welfare) and at the meat inspection level (ante- and postmortem inspections at slaughterhouses). They also provide certification of animal products for international trade.

In this context, the Director General of the OIE asked the OIE Delegates to nominate a national focal point for animal production food safety according to established terms of reference. The OIE also regularly organizes seminars for national focal points to provide information and contribute to capacity building of Veterinary Services.

Further to the implementation of the role of the Veterinary Services in the food chain from stable to table recommended by OIE, the OIE has put some emphasis both on capacity building and veterinary education. Wall stressed the big challenge for Veterinary educators to stimulate interest in public health medicine and make the curriculum relevant to those issues. The OIE in conjunction with the World Veterinary Year 2011 got also involved in trying to standardize the curriculum of veterinary education.

Close Cooperation with the CAC

Since its first involvement in this area, the OIE recognized that the goal to reduce foodborne disease due to hazards arising from animals can only be achieved in collaboration with the World Health Organization (WHO), the Food and Agriculture Organization (FAO), and their subsidiary body, the CAC. This is totally in line with the recent agreements signed between the Directors General of OIE, WHO, and FAO. The FAO–OIE–WHO tripartite strategic alignment recognize that addressing health risks at the human–animal–ecosystems interfaces require strong partnerships among players who may have different perspectives on some issues and different levels of resources.

The OIE has an SPS responsibility for elaborating international standards and related texts for the prevention, control, and eradication of animal diseases and zoonoses, whereas the CAC elaborates standards and related texts for both safety and suitability aspects of food control. CAC and the OIE have strategies and mechanisms in place to coordinate and integrate food safety activities across the production to consumption continuum and so enhance the safety of foods of animal origin on a worldwide basis. In terms of identification and traceability, for example, there is a clear need to strengthen bridges between animal and product traceability.

The terms of reference of the APFSWG include a link at the working level with the CAC (CAC, FAO, and WHO) and the working group has produced a guidance paper on the cooperation between the CAC and the OIE in food safety throughout the food chain. It identified as priorities an examination of the scope to develop joint OIE and Codex standards, address gaps and duplication in standards, and develop procedures for mutual recognition of standards where appropriate.

The cooperation between the CAC and the OIE currently include

1. Cooperation through mutual exchange of information and participation in meetings;
2. The use of a common text in the elaboration of a standard and harmonization of definition;
3. Cross-referencing to the other organization's standards; and
4. The construction of complementary texts taking into account the existing standards.

The next challenge in this cooperation approach is to set common working groups on specific topics, which would set the standards before following the respective procedures of these two organizations for respective official approval.

Conclusion

OIE plays a key role worldwide in Food Safety issues both at the starting points in elaborating and editing Codes of Practices or Standards for specified hazards of biologic origin and on the ground via its guidelines and capacity building to the national Veterinary Services. Through its specific working group APFSWG, the OIE has been an active partner of international organizations, and has been working in close cooperation with CAC, all having complementary functions and sharing the common approach of 'production to consumption' to food control.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Consumer Organizations

E Groth, Groth Consulting Services, Pelham, NY, USA

Consumer Organizations Involved in Food Safety and Food-Related Issues

Consumer organizations are a prominent sector of civil society; they speak for and represent consumers on a wide range of economic, safety, civil rights, and political issues. Consumer organizations have long been actively concerned with food safety, on scales ranging from local to global. Because they represent consumers and are independent from commercial interests, consumer organizations bring important and generally credible perspectives to food safety policy making.

What is a consumer organization? Consumers International uses this definition to determine eligibility for membership:

- The organization must have members drawn from the general public.
- It must be independent – that is, it should receive neither funding nor tangible support from any commercial entity with an interest in any issue the group addresses.
- It must be transparent – that is, the identities of those who direct and control the organization must be public.
- It must be democratically governed – by a board, a committee, or leaders chosen by its members – and should pursue issues and take positions supported by the members.

Consumer Organizations in a National Food Safety Context

Consumer organizations exist, to varying degrees, in virtually every country of the world. There are hundreds of consumer organizations in the world's 200 or so countries and their food safety interests span a wide spectrum of issues. On the one hand, consumer groups in Mali, Tanzania, and several other African nations have pressed local health authorities in recent years to oversee the safety of street-vended foods. On the other hand, consumer organizations in Europe and North America have lobbied their governments to regulate and label genetically modified foods.

Many consumer organizations, especially in developing countries, are essentially grass-roots community activists with very limited resources. Others, in both developed and developing parts of the world, have scientists and food-safety policy specialists in their staff, and bring professional expertise as well as a strong proconsumer perspective to bear on food safety issues. Some larger consumer organizations operate independent laboratories that test products for quality and safety, and publish magazines to inform consumers of their findings. Such organizations combine a scientific approach to testing, an educational outlook, and a commitment to improve the lot of consumers. This three-part mission is characteristic of consumer nongovernmental organizations (NGOs), both in countries where advanced consumer protection legislation and institutions exist and in nations where that protective framework, largely, still needs to be built.

For more than 50 years, consumer organizations have joined in international alliances, forging broad commonalities of outlook among consumer NGOs worldwide. At the same time, the consumer movement remains quite varied in its political outlook, its choice of issues, and the tactics it uses when pursuing its goals.

Most consumer organizations are concerned with food issues, given the fundamental importance of foods to all consumers. Consumer NGOs may address food sufficiency, nutrition and food quality, trade in foods and food safety; many work on all four. The full scope and diversity of consumer organizations' work on food safety issues cannot be covered in a brief article, but examples from two rather different countries may suggest both the variety of these efforts and some of their common themes.

In the USA, consumer organizations were instrumental in the campaign to pass the first national food safety law, in 1906, and were just as actively involved in the 2010 campaign that led to the passage of major new food safety legislation. One major US consumer NGO, Consumers Union, has worked for stronger food safety standards since 1936. Its recent priorities include regulation and labeling of genetically modified foods, safeguards to keep bovine spongiform encephalopathy out of US cattle herds, and better consumer information about methylmercury in fish. Another US consumer group, the Center for Science in the Public Interest, has created a database of outbreaks of foodborne pathogens for public use, filed numerous petitions with federal regulators to restrict potentially harmful food additives, and taken grocery chains to court for their failure to remove recalled foods from their shelves. Both organizations publish consumer magazines, each is engaged on a much wider range of food safety issues, and of course, these are but two of the many US consumer organizations that address some aspects of food safety.

In India, numerous consumer organizations work on food safety issues. The Voluntary Organization in Interest of Consumer Education (VOICE) has published a guide to food safety for consumers and advocates, tested soft drinks for pesticide residues, lobbied the Indian government for

restrictions on the use of genetically modified crops, and participated in the worldwide campaign for the safety of infant formulas. The Centre for Science and the Environment tested honey and found multiple illegal antibiotic residues. The Association for Consumer Action on Safety and Health (ACASH) promotes breastfeeding and lobbies to strengthen food safety regulations. The Consumer Education and Research Centre (CERC), which operates an independent product-testing laboratory, has found unacceptable levels of arsenic and fluoride in bottled water and widespread microbial contamination of processed foods, such as *Escherichia coli* and *Staphylococcus aureus* in milk and ice cream. These are just a few CERC food test reports available on its website, and these four organizations are but a small sample of the many Indian consumer NGOs working on various aspects of food safety.

Consumer Organizations in an International Food Safety Context

Just as foods and their associated safety issues cross national boundaries, many national consumer NGOs have joined with their sister organizations in other countries to work on food safety at the regional and global levels.

Very similar definitions of consumer organizations (comprised of ordinary citizens, independent, transparent, democratic, and international) are used by the World Health Organization (WHO), the Food and Agriculture Organization (FAO), and the Joint WHO/FAO Codex Alimentarius Commission to determine eligibility for observer status as a consumer international non-governmental organization (INGO). A relatively small number of organizations meet these criteria. Nevertheless, consumer INGOs have participated actively in international food safety deliberations for several decades. Codex has been the primary medium for this consumer involvement, but consumer INGOs have also engaged with WHO, FAO, and the World Trade Organization on food safety issues at the Global Forums on Food Safety, and in other contexts. For brevity's sake, the focus here is on consumer participation in Codex, but the consumer role at other food safety-related intergovernmental bodies has been similar to that in Codex.

In early 2011, there were 199 registered Codex observer organizations. Of those, eight were international consumer-oriented public-interest organizations. Each organization, and the role it has played at international food safety bodies, is described briefly below. The eight organizations are:

- 49th Parallel (49P)
- Bureau Européen des Unions de Consommateurs (BEUC)
- Consumers International (CI)
- Greenpeace International (Greenpeace)
- International Association of Consumer Food Organizations (IACFO)
- International Baby Food Action Network (IBFAN)
- National Health Federation (NHF)
- Pesticide Action Network (PAN)

Several of these consumer observers are essentially single-issue organizations; for example, 49P is concerned almost exclusively with genetically modified foods, and IBFAN works only on infant feeding issues. But at least two consumer observers, CI and IACFO, have broad food safety portfolios and have participated over the years at multiple Codex committees and at other food safety meetings. The breadth and depth of their interests and their highly professional interventions have enabled consumer INGOs to play a more significant role in international food safety deliberations than their small numbers might suggest.

Profiles of Individual Consumer Observer Organizations

Consumer-based Codex observer organizations represent a variety of perspectives, geographical regions, and issue interests. They are listed here in alphabetical order. Further details on each, including their national members where applicable, can be found on the websites listed at the end of this article.

49th Parallel (49P)

49th Parallel is a small organization with membership in the northwestern USA and southwestern Canada (where the 49P the parllel forms the international boundary). 49P's main interest is foods and food ingredients derived from genetically modified organisms. It has attended the Codex *Ad Hoc* Task Force on Foods Derived from Biotechnology, several meetings of the Codex Committee on Food Labeling where international standards for labeling genetically modified foods were being deliberated, and meetings of the Committee on General Principles and the Codex Commission when issues of interest to 49P were on the agenda.

Bureau Européen des Unions de Consommateurs (BEUC)

BEUC, known in English as The European Consumers' Organization, is an alliance of 44 consumer organizations from 31 European countries. BEUC is the European branch of CI. It participates at the Codex Regional Coordinating Committee for Europe, representing CI's European members. At all other Codex bodies and in other international food safety forums, BEUC and its members are usually represented by CI.

Consumers International (CI)

CI is the oldest and largest international association of consumer organizations, with some 220 member organizations in 115 countries in all regions of the world. CI first began participating at the Codex Commission in the 1970s, and has done so more or less continuously since then.

In the 1990s, CI expanded its international food safety work in response to growing member interest in the topic. CI members in the USA, the UK, and several European countries led the effort, assigning their own food safety experts to take part (as CI) at many Codex committees and other international food safety gatherings. At the peak of its activity, CI was engaged in the work of at least 17 different Codex bodies, including the Commission; all six regional Codex coordinating committees; subject committees on Food Labeling, General Principles, Food Hygiene, Food Additives and Contaminants, Pesticide Residues, Residues of Veterinary Drugs in

Foods, Nutrition and Foods for Special Dietary Uses, and Import/Export Certification Systems; and *Ad Hoc* Task Forces on Foods Derived from Biotechnology, and on Management of Antimicrobial Resistance. CI sent experienced delegates to meetings, often submitted detailed written comments on draft documents, and participated in voluntary working groups that met between meetings to draft and revise those documents.

CI also sent delegations to the WHO/FAO Global Forums on Food Safety in 2002 and 2004. Several individuals from CI member organizations have participated as invited experts in joint WHO/FAO expert consultations and similar scientific meetings.

Because of the breadth of its interests, and because its delegates brought expertise on issues, experience in international meetings, and a diplomatic attitude to the table, CI has the played a robust and effective role in international food safety forums for many years.

During the late 1990s, with grant support, CI expanded its presence to include delegates from its members in developing countries. These diversified delegations broadened CI's interactions with national delegations and gave many CI member organizations, new to the process, an opportunity to learn how to participate effectively in global food safety policy making. By building the capacity of its own members, CI also increased its presence at the regional codex coordinating committee meetings, especially those in Africa, Asia, and Latin America.

In recent years, CI's international food safety work has significantly diminished. Key experienced delegates left CI member organizations; grants ran out; and most CI members faced competing needs. As the food-related policy priorities of CI as a whole diversified, an intensive emphasis on Codex-work no longer seemed appropriate, and resources were redirected elsewhere.

Today, CI's involvement in Codex and similar international food safety activities, although still substantial, is a slim shadow of what it once was. CI tracks food safety issues that most concern its members (such as genetically modified foods, safety of infant formulas, and antimicrobial resistance) and attends meetings where those issues are addressed. In recent years, CI's strongest presence has been at the Committee on Food Labeling and the *Ad Hoc* Task Force on Antimicrobial Resistance. CI still attends Codex Commission and General Principles meetings, and keeps its members informed on the status of issues that interest them. CI nowadays is as likely to be represented by someone from Uganda as by someone from the UK, and rarely sends multinational delegations to meetings.

Greenpeace International

Greenpeace International has not often participated at Codex or in other global food safety forums. Greenpeace did join other consumer INGOs attending the 2009 Codex Committee on Food Labeling to lobby in favor of labeling of genetically modified foods.

International Association of Consumer Food Organizations (IACFO)

IACFO was established in 1997; in 2011, it had 12 member organizations in North America, Europe, Asia, and Africa. IACFO is interested in all aspects of international trade in foods, including food safety. IACFO has attended meetings of the Codex Commission and the Committees on General Principles, Food Labeling, Food Hygiene, Residues of Veterinary Drugs in Foods, International Import and Export Certification Systems, and Nutrition and Foods for Special Dietary Uses. IACFO also has participated in deliberations of WHO, FAO, the World Trade Organization, and the Organization for Economic Cooperation and Development (OECD).

In 2004, IACFO created a second global consumer food safety entity called Safe Food International (SFI), described as a project to empower consumer organizations to improve food safety on a global level. SFI developed a set of guidelines for consumer organizations wishing to pursue that goal, and in 2005, organized an international conference at which consumer organizations met with national food safety officials and experts from FAO, WHO, and other intergovernmental bodies.

IACFO's participation in international food safety activities has been led by experts at its US member, the Center for Science in the Public Interest. IACFO has been able to maintain a consumer presence at several critical Codex committees, including Food Hygiene and Veterinary Drugs, after CI could no longer do so, and is probably the most broadly involved consumer organization now working on global food safety issues.

International Baby Food Action Network (IBFAN)

IBFAN is, as its name indicates, concerned with infant feeding issues. Formed in 1979, IBFAN is an alliance of public-interest groups from Africa, Latin America, Asia, Europe, and other regions. As a single-issue organization, IBFAN has interacted with global and regional intergovernmental agencies (such as WHO, United Nations International Children s Fund (UNICEF), and the Pan-American Health Organization (PAHO)) that address infant nutrition policies. At Codex, IBFAN has been involved at the committees on Nutrition and Foods for Special Dietary Uses and on Food Labeling, and participated in the Food Hygiene committee's effort to set microbial safety standards for infant formulas. IBFAN has also attended meetings of the Codex Commission, the Codex Committee on General Principles, and on occasion, some Regional Codex Coordinating Committees.

IBFAN was instrumental in lobbying for the International Code on Marketing of Breastmilk Substitutes, adopted by the World Health Assembly in 1981, helped organize a boycott of Nestle over its infant-formula marketing practices in developing countries, and is currently active in Codex efforts to set standards for the nutrient composition and nutritional labeling of infant formula. Several of IBFAN's member organizations have formed a Codex Working Group to coordinate inputs by the global IBFAN network into the Codex process. The working group has submitted detailed technical comments on some of the Codex drafts, and sent delegates to make expert interventions at Codex meetings.

Because of its single-issue focus, its representation of lower-income consumers from all corners of the earth, the ethical leverage associated with representing babies, and the quality of its experienced, knowledgeable delegates, IBFAN has been one of the most effective consumer INGOs working on global food safety.

National Health Federation (NHF)

NHF is a global association of consumer health advocacy organizations with members in at least 20 countries. First established in 1955 as a national organization in the USA, NHF describes itself as a defender of health freedom. It has participated at the Codex Committee on Nutrition and Foods for Special Dietary Uses, chiefly to oppose standards that it perceives might restrict consumers' rights to buy nutritional supplements. NHF has also joined other consumer observers to support a Codex standard for labeling of genetically modified foods.

Pesticide Action Network (PAN)

PAN is an international alliance of environmental, farm-worker, and consumer advocacy organizations that promotes pesticide safety in a variety of contexts. PAN has been actively involved with the FAO's Agriculture Committee and with the United Nations Environment Program. Pesticide residues in foods are one of PAN's many concerns, and PAN has attended occasional past sessions of the Codex Committee on Pesticide Residues.

Conclusions

The consumer movement is actively engaged in the food safety policy process at all levels, from strictly local to national and global scales. This participation has benefitted consumers and enriched the process. The consumer perspective is independent and often valuable, and sometimes brings substantial insights and expertise to bear on issues that might not have been presented by other stakeholders. Although the intensity of their participation has ebbed and flowed over the years as resources wax and wane, consumer INGOs are a fixture in the world food safety system and are likely to play a significant role in the future.

INSTITUTIONS INVOLVED IN FOOD SAFETY

National Industry Organizations – Case of UK Food and Drink Federation

K Chinyama, Food and Drink Federation, London, UK

Glossary

Codex Alimentarius The Codex Alimentarius is a body of standards decided by the Codex Alimentarius Commission to protect the health of consumers and to ensure fair practices in international food trade. The Codex Alimentarius Commission is a joint FAO/WHO organization.

Contaminant Any substance not intentionally added to food, which is present in such food as a result of the production (including operations carried out in crop husbandry, animal husbandry, and veterinary medicine), manufacture, processing, preparation, treatment, packing, packaging, transport or holding of such food, or as a result of environmental contamination. The term does not include insect fragments, rodent hair, and other extraneous matter (definition adopted by Codex Alimentarius Commission).

Genetic modification (GM) A process of altering the genetic makeup of an organism by techniques of modern biotechnology.

Hazard analysis critical control points (HACCP) A system that identifies, evaluates, and controls hazards that are significant for food safety.

Incident Any event which, based on the information available, causes concern about actual or suspected threats to the safety or quality of food that could require intervention to protect consumers.

Rapid Alert System for Food and Feed (RASFF) A notification system for incidents in the EU, which is coordinated by the European Commission.

Overview of the Food Industry Organizations

The Food and Drink Federation (FDF) is the UK representative of FoodDrinkEurope, the confederation of the European food industries (the umbrella trade association for the European food and drink industry). As of January 2010, membership of FoodDrinkEurope was made up of: 26 national federations, including 3 observers, 26 EU sector associations, and 20 major food and drink companies. FoodDrinkEurope aims to promote and represent the interests of the food and drink industry in the EU and beyond. It covers issues such as food quality and safety, nutrition and health, novel foods, labeling, agricultural policy, international trade matters, sustainable development, respect for the environment, and enlargement of the EU. The food and drink industry is one of the Europe's most important and dynamic industrial sectors.

More information on the European food associations and federations that are part of FoodDrinkEurope can be found on the FoodDrinkEurope website. A list of the major associations can also be found on the European Commission, Enterprise, and Industry website.

Below are a few examples of some of the sectoral associations:

- Association of the Chocolate, Biscuit and Confectionery Industries (CAOBISCO) – represents approximately 2000 companies of the chocolate, biscuits, and confectionery sectors of the EU.
- European Sugar Manufacturers Committee (CEFS) – represents all European sugar manufacturers and refiners.
- European Dairy Association (EDA) – represents the European dairy industry.
- European Snacks Association (ESA) – is Europe's trade organization dedicated to advancing the savory snacks industry on behalf of member snack manufacturers and suppliers.
- The Federation of European Union Manufacturers and Suppliers of Ingredients to the Bakery, Confectionery, and Patisserie Industries (FEDIMA) – represents the intermediate products industries for the bakery and confectionery trades.
- Union of European Beverages Associations (UNESDA) – represents the nonalcoholic beverages manufacturers in the EU.

The food industry organizations are structured in a similar way. The common feature of these trade associations is that they have a policymaking body in their structure as well as committees or working groups that discuss specific issues and oversee the day-to-day management of issues. *Ad hoc* groups or task forces can also be set up within a working group or committee to address specific issues. All the businesses are governed by EU legislation. The sectors/associations influence the environment in which their members operate. There are horizontal legislations formed in Brussels and vertical legislations covering products in different sectors. In addition to

legislation, below are some of the aspects addressed by sectors or associations:

- Representing, promoting, and protecting members' interests.
- Policy developments on food safety and quality, nutritional health, sustainability and market management as part of the EU Common Agricultural Policy (CAP), as well as guaranteeing the right to be competitive and innovative.
- Promoting dialogue and exchange of information at technical and legislative levels, for example, on additives, labeling, food quality, environment, nutrition and diet, with the European Commission, European Food Safety Authority (EFSA), national regulators, and other international bodies like Codex.
- Keeping members informed of EU developments.
- Working with legislators and regulators with the aim of improving the workability, proportionality, or enforceability of legislation by consulting and contributing on behalf of members to the setting up or review of European legislation directly affecting members.

An overview of how the national federations within the EU food industry work is reflected in the structure and function of the description given for FDF and its sector associations. The details and exact structures or membership may differ with each national federation, association, or sector within the EU Member States. However, the overall objective is to represent, promote, and protect the particular interests of the members of the concerned sector, association, or federation.

Food and Drink Federation

FDF is the voice of the UK food and drink industry. FDF is a trade organization representing, promoting, and safeguarding the interests of the UK food and drink manufacturing industry in relation to scientific issues and regulatory systems and associated developments which impact on the production and sale of food and drink products.

FDF represents the interests of the UK's food and non-alcoholic drinks manufacturing industry, the largest manufacturing sector in the UK, employing more than 400 000 people. The industry has an annual turnover of £72.8 bn accounting for 15% of the total manufacturing sector. Exports amount to almost £10 bn of which 79.2% goes to EU members. The industry buys two-thirds of all UK's agricultural produce. FDF membership comprises manufacturers of all sizes as well as trade associations dealing with specific sectors of the industry.

Member Services and Sector Groups

FDF is a membership-based organization. Its policies are developed through industry-wide consultation channeled through its governing Council, advised by specialist committees/panels, and informed by sector networking groups. Current FDF membership comprises of 13 associations, 7 sector groups, and other membership organizations (See annex) (Figure 1).

In Scotland, Wales, and Northern Ireland, some government policies and public services are different from those in

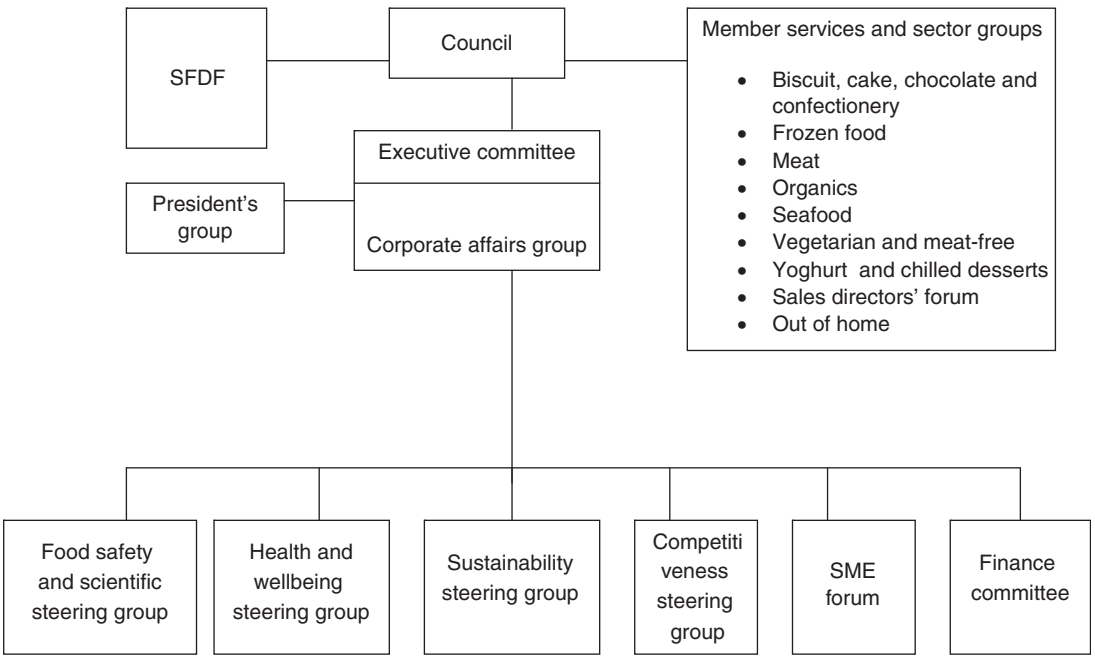

Figure 1 FDF organizational structure. SFDF, Scottish Food and Drink Federation; SME, small- and medium-sized enterprises.

England. Since 1999, the UK central government has given certain powers to devolved governments, so that they can make decisions for their own areas.

Scottish FDF (SFDF) is a devolved division of FDF and is 'the voice' of food and drink manufacturers in Scotland, ensuring the Scottish food industry is heard where it matters in the Scottish, UK, and EU contexts.

Each sectoral organization represents the specific interests of its group. For example the Biscuit, Cake, Chocolate, and Confectionery (BCCC) Group represents the specific interests of UK biscuit, cake, chocolate, and confectionery manufacturing/supplying/marketing companies. The Group is the representative and influential voice of the sector, promoting the industry and representing its viewpoint to the government, to all relevant regulatory, scientific, and enforcement authorities, and other public bodies.

In addition, the Group is the UK representative body on the EU organization representing the product sector, i.e., CAOBISCO, so as to play a full part in influencing EU policy matters which impact on the sector.

Food and Drink Federation Vision and How We Work

The core areas of FDF's work are:

- Food safety
- Promoting the competitiveness of the food and drink industry
- Health and well-being
- Sustainability
- Communications

Food Safety

The overall FDF vision enshrined in its core areas of work is that stakeholders, including government and consumers, trust the UK food and drink industry and have confidence both in the safety of FDF members' products, and from a health and well-being perspective, to see the industry as socially responsible and to know that all products can fit into a balanced lifestyle. The vision from a competitiveness point of view is for stakeholders to understand and value the economic contribution of the UK food and drink sector and for this to be fully taken into account in government policy-making and to realize that the industry is working to improve its sustainability – economically, environmentally, and socially.

The Food Safety and Scientific Steering Group, supported by its committees, is at the core of FDF activities and seeks to ensure that all FDF policies are rigorously science-based, including the scientific underpinning of the work of other divisions in FDF and their activities such as the Health and Well-being, Competitiveness, and Sustainability Steering Groups. The Food Safety and Scientific Steering Group represents, promotes, and safeguards the interests of the UK food industry in relation to scientific issues and regulatory developments. Its role is central to supporting and communicating food safety and science as pillars of FDF's work.

Within the Food Safety and Scientific Steering Group, there are seven issue-led committees to facilitate more detailed discussion of specific issues; these are:

- Food Chain Issues, covering issues relating to the safety of the supply chain in respect of food raw materials and animal feedstuffs, and including the overarching issues of GM, novel foods, and nanotechnology;
- Food Contact Materials, dealing with the safety of packaging materials in immediate contact with food and food ingredients;
- Food Hygiene, including EU food hygiene legislation, hazard analysis critical control points (HACCP), and microbiological food safety;
- Food Ingredients, dealing with developments relating to the use of additives, flavorings, enzymes, and processing aids;
- Food Law and Labeling, covering general food law and food labeling;
- Nutrition, which includes developments in the science in relation to diet and health, obesity strategy, reformulation, portion sizes, nutrition and health claims, and nutrition profiling; and
- Residues and Contaminants, which deals with the safety of raw materials throughout the supply chain in terms of chemical and other contaminations. This includes process contaminants and plant protection products.

Each work area comprises a list of priority topics followed by issues to be monitored, with a view to action if appropriate. A continuing requirement for each committee will be to identify emerging issues and assess the need for action, which may necessitate a revision of established priorities. The work program for each committee is reviewed and updated annually.

All these committees assist FDF members in meeting the requirements of the legislation. In addition, FDF uses the science base to drive development, innovation, and reformulation of products. For example, under nutrition, the science of nutrition and our ability to apply it to drive health and well-being in consumers is seen as a key indicator of whether the food and drink industry is perceived as being one that is responsible and able to move with the times – be these developments in the realms of pure or applied (e.g., social) science.

The roles of the Competitiveness and Sustainability Steering Groups are to provide strategic and proactive leadership on competitiveness issues and lead on sustainability and environmental issues affecting the well-being of the food and drink manufacturing industry, respectively.

From time to time, FDF will also form *ad hoc* technical groups when input is required on particular issues.

FDF's communication programs aim to enhance the industry's reputation as a responsible provider of safe food products and reliable information.

Informing and Consulting Members

FDF ensures that members stay abreast of the advances in science that change our understanding of food safety issues and FDF promotes the need for appropriate risk assessment and reduction strategies by regulators.

FDF enhances the coordination of the industry's approach and response to scientific and regulatory issues, and food safety incidents, by provision of timely information and advice to members, and by undertaking consultation as appropriate.

FDF liaises and develops partnerships, including where appropriate joint positions, with supply chain organizations, including retail, food service, farming, scientific, academic, and other organizations that are part of the food chain including consumer organizations.

Food Safety and Science is Key to Our Work

The safety of food products is the top priority for the food industry and this is reflected in FDF's positions on key issues. As part of their due diligence requirement, manufacturers need to have robust systems in place to ensure that from the time of harvest or slaughter to the time of consumption, product safety is monitored and maintained – whether the potential threat comes from chemical contamination, physical objects, or microbiological infection.

As such FDF ensures that members stay abreast of advances in science that may change FDF policy toward food safety or approach to appropriate risk assessment, risk management, and risk communication by national and European regulators.

It is important to remember that science also brings opportunities for product and process innovation and FDF works with members to develop policy positions to address emerging technologies which explain how these developments can provide real benefits for consumers. FDF's secretariat and committees also work to ensure that regulatory approaches to food information to consumers and nutrition are based on science.

Link with Food Research Organizations

To keep abreast of advances in science, FDF member companies are also members of independent membership-based organizations that carry out research and development for the food and drinks industry worldwide, such as Leatherhead Food Research and Campden BRI. These food research organizations are also affiliate members of FDF.

These food research organizations help the food industry meet their daily and long-term technical, scientific, information, and training needs. They help the industry to innovate and evolve by offering services including market intelligence, food research and analysis, food legislation, business and technical information, and training.

Compliance with Food Legislation

The safety of food and drink products, and their delivery in prime condition along the food chain to consumers, is the key priority of the food and drink manufacturing industry. In this respect, the food and drink industry is highly regulated and carefully monitored to ensure the safety and integrity of the food supply chain.

The Food Safety Act 1990 (as amended) provides the framework for all food legislation in Great Britain – similar legislation applies in Northern Ireland. This is an important act in Great Britain, which updated previous law on food safety and consumer protection. This has been in existence since before the 'General Food Law' Regulation (EC) No 178/2002, which covers EC legislation on general food safety.

According to the General Food Law, in the market, it is prohibited to put food which is unsafe (article 14). The legislation covers hygiene, microbiological contamination, residues, and contaminants. There are also more specific regulations, for example: on food additives, Regulation (EC) No 1333/2008; Enzymes Regulation (EC) No 1332/2008; Flavourings Regulation (EC) No 1334/2008, and Regulation (EC) No 258/97 on novel foods, which is currently under review. These regulations are applicable to the risk assessments of specific ingredients and how they are processed, as appropriate.

Framework Regulation (EC) No 1935/2004 on materials and articles intended to come into contact with food as well as legislation on active and intelligent materials, and articles in contact with food are applicable to packaging material. Compliance with this legislation is necessary to ensure compliance with general food law. There are also commodity specific 'directives' or regulations, for example, on chocolate, jam, etc.

As the body of legislation bearing down on the food industry continues to grow, FDF works closely with its European counterpart, FoodDrinkEurope, and European sector associations, to ensure that the industry's voice is heard in the right places and at the right time within the EU. The industry's input ensures that harmonized legislation is in place in order to ensure the free movement of food and feed in the EU and to comply with international standards where necessary.

The Food Chain

The inherent perishability of food from the time of harvest or slaughter requires food manufacturers to be continually vigilant in maintaining product safety – whether from the threat of chemical, physical contamination, or microbiological infection. FDF's work covers developments and issues that impact on the production and sale of food and drink products, specifically:

- food safety, processing, and composition;
- the labeling and presentation of the final product; and
- nutrition, diet, and health.

This involves a whole food chain approach, constructively influencing the regulatory environment in which the industry operates, working with Government and others to improve confidence in the safety of the food supply, and addressing sustainability and competitive issues in the related regulatory systems.

The food chain encompasses a number of players from primary producers through to consumers. This chain is wide, complex, and global (Figure 2). As such, transparency and compliance with legislation is needed throughout the chain to ensure that food safety is achieved. Hence, responsibility for

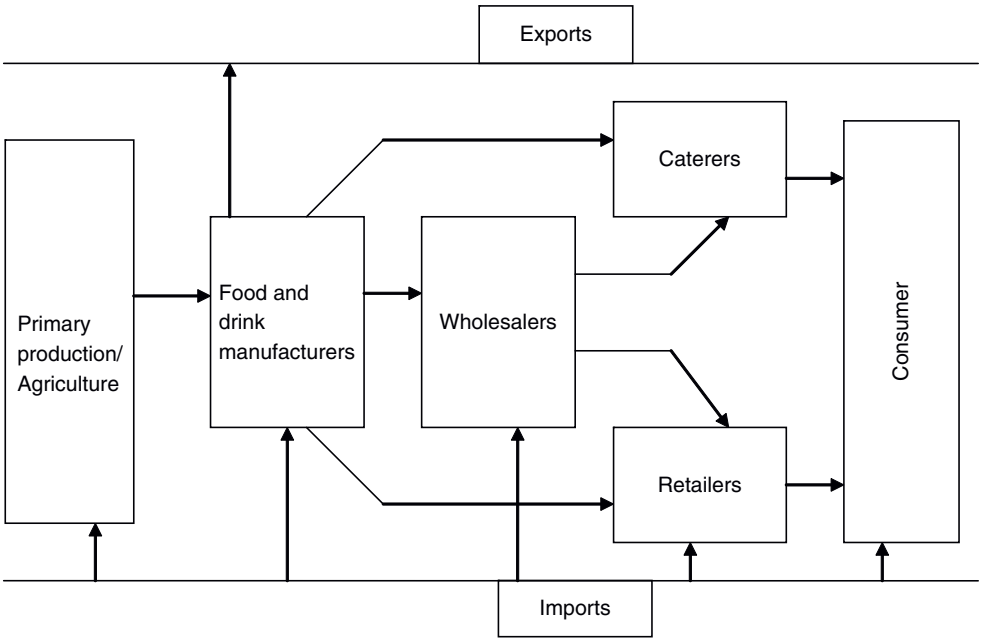

Figure 2 Interaction of the food chain stakeholders. *Source*: Institute of Manufacturing, University of Cambridge, Report to FDF, Value of Food and Drink Manufacturing to the UK, July 2010.

food safety is shared by everyone involved with food, from primary production to consumption, including growers, processors, regulators, distributors, retailers, and consumers.

Responding to Food Incidents

In addition to the objective to seek proportionate and evidence-based legislation that control food, FDF also assists members in the prevention of incidents through the work of the Incident Management Working Group, including identifying the root causes of incidents and horizon scanning for emerging issues. Although the food and drink industry strives to follow and maintain food standards, guides, and codes of practice and legislation along the food chain, incidents do happen now and again. Notable examples of incidents affecting the food industry in recent years are melamine contamination of milk in China, Sudan I contamination of spices originating from India, and dioxins contamination of guar gum from India. With the increasing globalization and complexity of the food chain, trade of food, food ingredients, and agricultural products around the world are continuing to increase; this also increases chances of food incidents happening along the food supply chain. Some of the contaminations are deliberate, i.e., fraud, and some are accidental. As such, FDF promotes and fosters the proportionate handling of food safety incidents at national and EU level.

FDF's Incident Management System assists the food industry in taking prompt action in response to emerging or potential food safety incidents. At national level, the Food Standards Agency (FSA) leads on incidents in liaison with the EU Rapid Alert System for Food and Feed (RASFF), which is managed by the European Commission. FDF helps its members by ensuring that food safety incidents, when they happen, are handled in a proportionate way, at national and EU level, and FDF coordinates an effective industry response to any such incident. FDF assists by cascading information from FSA, FoodDrinkEurope, and the Commission. FDF also consults members for the necessary information that may be required from industry regarding a particular incident.

Partnership

FDF helps its members operate in an appropriately regulated marketplace to maximize their competitiveness. FDF communicates the industry's values and concerns to Government, regulators, consumers, and the media. FDF also works in partnership with key players in the food chain to ensure that our food is safe and that consumers can have trust in it. This involves working with various UK Government departments including FSA, Department for Environment Food and Rural Affairs (Defra), Department of Business, Innovation and Skills (BIS), Local Government Regulation (Enforcement Authority), and others including the European Commission, European Parliament and EFSA, Codex, and FoodDrinkEurope to improve confidence in the safety of the food supply by seeking proportionate and evidence-based legislation.

Annex

The following Associations are members of the FDF:
ABIM Association of Bakery Ingredient Manufacturers
ACFM Association of Cereal Food Manufacturers
BCA British Coffee Association
BOBMA British Oats and Barley Millers Association

INSTITUTIONS INVOLVED IN FOOD SAFETY

International Organization for Standardization (ISO)

M Petró-Turza, formerly Budapest Technical University, Budapest, Hungary

Glossary

Control measure Action or activity that can be used to prevent or eliminate a food safety hazard or reduce it to an acceptable level.

International standard Standard that is adopted by an international standardizing/standards organization and made available to the public.

International standardization Standardization in which involvement is open to relevant bodies from all countries.

Operational prerequisite program (oPRP) PRP identified by the hazard analysis as essential in order to control the likelihood of introducing food safety hazards and the contamination or proliferation of food safety hazards in the product(s) or in the processing environment.

Prerequisite program (PRP) Basic conditions and activities that are necessary to maintain a hygienic environment throughout the food chain suitable for the production, handling, and provision of safe end products and safe food for human consumption. Note: The PRPs needed depend on the segment of the food chain in which the organization operates and the type of organization. Examples of equivalent terms are: good agricultural practice (GAP), good veterinarian practice (GVP), good manufacturing practice (GMP), good hygienic practice (GHP), good production practice (GPP), good distribution practice (GDP), and good trading practice (GTP).

Process An activity using and managing resources in order to enable the transformation of inputs into outputs. Often the output from one process directly forms the input to the next.

Process approach Application of a system of processes within the organization, together with the identification of interactions and the management of these processes.

Standard Document, established by consensus and approved by a recognized body, that provides, for common and repeated use, rules, guidelines, or characteristics for activities or their results, aimed at the achievement of the optimum degree of order in a given context. Note: Standards should be based on the consolidated results of science, technology, and experience, and aimed at the promotion of optimum community benefits.

Standardization Activity of establishing, with regard to actual or potential problems, provisions for common and repeated use, aimed at the achievement of the optimum degree of order in a given context. Note: (1) In particular, the activity consists of the processes of formulating, issuing, and implementing standards; (2) important benefits of standardization are improvement of the suitability of products, processes, and services for their intended purposes, prevention of barriers to trade, and facilitation of technological cooperation.

Standardizing body Body that has recognized activities in standardization.

About International Organization for Standardization in General

The International Organization for Standardization (ISO in each language) is the world's largest developer and publisher of International Standards. ISO was the first established international standardizing organization. Officially, ISO began operating in 1947 with 25 national standards institutes as its members (one per country) and at present, the number of its member bodies is 162. The system of this global scale network of national standards institutes is coordinated by the ISO Central Secretariat, located in Geneva, Switzerland.

ISO has more than 3000 technical bodies, among them approximately 200 active technical committees for developing ISO standards; and more than 50 000 experts for participating in its activity. ISO has more than 17 500 International Standards and other types of normative documents in its current portfolio. The technical work of ISO is regulated by a stringent procedure which was developed and continuously improved since ISO's existence. The overall coordination of this technical work is made by the ISO Technical Management Board. The above mentioned data speak for themselves and show that in the past more than 60 years ISO has kept its leading role in international standardization.

ISO deals with the full spectrum of human activity with the exception of electrical and electronic engineering where International Standards are developed by the International Electrotechnical Commission (IEC) as well as the

telecommunication sector, which is the area of International Telecommunication Union (ITU). ISO work program ranges from standards for traditional activities, such as agriculture and construction, through mechanical engineering, manufacturing, and distribution, to transport, medical devices, information, and communication technologies, and to standards for good management practice and services.

Considering the fact that ISO members are not national governments, but the national bodies most representative of standardization in their respective countries, ISO is a non-governmental organization that forms a bridge between the public and private sectors. Many of its member institutes are part of the governmental structure of their countries, or are mandated by their government. Other ISO members have their roots uniquely in the private sector, having been set up by national partnerships of industry associations. Therefore, ISO enables to reach consensus that meet both the requirements of business and the broader needs of society.

ISO standards are voluntary and it does not enforce their implementation. A certain percentage of ISO standards – mainly those concerned with health, safety, and environment – has been adopted in some countries as part of their regulatory framework, or is referred to in legislation for which it serves as the technical basis. However, such adoptions are sovereign decisions by the regulatory authorities or governments of the countries concerned. ISO itself does not regulate or legislate.

Although ISO standards are voluntary, the fact that they are developed in response to market demand, and are based on consensus among the interested parties, ensures their widespread use.

Food Standardization in International Organization for Standardization

Since the beginning, ISO has dealt with food standardization. The majority (70%) of this type of ISO standards specifies analytical or test method. A part of them is suitable for the determination of physical or sensory properties of foods or for the determination of their chemical compound(s); others are used for the measure the extraneous and/or foreign matter content or microbiological contaminations; again others are suitable for the detection and/or determination of toxic materials or genetically modified organisms in food products; whereas other methods are developed for the detection of food adulteration. The suitability of most of the ISO methods is checked by international ring tests. Therefore, many ISO methods are recognized by the Codex Alimentarius Commission.

The second group of ISO food standards (12%) deals with product specifications, majority of them concerns spices and a few concern cereals. The relatively low proportion of this type of ISO standards can be explained by the fact that most of the product specifications are standardized by the Commodity Codex Committees.

There are ISO food standards dealing with storage conditions and transport (9%), whereas others specify sampling procedures (4%). Among the remainder (5%) the group containing vocabularies or nomenclatures is worth highlighting. These International Standards edited trilingually or bilingually are comprehensively used in the world trade and accepted by other international organizations as well.

Food Safety Standards of International Organization for Standardization

As the food safety is a typical area of the Codex Alimentarius Commission, ISO started to deal with this question rather late, in 2001, because of the huge demand of its member bodies. At that time the hazard analysis and critical control point (HACCP) system was already well known and used around the world. Therefore, it is a fair question why does the need for an ISO standard arise?

The main problem with the HACCP system is its general and brief text, which:

- allows various interpretations resulting in huge differences in the implementation and in the acceptance criteria;
- does not give enough help for the food producers in the practical application of the system; and
- does not contain auditable requirements as this Codex document is only a recommended guideline.

Following the success of the ISO 9000 standard series, certified management systems have increasingly become a general requirement for access to both national and international markets. Therefore, many retailer syndicates have prepared food safety auditing standards e.g., the British Retailer Consortium (BRC), the European Food Safety Inspection Service (EFSIS), or the International Food Standard (IFS) developed by German and French companies on the basis of BRC and EFSIS, and require their suppliers to develop food safety management systems and obtain certification to these standards. Although it is stated that these standards do not differ significantly from each other, certification according to one is accepted only in a few cases by another.

The reasons that led to the development of ISO 22000, the basic food safety standard of ISO, can be summarized as follows:

- increasing number and severity of regulations and controls relating to food safety;
- greater extent of customers' requirements (owing to their increased knowledge of the health effects of nutrition and the risks of food safety);
- HACCP systems in place but with differing requirements and implementation in different countries and for different foodstuffs;
- food producers have to comply with different requirements depending on the country and customer; and
- retailers are certifying and inspecting food producers and have set a variety of specific criteria.

The solution to the above mentioned problems was awaited from ISO, as it was the most recognized international standardization organization, which developed the well-known management system standards (ISO 9001, ISO 14001), new ones (e.g., for information security (ISO/IEC 27001), and for supply-chain security (ISO/PAS 28000)).

International Standard ISO 22000:2005, Food Safety Management Systems – Requirements for Any Organization in the Food Chain

In the development of this new ISO standard, experts from more than 40 countries took part and it was published in September 2005. ISO 22000 constitutes an internationally recognized food safety management system allowing an organization to implement and demonstrate compliance with the relevant documents of Codex, thus simplifying/clarifying the customer/supplier relationship. ISO 22000:

- although arranged differently, includes each principle and application step of the HACCP system, so standardizes its implementation and the basic criteria for its acceptance;
- completes HACCP with more detailed instructions regarding its application;
- contains auditable requirement; and
- Annex B contains cross references between HACCP and ISO 22000 to promote the combination of the two systems.

However, ISO 22000 is much more than the HACCP itself, as it combines the HACCP system with the prerequisite programmes (PRPs) and with the quality management system (QMS).

ISO 22000 categorizes the control measures into the following three groups:

- PRPs,
- operational prerequisite programmes (oPRPs), and
- HACCP plan and its critical control points.

PRPs ensure the basic conditions and activities which each member of the food chain should perform. These help in maintaining a hygienic production, processing, and handling environment. PRPs do not need validation but their effectiveness shall be verified periodically.

Both of the other types of control measures are managing control measures identified by the hazard analysis and both shall be validated and verified.

ISO 22000:2005 introduced the new term, oPRP, to handle those control measures that, for any reason, cannot be included or those that it is not necessary to include in the HACCP plan as critical control points. For example, the critical limit of the given hazard cannot be determined, or can be determined but cannot be validated, or the incidence rate of the given hazard is relatively low. This makes it possible to focus the HACCP plan at the most critical hazards, and keep all others under appropriate control.

Among the management system elements of ISO 22000:2005, the following should be highlighted:

- interactive communication (internal and external);
- structured processes/process approach (help to identify and manage numerous linked activities);
- commitment of top management (management responsibility); and
- keeping the system alive (by verification, updating, review, and continual improvement).

ISO 22000:2005 emphasizes the necessity that personnel whose activities have any impact on food safety shall be aware of the relevance and importance of this fact. Therefore, the organization shall provide training or take other appropriate action to ensure personnel have the necessary competencies and awareness. It is important to mention that within the top management responsibilities, the establishment, implementation and maintenance of procedures to manage potential emergency situations and accidents that can impact food safety are also included.

Documentation forms an integral part of management systems. as it has a key role in the case of certification. ISO 22000:2005 deals with the general rules of the documentation in a separate clause, but every clause which specifies any form of documentation draws the attention to it. The Standard differentiates the following types of documents:

- Documented procedures, methods or statements. This means much more than a simple putting down in writing. This type of document shall be developed, implemented, and updated as a part of the food safety management system. Such document is, for example, the food safety policy, the procedure for handling of potentially unsafe products, or the method of hazard analysis.
- Records. The Standard requires this type of document in many cases as they provide evidence of activities performed. Records can be used to demonstrate the suitable operation and the effectiveness of the food safety management system.
- Other documents, for example product specifications.

The main advantages of ISO 22000:2005 can be summarized as follows:

- gives one set of requirements that can be applied to any organization in the food chain in any country;
- internationally recognized;
- auditable, as it contains requirements;
- flexible, organizations can choose which methods and approaches they use to fulfil the requirements of ISO 22000;
- can be applied independently of other management system standards;
- can easily be integrated with existing other management systems and/or with the HACCP method;
- allows small or less developed organizations to implement an externally developed combination of control measures; and
- supported by other ISO deliverables (ISO/TS 22002-1:2009; ISO/TS 22003:2007; ISO/TS 22004:2005; ISO 22005:2007 and *An easy-to-use checklist for small business*).

According to the data of *The ISO Survey of Certifications – 2008* during 3 years, after the publication of ISO 22000, at least 8206 organizations in 112 countries were independently certified to ISO 22000:2005 and their number continuously increases every year.

International International Technical Specification ISO/TS 22004:2005, Food Safety Management Systems – Guidance on the Application of ISO 22000:2005

This ISO document assists the adoption of ISO 22000:2005. As there was a great demand to publish the guidance close to

the date of publication of ISO 22000, it was decided to prepare it as a Technical Specification (TS). In this case, the ISO procedure is shorter; in addition, the required degree of consensus for publication is lower than in the case of an International Standard. ISO/TS 22004 was published in November 2005.

The guidance deals with those parts of the requirements of ISO 22000:2005 which should be handled with special attention. For example, it provides the small and/or less developed organizations with additional information. ISO/TS 22004 helps to avoid misinterpretation of ISO 22000 and to clarify the meanings of its terms. It provides the users with such explanations which were not possible to include in the standard but promoted its application.

International Technical Specification ISO/TS 22003:2007, Food Safety Management Systems – Requirements for Bodies Providing Audit and Certification of Food Safety Management Systems

Certification of the implemented food safety management system (FSMS) is not a requirement of ISO 22000, but – as mentioned before – it is one means of providing assurance that an organization has implemented a system for the management of food safety in line with its policy. Therefore, the number of organizations in the food chain which have certified FSMS continually increases.

ISO/TS 22003 was developed to promote decreasing quality differences among activities of the certification bodies, and giving certification only to those suppliers whose management commitment to food safety ensures that they will operate an effective FSMS.

ISO/TS 22003 was developed in harmony with ISO/IEC 17021:2006, *Conformity assessment – Requirements for bodies providing audit and certification of management systems*, which contains the general requirements for bodies providing audits and certification of management systems.

ISO/TS 22003 defines specific rules applicable for the audit and certification of a FSMS complying with the requirements given in ISO 22000:2005 (or other sets of specified FSMS requirements), and provides the necessary information and confidence to customers about the way certification of their suppliers has been granted.

International Standard ISO 22005:2007, Traceability in the Feed and Food Chain – General Principles and Basic Requirements for System Design and Implementation

The traceability of food products 'from the farm to the fork' is an important requirement of ISO 22000, therefore ISO developed a separate standard for this purpose. ISO 22005 complements the relevant Codex documents and helps food producers and manufacturers to comply with the relevant statutory requirements by providing an internationally recognized approach for designing a traceability system.

ISO 22005:2007 can be applied by an organization operating at any step in the feed and food chain. It is intended to be flexible enough to allow feed organizations and food organizations to achieve identified objectives.

The traceability system is a technical tool to assist an organization to conform to its defined objectives, and is applicable when necessary to determine the history or location of a product or its relevant components.

ISO 22000, *Food Safety Management Systems – An Easy-To-Use Checklist for Small Business – Are You Ready?*

This handbook is a joint publication of ISO and the International Trade Centre (ITC). It is built up as follows: it quotes a part from ISO 22000, and raises a question relating to the quoted part.

- If the reply is 'Yes', it says 'Go to the next question'.
- If the reply is 'No' it says 'See guidance below.'

This structure makes possible to detect each weak and missing point of an existing FSMS in an effective and rapid way, and at the same time offers suitable solution(s) for their elimination.

International Technical Specification ISO/TS 22002-1:2009, Prerequisite Programs on Food Safety – Part 1: Food Manufacturing

This is the newest member of the ISO 22000 standard family and at the same time the first member of a new series, within this family, planned to develop relevant food sectors. ISO/TS 22002-1 were published on 15 December 2009.

The new technical specification applies to all organizations involved in the manufacturing step of the food chain, regardless of size or complexity. It is not a requirement of ISO 22000 and may be used in parts or in its entirety, depending on the nature of food manufacturing operations.

Availability of International Organization for Standardization Deliverables

The hard copy of each member of ISO 22000 standard family can be ordered from ISO national member institutes, and from the ISO Store at the Central Secretariat. The whole ISO 22000 standard family is also available on a CD format (bilingual, English and French).

INSTITUTIONS INVOLVED IN FOOD SAFETY

International Life Sciences Institute (ILSI)

N van Belzen, ILSI Europe, Brussels, Belgium
E Hentges, ILSI North America, Washington, DC, USA
J Chen, ILSI Focal Point in China, Beijing, China
YB Yee, ILSI Southeast Asia Region, Singapore
S Harris, ILSI/ILSI Research Foundation, Washington, DC, USA

Glossary

Acceptable daily intake (ADI) Estimate of the amount of a substance in food or drinking water, expressed on a body weight basis, which can be ingested daily of a lifetime by humans without appreciable health risk.

As low as reasonably achievable (ALARA) A risk management approach that aims to keep exposure to a compound at the lowest level that is realistically achievable.

Exposure assessment Assessment of the amount of a particular chemical agent that reaches the target population, organism, organ, tissues, or cells, usually expressed in numerical terms of substance concentration, duration, and frequency.

Genotoxic carcinogen A compound that causes cancer by binding to DNA.

Harmonization Agreement on general principles of food safety standards as well as technical aspects, for example, methodologies, information requirements, or criteria for determining unacceptable risks, by groups representing national and international governmental bodies and others.

Hazard analysis critical control point (HACCP) A system that identifies, evaluates, and controls hazards that are significant for food safety.

Margin of exposure (MOE) The ratio between a reference concentration of a compound (often taken from an animal study and corresponding to the dose that causes a low but measurable response in animals) and the estimated dietary intake in humans.

Probabilistic modeling Use of statistical tools to estimate the likelihood of an event occurring based on historical data.

Risk analysis A discipline comprised of three components: risk assessment, risk management, and risk communication, that is used to provide food safety regulators with the information and evidence they need for effective decision-making to improve public health.

Risk assessment A process intended to calculate or estimate the risk to a given target organism, system, or (sub)population, including the identification of attendant uncertainties, following exposure to a particular agent, taking into account the inherent characteristics of the agent of concern as well as the characteristics of the specific target system.

Purpose and Structure of International Life Sciences Institute

The International Life Sciences Institute (ILSI) is a nonprofit, worldwide organization established in 1978 to advance scientific understanding of nutrition, food safety, toxicology, risk assessment, and the environment. Working through its 15 branches around the world and Research Foundation, ILSI brings together scientists from academia, industry, government, and the public sector for a balanced approach to solving problems of common interest for the health and well-being of the public. Figure 1 provides an organizational chart for ILSI.

The ILSI branches are membership organizations. Food processors, ingredient manufacturers, pharmaceutical manufacturers, agrochemical companies, and others are members of one or more branches. The ILSI Research Foundation does not have members.

All ILSI entities use a tripartite model involving scientists from academia, government, and industry to address scientific questions. ILSI entities address topics of interest through committees, task forces, or working groups made up of experts in the topic. All of ILSI's work becomes public knowledge through publications and meetings.

Each ILSI entity is governed by a group of nonindustry and industry scientists. The ILSI Board of Trustees, a 31-member international body, sets policy for the whole organization. All of the governing bodies are at least 50% nonindustry.

The branches work with their national and regional governmental bodies to ensure that these groups have access to the latest scientific information. For example, ILSI Europe aims to provide scientific information that can support the work of organizations like the European Food Safety Authority (EFSA), the Health and Consumer Protection Directorate-General of the

 doi:10.1016/B978-0-12-378612-8.00394-2

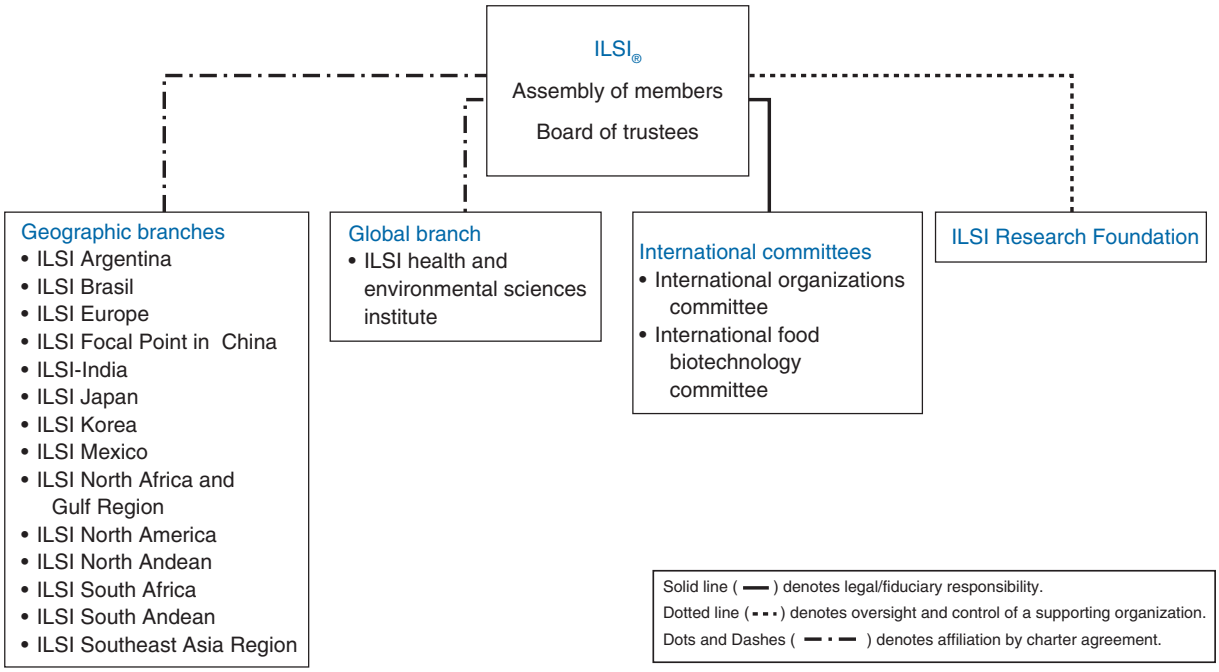

Figure 1 Organizational chart for the International Life Sciences Institute (ILSI). Reproduced from www.ilsi.org, with permission from International Life Sciences Institute.

European Commission (DG SANCO), and the national authorities in Europe. ILSI Focal Point in China provides current scientific information to the Ministry of Health on hot topics in food safety as a reference for their risk-management decisions. ILSI North America has cooperative programs with the US Food and Drug Administration, Centers for Disease Control and Prevention, Department of Agriculture, and other federal food safety agencies. ILSI Southeast Asia (SEA) Region has a long-standing working relationship with the ASEAN Health Authority on capacity building training and harmonization of safety standards. ILSI is also recognized by the World Health Organization (WHO) and the Food and Agriculture Organization of the United Nations (FAO) as a nongovernmental organization.

International Life Sciences Institute's Role in Microbial Safety

ILSI Europe has published an extensive series of monographs on different foodborne pathogens, including their occurrence, toxicity, and mitigation options; the latest edition concerns food-related viruses. Other activities include guidelines on food safety objectives and a monograph on hazard analysis critical control point (HACCP), which is currently in its third edition; the first edition was translated into seven languages.

ILSI North America Committee on Food Microbiology is committed to providing sound science to improve understanding and control of microbial food safety hazards to enable scientifically-informed decision-making. For example, 4 years before the 1993 *Escherichia coli* outbreak in Washington state, the committee recognized the potential public health threat of this emerging pathogen and began supporting research that provided critical data on the prevalence of *E. coli* 015:H7 in retail foods and the development of detection methods still being used today. Data from these research projects were critical to the rapid recognition and control of the 1993 outbreak.

In addition, ILSI North America maintains a reference strain collection, including *Listeria monocytogenes* and *Cronobacter* (*Enterobacter*) *sakazakii*, for distribution to researchers worldwide. Current research priorities include *Salmonella* in low-moisture foods, control of sporeforming bacteria, and foodborne viruses.

International Life Sciences Institute's Role in Chemical Food Safety

Increasing sensitivity of analytical equipment and its concomitant decrease in detection levels result in the identification of low amounts of undesired chemicals in food and beverages, which requires assessment of their risks. Using the Paracelsus theorem which defines chemical substance as a health concern based largely on its dose, ILSI has helped develop the threshold of toxicological concern (TTC) concept, that provides a rationale and decision tree to indicate whether a chemical of known structure and exposure is a potential health concern, or not. The TTC concept is being applied for flavorings and its application for other purposes, such as cosmetic products, is being investigated. This is one example of how ILSI has contributed to scientifically based risk assessment methodologies.

Genotoxic carcinogens, which are chemicals that cause cancer by directly binding to the DNA, are exceptions to this approach. Although from a cell and tissue biology point of view it could be argued that thresholds might exist (e.g., due to DNA repair mechanisms and cell turnover), risk assessment has traditionally assumed the absence of a threshold for these compounds. Thus, it is assumed that any exposure above zero to genotoxic carcinogens could be a concern. Therefore, levels of these compounds must be kept as low as reasonably achievable (ALARA) in food. This ALARA approach, however, does not provide guidance to assess levels of concern and priority setting. Together with WHO and EFSA, ILSI has investigated the use of the margin of exposure (MOE) concept, which determines the ratio between experimentally derived toxicity data and exposure data in humans and can be used for prioritization of risk management actions.

As a result of the data from the ILSI North America Committee on saccharin's 13-year mechanistic research program, the International Agency for Research on Cancer (IARC) downclassified it in a precedent-setting process in its monograph evaluation series in 1999, the National Toxicology Program removed saccharin from its Congressionally-Mandated List of Carcinogens (also a precedent setting event) in 2000, the Joint FAO/WHO Expert Committee on Food Additives (JECFA) increased its temporary acceptable daily intake (ADI) level, and the Canadian Government accepted a reasonable no-effect level for saccharin. Even more importantly, these data have been applied by the US Environmental Protection Agency in developing new guidelines for risk assessment that include the concept of mode of action as a key determinant of risk.

Recently, the ILSI Research Foundation has been exploring how the dose–response relationship at very low doses can be an approach in quantitative risk assessment. The concept of a threshold for adverse effects is fundamental in regulatory toxicology, underlying basic values such as ADI and tolerable daily intake. Analyzing the fundamental biological processes underlying human health effects for chemicals, allergens, pathogenic organisms, and nutrients led to a cross-disciplinary mode-of-action based analytical approach – Key Events Dose–Response Framework – that systematically examines important, required biological and chemical events along the pathway between exposure/intake and the ultimate effect of concern. The approach is described in a series of five papers published in the September 2009 issue of *Critical Reviews in Food Science and Nutrition*.

This new work provides an evidence-based approach and powerful new tool for using our growing understanding of fundamental biology and mechanistic data to reduce reliance on default assumptions, to quantify variability, and to better characterize biological thresholds.

Allergen Safety

Like many other allergens, food allergens are harmless to most people but a significant health risk to a minority, inducing a wide range of effects from mild irritation of the oral mucosa and the skin to anaphylactic shock and death. ILSI-funded research has used clinical data on eliciting allergen doses in combination with the population distribution of allergic individuals for probabilistic modeling of allergen risks. ILSI North America has reviewed a unique set of clinical challenge data for peanut allergens. A dose–response curve for risk characterization of the sensitized population was developed to validate the concept of a threshold level.

Food Safety Training and Education Activities

ILSI Europe organized a continuing education course on TTC at the meeting of European toxicological societies (Eurotox) in 2009. Training programs in collaboration with FAO and WHO to encourage the use of risk assessment in food safety control have been and are being organized in China, Southeast Asia, and Latin America. These workshops address topics such as setting of food safety standards, safety, and exposure assessment of food additives, microbial, mycotoxins, and other contaminants in the food chain. ILSI North America organized and sponsored 52 symposia, technical sessions, and workshops (1993–2009) on emerging global issues in food microbiology through its symposium series with the International Association for Food Protection.

Harmonization across Countries/Regions

Recognizing the difficulty that many countries in Central, Northern, and Southern Eastern Europe experience to harmonize their nutrition and food safety approaches with that of Western Europe, ILSI Europe provides travel grants for scientists from these countries to attend selected scientific events and courses in Western Europe.

In 2001, ILSI SEA Region collaborated with FAO–UN and WHO to establish an ASEAN (comprising 10 countries of the Association of Southeast Asian Nations) Working Group on Food Safety Standards Harmonization. Since then, a series of annual workshops have been conducted to promote scientific understanding and facilitate consensus on the application and implementation of risk analysis, exposure assessment, and harmonization of food safety standards in the region in line with Codex general standard for food additives (GSFA). A database was developed for the working group and the countries to tract the harmonization effort.

ILSI branches in China, Japan, and Korea exchange information on food safety regulations and standards, with the goal of facilitating harmonization these regulations and standards for Asian countries.

Summary Statement of What International Life Sciences Institute as an Nongovernmental Organization has been Able to Accomplish

For more than three decades, ILSI has advocated the use of science in public health decision-making. ILSI has established risk assessment and benefit assessment methodologies for evaluating diet, pharmaceuticals, and chemicals in relation to human and environmental health. Its unique mode of operation that brings together scientists from academia,

government, and industry to address food safety issues has proven effective in generating valuable scientific knowledge applicable for improving human health. The ILSI approach will continue to be relevant in the future for food safety decision-making.

For more information about ILSI and its scientific contributions, please visit the ILSI website (www.ilsi.org). The site has an advanced search function that allows the visitor to retrieve scientific publications sponsored by ILSI. The Scientific Issues section of the website has a subject-matter specific interactive risk assessment diagram that provides information on all ongoing activities in this area.

INSTITUTIONS INVOLVED IN FOOD SAFETY

FoodDrinkEurope

B Kettlitz, FoodDrinkEurope, Brussels, Belgium

Glossary

Codex Alimentarius (Latin for 'food code' or 'food book') is a collection of internationally recognized standards, codes of practice, guidelines and other recommendations relating to foods, food production, and food safety.

ETP European Technology Platform – A European network bringing together researchers, industry and, other relevant stakeholders in a particular technological field in order to foster European research and development in the concerned area.

European Rapid Alert System (RASFF) European system aiming at providing control authorities with an effective tool for the exchange of information on measures taken to ensure food safety.

FACET Flavors, Additives and Contact materials Exposure Task – European 7th Framework Project.

SMEs Small and medium enterprises – not having more than 250 employees.

Introduction to FoodDrinkEurope (formerly CIAA)

FoodDrinkEurope is the Umbrella Organization of the European Food and Drink Industry. FoodDrinkEurope membership is comprised of 26 national federations, including 3 observers; 26 EU sector associations; 18 major food and drink companies, of which the majority are Small and Medium Sized Enterprises (see Tables 1 and 2).

17 Major Companies

Agrokor, Cargill, Coca-Cola, Danone, Ferrero, General Mills, Heineken, Heinz, Kellogg, Mondelez (formerly Kraft Foods), Mars, Nestlé, PepsiCo, Südzucker, Tate & Lyle, Ülker, and Unilever.

The EU food and drink industry serves almost 500 million consumers with a wide variety of safe and high quality products.

The mission of an industry association is to represent the interests of its members. For FoodDrinkEurope, this means representing their interests at both the European and international institution levels.

FoodDrinkEurope contributes to the development of a legislative and economic framework for the food and drink industry, addressing competitiveness, food quality, and safety, consumer information and respect for the environment.

Access to safe food is an imperative for health, social, and economic reasons.

Although food in Europe is more varied and safer than ever before and the consumer is better informed and more aware of food related issues, consumers still do not appear to have sufficient trust in the supply chain.

FoodDrinkEurope Priorities

One of the key priorities of FoodDrinkEurope and its membership is therefore to increase consumer confidence in the food and drink industry.

To respond to this priority, FoodDrinkEurope is working together with more than 500 industry experts to address challenges related to food safety in the areas of process contaminants, contaminants, ingredients, food contact materials, in addition to novel foods, emerging technologies and others.

Very recently, a nanotechnology expert group was created by FoodDrinkEurope. This is a group in which both expert knowledge and communication skills are necessary to contribute to the public dialogs which are key to establishing trust in the food and drink industry.

Holistic Approach

The food and drink industry has developed an integrated and holistic approach to food safety. Safety is not guaranteed by 'safe' product manufacture – the total chain must be taken into account (see figure below):

 doi:10.1016/B978-0-12-378612-8.00009-3

- Processed meat
- Sauce & condiments
- Soft drinks
- Spices
- Sugar
- Yeast

Work with Food Chain Partners

As not all food chain partners are members of FoodDrinkEurope, a Food Safety Platform, involving consumer representatives, farmers, feed producers, traders, restaurants and retailers was created at the initiative of the FoodDrinkEurope in 2005. The Platform members strive to exchange information related to the safety of the food chain, emerging issues included.

Emerging Issues

FoodDrinkEurope aims to solve emerging issues. These may be raised by individual members, provided that these are relevant for the entire food industry. The Association also analyses the European RASFFs (Rapid Alerts which aim to provide control authorities with an effective tool for the exchange of information on measures taken to ensure food safety.) which are published on the European Commission website in this respect.

FoodDrinkEurope has put in place an 'Incident Management System', which allows the organization to serve its members immediately, or within 48 h at the latest, by means of establishing appropriate:

- Information networks,
- Links with risk managers, and
- Risk assessors

to address the issue as necessary.

The ultimate aim of the above is the protection of consumer health and the prevention of unnecessary 'scare stories', which naturally have the potential to undermine consumer confidence in the food and drink industry.

The establishment of such a system has been proven to be successful and is appreciated by its members, due to its harmonized approach towards addressing issues and seeking solutions.

Example: Dealing with Emerging Issues

FoodDrinkEurope, together with its members, is also developing tools, such as guidelines for the proper interpretation of new legislation. Examples of these are the 'GMO Guidelines' and the 'Acrylamide Toolbox', the latter of which aims to help producers to find tools to mitigate acrylamide. The Toolbox was last updated in 2011.

Given that the majority of FoodDrinkEurope members are small and medium sized enterprises (SMEs), it is important that relevant information is addressed directly to such enterprises in a clear language and in translated versions. FoodDrinkEurope has for example, provided its members with 'acrylamide pamphlets' which offer 'tools to try' for five different sectors, namely:

- Bread products,
- French fries,
- Potato crisps,
- Biscuits, and
- Breakfast cereals.

These pamphlets have been translated into 22 languages and both the Acrylamide Toolbox and the pamphlets have been recognized by risk managers. Links to the papers are available on the European Commission website.

Joint Industry Groups

Where necessary, FoodDrinkEurope also joins coalitions to address particular issues of temporary concern and seeks the expertise of other industry partners in 'joint industry groups' which are particularly relevant in areas related to the packaging and ink industry.

The role of an industry association is also of course to join research projects where these are relevant to its general work. For FoodDrinkEurope, such a research project concerns refinements of exposure assessments for flavorings, additives and food contact materials, (FACET stands for Flavors, Additives and Contact materials Exposure Task) for instance.

Research and Innovation

Project involvement is of course insufficient to address elements to further improve food safety. The European Technology Platform 'Food for Life' was therefore created in 2005 under the auspices of FoodDrinkEurope. This Platform seeks to deliver innovative, novel, and improved food products for and to national, regional, and global markets in line with consumer needs and expectations.

This Platform offers the unique opportunity to merge academic knowledge with industry needs and, by doing so, to improve the integration of research investments and thereby facilitate competitiveness and wealth creation. Innovation and effective technology transfer will stimulate economic growth.

Stakeholders have been involved in the shaping of a Strategic Research Agenda which also addresses:

- The building of consumer trust in the food chain,
- The support of sustainable and ethical production, and
- The improvement of health, wellbeing, and longevity.

Regulation and Self-Regulation

It is the role of an industry association to react to questions which are integrated within regulatory processes and to proactively address questions which do not yet feature on the radar-screen of policymakers. An industry association will offer assistance in both developing self-regulatory measures or, if necessary, intervene in regulatory processes in order to address industry-specific issues.

Involvement in Global Tasks

In addition to acting at European levels, it is necessary to reach out to global players and therefore to actively contribute to developments within Codex Alimentarius.

In this respect, FoodDrinkEurope also addresses trade-related questions and avails of its networks in order to solve eventual issues either internationally, where new legislation has been introduced, or at European level, where the internal market is at risk of being disturbed due to the incoherent implementation of European legislation.

INSTITUTIONS INVOLVED IN FOOD SAFETY

International Food Information Council (IFIC) and Other Food Information Organizations

DB Schmidt and AP Benson, International Food Information Council and Foundation, Washington, DC, USA

Glossary

Dietary Guidelines Alliance A private-public partnership among leading food, nutrition and health organizations and societies, food industry organizations and the government, dedicated to providing consumers with science-based, practical advice on how to apply the Dietary Guidelines for Americans to their lives.

Food processor A person, facility, company or machine that transforms raw ingredients into food, or that transforms food into other forms for consumption.

Food safety Assurance that food will not cause harm to the consumer when it is prepared and eaten according to its intended use.

Nutrition The science of how the body uses food.

Risk communication The interactive exchange of information and opinions throughout the risk analysis process concerning risk, risk-related factors and risk perceptions, among risk assessors, risk managers, consumers, industry, the academic community and other interested parties, including the explanation of risk assessment findings and the basis of risk management decisions.

Introduction

Founded in 1985, the International Food Information Council (IFIC) is a nonprofit organization, whose mission is to effectively communicate science-based information about food safety, nutrition and health to health and nutrition professionals, educators, government officials, journalists and others providing information to consumers. Based in Washington, DC, IFIC is supported primarily by the broad-based food, beverage and agricultural industries. The organization does not represent any product or company, nor does it lobby for legislative or regulatory action.

The IFIC Foundation was incorporated as a public education foundation in 1991 and serves as the educational arm of IFIC. The IFIC Foundation is guided by a Board of Trustees, the majority of whom represent public institutions such as universities, governmental bodies, and public foundations.

IFIC participates in, and helps to facilitate cooperation and exchange between the members of an informal network of independent food information organizations in Asia, Europe, New Zealand and South Africa and South America.

Why Do we Need Food Information Organizations?

The food supply chain relies on a complex system involving farmers, growers, ingredient suppliers, food processors, food distributors, food importers, food regulators, and food retailers in many different world regions.

Modern media outlets can transmit news about food safety developments or crises across the world in microseconds. So a crisis in one part of the world has the potential to alarm consumers across the globe.

Technological advances and other new practices in sanitation and detection methods can help reduce potential food safety risks. Yet the task of providing the public with accurate and understandable information to explain these developments remains a daunting one, and it is here that food information organizations play a critically important role.

If the food chain does not function with effective communications among key parties, a potentially disastrous food incident can still result. That is why we need food information organizations, and why their collective reach needs to be local, regional and global.

The Fundamental Underpinnings of Food Safety

Though food safety challenges can be complex, it could be argued that just three key elements constitute the fundamental underpinnings of food safety.

First and foremost is sound science that includes good agricultural and food safety practices, and which has to be a prerequisite. But where science is complex and where the food chain is long, an appropriate level of oversight is clearly necessary.

So the second key element has to be an appropriate level of food safety regulation, together with an adequate measure of regulatory oversight and inspection.

But what happens if key information regarding even basic food hygiene doesn't reach a grower in a developing country, or a food server in a Western quick service outlet? This is the

third key element that underpins food safety, namely effective communications to and from key stakeholders along the length of the food chain.

The IFIC's Food Safety Role

IFIC and its Foundation aim to bridge the gap between science and communications by collecting and disseminating scientific information in a manner consumers can understand, and by working with an extensive roster of experts to help translate research into understandable and useful information and advice for stakeholders, journalists and other opinion leaders and consumers.

In times of a food safety emergency, IFIC plays a key role, briefing the media and informing the public, partner organizations and key stakeholders about important developments that could impact public health and well-being. IFIC serves as a news media resource, and can refer journalists to over 350 independent, credentialed experts on a variety of nutrition and food safety topics.

The Need for International Cooperation

Given the international nature of today's food supply, IFIC recognizes that it is important to disseminate and exchange key information and advice on nutrition and food safety globally.

IFIC participates in and helps to facilitate cooperation and exchange between an informal, global network of independent food information organizations.

Working independently but exchanging knowledge and insight internationally, these organizations all share a common goal of bringing science-based insight and understanding to regional and international food safety and nutrition issues.

Informed decision making by policy makers, stakeholders and consumers helps to maximize levels of food safety, and helps to minimize the consequences of any food safety incident. Informed decision also helps to avoid misinformation and confusion, reducing the risk and the consequences of unfounded public alarm.

Clear and consistent communications – that engage health and nutrition professionals, educators, government officials, opinion leaders and the media – help build broad-based understanding that serves the shared interests of stakeholders and consumers most effectively.

IFIC Collaborations

IFIC has established partnership programs with a wide range of credible professional organizations, government agencies and academic institutions, including a long-standing relationship with the U.S. Department of Agriculture and Food and Drug Administration as part of the Dietary Guidelines Alliance and the *MyPyramid* Food Guidance system, as well as food safety education materials for consumers.

IFIC hosts or participates in major national and international professional conferences and meetings including programs organized by the World Health Organization, the Food and Agriculture Organization of the United Nations, the International Congress of Nutrition and other key international authorities and expert groups.

The IFIC Foundation also participates in a recently formed International Center of Excellence in Food Risk Communication (http://foodriskcommunications.org). The Center is collaborative initiative among global food and health organizations, government agencies, academic institutions, and expert nonprofit communication organizations, founded on the belief that it is important to have a collective international resource of food-specific risk communication materials which are dedicated to enabling informed decision-making to promote global health.

IFIC has helped to develop a number of key training resources for food safety risk communication including *Improving Public Understanding: Guidelines for Communicating Emerging Science on Nutrition, Food Safety and Health* (based on an advisory group convened with Harvard School of Public Health), *A Practical Guide to Risk Communication* (a Continuing Professional Education Module self-study unit developed with the University of Maryland) and *Risk Communicator Training for Food Defense Preparedness, Response and Recovery* (developed through the National Center for Food Protection and Defense).

These and other key resources can be accessed on the IFIC Foundation Web site at www.FoodInsight.org. The IFIC Foundation uses the latest technology, communication tools and interactive formats, including a Blog, a *FoodInsightTV* channel, Web casts, educational videos, a Facebook page and a Twitter account. The popular monthly *Food Insight* newsletter (available online only) helps stakeholders stay on top of the latest research and trends.

IFIC and its Foundation commission primary research on public opinion about food safety and nutrition and shares the results with stakeholders and the public. The *Food & Health Survey* provides information about how Americans connect the food they eat with their health. Recent surveys have explored topics such as food safety, overall diet, physical activity, weight management, dietary fats, functional foods, caffeine, and food allergies.

IFIC (www.ific.us) and the IFIC Foundation (www.foodinsight.org) are headquartered at: 1100 Connecticut Ave, NW, Suite 430; Washington, DC 20036. Tel.: +1 202/296-6540; Fax: +1 202/296-6547.

How Do International Food Information Organizations Cooperate?

The international food information organizations operate autonomously and independently yet they share insight, consumer attitudinal research and best practices in risk communication globally.

The food information organizations realize that, although knowledge and expertise should be shared internationally, communications need to be handled regionally and locally to have the desired impact and effectiveness.

Effective communication organizations need to have the linguistic capabilities to reach stakeholders and consumers in

their regions. But beyond language there are the key questions of credibility and impact.

Who are the trusted authorities in the region? What are the most effective communication channels? What are the regional sensitivities regarding particular food and nutrition issues, and what sort of messaging is needed to communicate accurately, clearly and effectively?

The food information organizations determine locally who have detailed first-hand knowledge of the issues, communications challenges and cultural sensitivities in the region.

So Who are Other Key International Food Information Organizations?

The Asian Food Information Centre (AFIC) was founded in 1998 and registered in Singapore. The AFIC team of scientific, health and communications professionals works in close collaboration with the academic and scientific communities in the region.

AFIC produces and distributes a wide range of science-based, consumer-friendly information on food safety and nutrition through workshops, interviews, articles, information leaflets and multilanguage website. AFIC publications include the *Food Facts Asia* newsletter and an *AFICNews* E-bulletin.

AFIC also conducts research into consumer behavior, perceptions and expectations.

Mailing Address: Shaw Centre #23-14, 1 Scott's Road, 228208 Singapore. Tel.: +(65) 6235 3854; Fax: +(65) 6235 7459. E-mail: info@afic.org. Website: www.afic.org.

The Council for Food Safety and Nutrition Information (CISAN) was newly formed in 2010 and has its operational base in Buenos Aires, Argentina. Its mission is to share science-based information on food safety, nutrition and health with health professionals, communicators and consumers, so as to enhance understanding and enable informed food choices. CISAN is operated as a collaborative initiative between three prestigious institutions, namely the Argentine Nutrition Foundation, the International Life Science Institute of Argentina, and the Argentine Council for Information on Biotechnology.

CISAN's website can be accessed at http://cisan.org.ar. To contact CISAN, please send an E-mail to info@cisan.org.ar.

The European Food Information Council (EUFIC) is a nonprofit organization, which provides science-based information on food safety and quality, and health and nutrition to the media, health and nutrition professionals, educators and opinion leaders, in a way that consumers can understand.

EUFIC's mission is to enhance the public's understanding of such issues and to raise consumers' awareness of the active role they play in safe food handling and choosing a well-balanced and healthy diet.

Information that EUFIC publishes has been subject to a review process by members of its Scientific Advisory Board (SAB). Given the broad range of subjects addressed in EUFIC's popular newsletter, *Food Today*, a dedicated Editorial Board for this publication provides additional insights and feedback.

With its main offices located in Brussels (Belgium), EUFIC counts on and liaises with a European network to enhance the impact and outreach of its communication instruments and programs in other countries.

EUFIC actively participates in European initiatives together with the European Commission Directorate Generals for Research, and for Health and Consumers, where it contributes to a number of projects as dissemination partner.

EUFIC's website is www.eufic.org. To contact EUFIC, please send an E-mail to eufic@eufic.org.

The Food Advisory Consumer Service (FACS) is South Africa's first independent food and nutrition consumer service. First launched in January 1995, its purpose is to provide consumers with information on food and nutrition issues which is both relevant and scientifically correct.

FACS operates a telephone information service, supported by a network of technical experts in food, nutrition and related subjects.

FACS is run by a committee representing SAAFoST, the South African National Consumer Union (SANCU), the Association of Dietetics (ADSA), the Directorate of Food Control of the Department of Health, and professional representatives of other consumer-friendly organizations. FACS has access to information from similar bodies overseas. However, it is committed to offering a comprehensive service in line with South Africa's unique situation. This would include risk groups such as infants, sufferers of malnutrition and others.

FACS has good contact with the media and is a member of the Food Legislation Advisory Group, the body concerned with food legislation in South Africa, and with Codex Alimentarius, the Joint FAO/WHO Food Standards Program.

Website: http://www.foodfacts.org.za/. Postal Address: PO Box 27852, Sunnyside, 0132. Customer Hotline: 012 428 7122 (hotline available from 08:00 to 12:00); Fax: 086 672 8585.

The New Zealand Nutrition Foundation (NZNF) is a professional, nonprofit organization whose members believe all New Zealanders should have access to accurate information to enable them to make informed choices about food and the effect it has on their health. NZNF helps New Zealanders make these choices by providing a balanced viewpoint on important issues around food, nutrition and health.

Founded in 1980, the NZNF was established as a charitable not-for-profit trust, with individual and corporate membership to support its activities. The Foundation's membership includes those working in health, nutrition, education and the food industry, providing the opportunity to co-ordinate and support work between professional groups, food producers and marketers and government agencies.

Adhering body A representative body of the International Union of Food Science and Technology (IUFoST) from each country, or defined geographical area(s), that has an independent science budget.

What is IUFoST?

The International Union of Food Science and Technology (IUFoST) is the sole global, country member organization that represents more than 200 000 food scientists and technologists (Buckle and Meech, 2003). It is a voluntary, nonprofit association that links the world's food scientists and technologists through international cooperation and exchange of scientific and technical information. IUFoST is a full member of the International Council for Science and works closely with several United Nations agencies such as the Food and Agriculture Organization (FAO), World Health Organization (WHO), Codex Alimentarius Commission, and International Atomic Energy Agency as well as other international organizations to transfer technical knowledge and strategies for basic and applied research for the developing world.

IUFoST sponsors international and regional congresses, conferences, symposia, and workshops that are held in member countries, and promotes a safe, secure, and wholesome food supply for the world's increasing population.

Origin

The profession of food science and technology is generally agreed to have emerged in the USA in the early decades of the twentieth century. The subsequent formation of the (US) Institute of Food Technologists (IFT) in 1939 and its successful development and expansion led to the formation of similar associations in many countries during the following 20 years. In 1960, the UK government and several British scientific societies hosted a conference in London to commemorate the centenary of the UK Food and Drugs Act (1860) and the hundred and fiftieth anniversary of the publication in 1810 of Nicolas Appert's book (*L'art de Conserver, Pendant Plusieurs Années, Toutes les Substances Animals et Végétales*) on heat preservation of foods in sealed containers. In the preceding week, the Glasgow Royal College of Science and Technology (later to become the University of Strathclyde) convened a symposium on recent advances in food science, and discussions between several eminent UK and US food scientists raised the concept of an international food society. The formation of an international organization was discussed at the First International Congress of Food Science and Technology held in London in 1962 and organized by the Food Group of the (UK) Society of Chemical Industry.

Following the Congress, an ad hoc International Committee of Food Science and Technology (ICFoST) was formed with eminent scientists from several countries to promote and foster international cooperation in food science and technology. The Second International Congress of Food Science and Technology was held in Warsaw, Poland, in 1966. By the time the Third International Congress of Food Science and Technology (Science of Survival: SOS/70) was held in Washington, DC, USA, in 1970, ICFoST had developed a constitution and working arrangements for an international union (IUFoST), which was inaugurated on 14 August 1970.

Membership

The founding membership consisted of 20 food science and technology organizations from 20 nations; current membership includes organizations from 69 countries (http://www.iufost.org/adhering-bodies). Under the constitution, membership is open to all countries and consists of one representative body, termed as an 'Adhering Body,' from each country. The term 'country' is understood to be a defined geographical area, or areas, that has an independent science budget. Only one Adhering Body can represent each such area. Adhering Bodies can be a national food science and/or technology group, society or institute composed of food scientists, and food technologists or other professionals engaged in food science and technology; an academy of sciences, national research council, or similar organization of scientists; an intersociety committee or similar group representing two or more

Table 1 IUFoST World Congresses of Food Science and Technology

Congress no.	*Year*	*Location*
1	1962	London, UK
2	1966	Warsaw, Poland
3	1970	Washington, DC, USA
4	1974	Madrid, Spain
5	1978	Kyoto, Japan
6	1983	Dublin, Ireland
7	1987	Singapore
8	1991	Toronto, Canada
9	1995	Budapest, Hungary
10	1999	Sydney, Australia
11	2001	Seoul, South Korea
12	2003	Chicago, IL, USA
13	2006	Nantes, France
14	2008	Shanghai, PR China
15	2010	Cape Town, South Africa
16	2012	Iguazu Falls, Brazil

societies composed of food scientists and technologists; or a national committee representing food scientists, engineers, and technologists working in the field.

Mission and Activities

The IUFoST mission is to promote international cooperation and information exchange, to provide education and training to food scientists and technologists around the world, and to promote professionalism and professional organization among food scientists and technologists.

IUFoST conducts a wide range of activities in order to achieve its objectives of fostering international cooperation and exchange of knowledge and ideas. They are conducted in conjunction with the Adhering Bodies and regional groupings, or with other local, national, and international organizations.

Congresses

From 1962 to 1999, World Congresses of Food Science and Technology were conducted about every 4 years, in conjunction with the Adhering Body of that country. From 2001, they have been held biennially, commencing with the 11th World Congress of Food Science and Technology in Seoul, South Korea (Table 1).

Regional Meetings

IUFoST has been associated with more than 200 conferences, symposia, seminars, workshops, training programs, and short courses since its inception in 1970, covering diverse topics in areas such as food science, technology, engineering, and microbiology; human nutrition; national and international food law; food toxicology; product development; food security; and, in more recent years, especially food safety.

IUFoST Involvement in Food Safety Activities

Committees and Panels

The first formal committee with a brief on some aspects of food safety was set up in 1980 as the Committee on Food Composition and Food Safety, initially chaired by Dr Richard Hall (USA), who was later to become the fourth IUFoST President (1983–87). One of the first food safety activities was the First Asian Conference on Food Safety: The challenges of the 1990s, held in Kuala Lumpur, Malaysia on 2–7 September 1990, organized by the Malaysian Institute of Food Technology, International Life Sciences Institute (ILSI), Malaysian Agricultural Research and Development Institute, Malaysian Ministry of Health, and the WHO in conjunction with the Federation of Institutes of Food Science and Technology in Association of South-East Asian Nations (ASEAN) (FIFSTA)…, FAO, ILSI Australia, and IUFoST.

In 2009, IUFoST established a Food Safety Committee in response to the expressed needs of its Adhering Bodies worldwide, with the objective to advise and act within IUFoST, via the Scientific Council, on emerging and current issues in areas of food safety from the national and regional perspective, in conjunction with IUFoST Expert Panels. The Food Safety Committee consists of representatives from Adhering Bodies, including Regional Groups, together with Academy Fellows, and others. The Expert Panel members are drawn from Fellows of the International Academy of Food Science and Technology (IAFoST), from the Union's worldwide members, and from IUFoST's global partners in Europe, FAO, WHO, ILSI, International Commission on Microbiological Specifications for Foods (ICMSF), and others. The Food Safety Expert Panel advises on aspects of chemical and microbiological food safety, allergies, zoonoses, traceability and food safety policy, and regulation and reports to the Scientific Council.

Declarations on Food Security

IUFoST has long recognized the role of food science and technology in improving food security, including food safety, in the developing world, especially in Africa, Southeast Asia, and Eastern Europe. The Victoria Falls Declaration, supporting the plight of consumers in the developing world, especially in sub-Saharan Africa, was approved by delegates at the IUFoST/Eastern, Central and Southern African Association of Food Science and Technology (ECSAAFoST) joint meeting in 1994, the first International food conference held in Zimbabwe in September 1994. The declaration was based on the original declaration from the FAO/WHO International Conference on Nutrition held in Rome, Italy in December 1992, which was endorsed by 159 states and the European Economic Community.

The following year, the 9th World Congress of Food Science and Technology, held in Budapest, Hungary in July–August 1995, the Budapest Declaration, based on the FAO/WHO and Victoria Falls Declarations, was approved by delegates to the IUFoST General Assembly (http://iufost.org/budapest-declaration). Clause 1 states that IUFoST delegates will "… recognise that access to nutritionally adequate and safe food is the right of each individual…", whereas clause 7 states that IUFoST

identifies "… the following areas as being especially significant: promotion of the safety and quality of all foods…".

Delegates to the General Assembly at the 15th World Congress of Food Science and Technology held in Cape Town, in August 2010 approved the Cape Town Declaration (http://iufost.org/cape-town-declaration), which again reaffirmed IUFoST's commitment to food safety as reflected by the appearance of terms such as 'nutritionally adequate and safe food.' 'safe and wholesome foods,' 'promotion of the safety and quality of all foods,' and 'to ensure food safety.'

Publications

Trends in Food Science and Technology

Published by Elsevier, this publication is the official journal of IUFoST and the European Federation of Food Science and Technology (EFFoST), one of IUFoST's regional groupings. It is an international peer-reviewed journal publishing critical reviews and viewpoints of current technology, food science, and human nutrition.

Newsline

The IUFoST newsletter, first published in 1970, became *Newsline* with the 25th edition in March 1993, when it was first published as part of *Lebensmittel-Wissenschaft und Technologie* (*Food Science and Technology*), the official journal of the Swiss Society of Food Science and Technology and published by Elsevier Science. *Newsline* is now published electronically three times per year and is available on the IUFoST website (www.iufost.org/iufost-newsline). *Newsline* has published many articles on food safety issues, especially from IUFoST-cosponsored seminars/symposia conducted in conjunction with national Adhering Bodies.

The World of Food Science

In 2000, IUFoST and IFT, the US Adhering Body, jointly launched the online electronic magazine *The World of Food Science*, directed at food scientists and technologists worldwide. It was relaunched in October 2006, following the 13th World Congress of Food Science and Technology, in Nantes, France. Volume 3 (February 2008) features articles on food safety (http://www.worldfoodscience.org/cms/?pid=1004439). The Editorial Advisory Board includes members drawn from IUFoST's Adhering Bodies.

Scientific Information Bulletins

IUFoST's Scientific Council has produced several Scientific Information Bulletins (SIBs) on topical issues, including the following on aspects of food safety (http://iufost.org/iufost-scientific-information-bulletins-sib):

- Bovine spongiform encephalopathy (February 2004).
- Safety, risk, and the precautionary principle (August 2007).
- Best practices in risk and crisis communication: Advice for food scientists and technologists (October 2007).
- Equivalence in food safety management (December 2007).
- Chemical hazards in food (October 2008).
- Food allergy (March 2009).
- Trans fatty acids (updated February 2010).
- Biotechnology and food (updated March 2010).
- Acrylamide in foods (updated July 2010).
- Nanotechnology and food (updated August 2010).
- Chemical hazards in food (January 2011).
- Radioactive fallout from the 2011 Japan nuclear plant accident and some recommended precautions and countermeasures (May 2011).
- Shiga toxin producing *Escherichia coli*: Germany 2011 *E. coli* 0104:H4 outbreak linked to sprouted seeds.
- Food traceability (March 2012).

SIBs are prepared by members of the Scientific Council or by selected experts from around the globe.

Conferences, Symposia, and Seminars

IUFoST has collaborated with a variety of Adhering Bodies, and both national and international organizations, to provide a forum for discussions on aspects of food safety. Some examples of such activities over the past 5 years include:

- 15th IUFoST World Congress of Food Science and Technology, Cape Town, South Africa, August 2010, featuring sessions on food safety, risk assessment and contaminants, and food allergens.
- International Forum on Food Safety, Beijing, China, 2010 and 2011, with Chinese Institute of Food Science and Technology.
- IUFoST – Japan Food Safety Symposium, September 2009.
- 14th IUFoST World Congress of Food Science and Technology, Shanghai, China, October 2008, featuring technical sessions on food safety of children's foods; modern food safety control systems; food safety forum; food safety monitoring technology; food safety regulations and standards; hazard assessment and foodborne disease; hot topics in safety of food systems; food genetic engineering and food safety; and biotechnology and food safety.
- IUFoST/Food Ingredients Asia/China Conference on Natural and Safe Food Ingredients, Shanghai, China, March 2007.
- 13th IUFoST World Congress of Food Science and Technology, Nantes, France, September 2006, featuring 10 chapters on food safety in the resultant book entitled *Global Issues in Food Science and Technology* (Barbosa-Canovas *et al.*, 2009).

In addition to the above, IUFoST has collaborated with a number of national, regional, and international organizations, including:

- ICMSF,
- WHO,
- International Union of Nutritional Sciences and
- IUFoST Regional Groupings, including:
  - La Asociación Latinoamericana y del Caribe de Ciencia y Tecnologia de Alimentos (Latin American and Caribbean Association of Food Science and Technology),

- EFFoST,
- FIFSTA, and
- West African Association of Food Science and Technology.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Trust in Animals and Food Safety (TAFS) Forum

U Sperling, TAFS Forum, Bern, Switzerland

The international forum TAFS (Trust in Animals and Food Safety) is a nonprofit making Swiss foundation founded in 2002 in a response to the urgent need to enhance the communication between scientists and stakeholders of the food chain, food industry, and consumers in relation to the bovine spongiform encephalopathy (BSE) and other transmissible spongiform encephalopathy (TSE) diseases. With improvements in the prevention of BSE, TAFS extended its scope to other transmissible animal diseases such as paratuberculosis and influenza, and aspects of livestock rearing that are of relevance for food safety in general.

TAFS aims to contribute toward global food safety by acting as platform for communication on risks of animal diseases and measures for their management, particularly where important aspects of the scientific basis of animal diseases are still unclear. This is done by:

- monitoring scientific developments and provision of stakeholders with early warning and advanced information on the new scientific findings;
- interpretation of the significance of the scientific findings and possible implications on the regulatory development;
- voicing TAFS' opinion on the safety of animal-derived food and food products;
- making recommendations on voluntary risk management measures for the stakeholders;
- advocacy for regulatory measures;
- identification of gaps in science and possible areas for research.

Recommendations for risk management are nonbinding even for members and are meant as a guideline. Implementation may require adaptation to local requirements and possibilities.

The guiding principles of TAFS are: Personal trust and confidentiality, independence and impartiality, a strong commitment to a science- and fact-based approach, acknowledgment of knowledge gaps and their impact on risk management.

Communication of TAFS occurs through various channels, including international conferences, position papers, and a news stream. TAFS has so far published a number of position papers and suggested risk management plans, particularly on BSE and paratuberculosis. They are available at www.tafsforum.org for download.

TAFS has 21 members (status January 2012) from Europe, North America, and Asia, representing the food industry, regulators, and academia. Consumer views and interests are covered by social scientists. TAFS is generally open to admit new members, provided they commit to the guiding principles and actively contribute to the achievement of TAFS' goals.

INSTITUTIONS INVOLVED IN FOOD SAFETY

Global Harmonization Initiative (GHI)

H Lelieveld, Global Harmonization Initiative (GHI), Vienna, Austria

Glossary

Food safety Preventing harm from eating food.
Food security Certainty that there is sufficient food.
Global scientific consensus Consensus between scientists (including nutritionists, technologists, and engineers) from all countries of the world.
Harmonized regulations Regulations that are the same and have the same meaning everywhere.
Nutrient security Certainty that there are enough of all essential nutrients.
Sound science Knowledge based on facts that have been accepted by peers and can withstand scrutiny.
Toxic concentration Concentration of a substance in food that upon ingestion causes bodily harm.

Introduction

The Global Harmonization Initiative (GHI) is a global association of individual food scientists (in a wide sense, hence including technologists, nutritionists, and others) with a goal to "Achieving consensus on the science of food regulations and legislation to ensure the global availability of safe and wholesome food products for all consumers." Consensus statements will provide tools for stakeholders to exert pressure on legislators to make them base regulations on sound scientific evidence. Harmonized regulations will reduce the need for destroying safe food for pure differences between regulations. It will also facilitate trade between countries and the acceptance of new products or production methods once proven safe, avoiding testing in many countries with different protocols.

Although the globalization of world trade has created new pathways to economic growth for many nations, the trend toward a 'one-world economy' has also exposed critical differences in international laws and regulations that are designed to protect the world's citizens. Nowhere is this more evident than in the global food supply chain. Gaps in the science used to justify international regulations create confusion for food producers trying to achieve compliance. The result is a world of barriers to achieve food security and effective food safety – and the technological advancements that could ensure both. The need to harmonize global food regulations and laws has never been greater, considering the following challenges.

Food Security and Nutrition

Although the world as a whole produces enough food for everyone, approximately half of the food produced does not reach those who need it. As a consequence, today approximately 'one billion people' suffer from hunger. One of the major reasons is that a significant percentage of the food is destroyed during harvesting, transport, and storage. Much is spoiled before consumption owing to inadequate preservation, but food may also be deemed unfit for consumption – and consequently destroyed unnecessarily – without scientific justification due to laws that have been developed arbitrarily and are not founded on sanitary or other technical (e.g., rights of consumers and fair trade) reasons. In addition, food preserved to prevent microbial spoilage often has a significantly reduced concentration of essential nutrients. This can significantly be remediated by novel technologies, if their applications are not hindered by scientifically unjustified differences in regulations between nations.

Food Safety

Nations enact food safety regulations to protect consumers from foodborne illness. This is needed because some unscrupulous producers and tradesmen are more concerned about making a profit than safeguarding consumer health. Regrettably, significant differences in food safety regulations between nations can, and do, result in situations in which a food that is considered safe in one country is considered unfit for consumption in another country. This, in turn, leads to the destruction of imported foods that are safe but that do not meet regulatory requirements, or prevents countries from exporting food to areas where it is needed. Without globally harmonized, science-based regulations, rules intended to protect consumers from foodborne illness or death merely serve to erect trade barriers that inhibit technologic advancements that ensure public health.

 doi:10.1016/B978-0-12-378612-8.00440-6

Technology and Method Development

New technologies and scientific methodologies may have drawbacks, so there must be proof that such technologies offering beneficial solutions for one problem will not jeopardize other safety aspects. Thus, there is a fair and logical requirement to prove that food produced using a new process is still safe. Defining what constitutes a 'safe' process for ensuring food safety is challenging when the laws and regulations of countries differ, because validation must occur in many countries following different protocols, resulting in significant hurdles to new technology application.

For example, to protect crops against insects and other pests, producers use traditional prevention methods. Clearly, traditional methods work but they do have drawbacks, such as potentially toxic residues, destruction of nutrients, and dramatic losses to crushing or foraging animals. All over the world, scientists and engineers are developing methods that minimize, or even eliminate, such drawbacks. Results include more insect-resistant crop varieties and packaging that effectively protects against mechanical damage and pest infestation. Similarly, to prevent microorganisms from adulterating food preservation methods are developed that need neither heat nor chemicals to stop microbes from doing harm and help retain more of the food's essential nutrients. However, without agreement between countries about the validity of these technologic approaches, neither food producers nor consumers will benefit from the increased food safety and nutritional benefits they can provide.

Testing protocols used to establish the safety of the food itself or validate a preservation process' safety also require harmonization. A case in point is the prescribed testing protocols involving the use of animals, which not only poses serious ethical objections but, for processed food to cross borders, meeting legal requirements can be difficult, costly, and time-consuming. There is increasing evidence that the results of animal testing to determine toxicity of foods, cosmetics, and pharmaceuticals have little or no relevance to humans or human health outcomes. In fact, easy-to-apply alternative methods have been developed. Although these animal-free methods have been shown to return a faster, more accurate speed-to-result, expected financial benefits of their use cannot be realized if the protocols for product safety testing are not globally harmonized.

Historical Background

In view of the above, in 2004, members of the International Division of the Institute of Food Technologists (IFT) and representatives of the European Federation of Food Science and Technology (EFFoST), which is the European branch of the International Union of Food Science and Technology (IUFoST), were motivated to contribute to the harmonization of food safety regulations, globally. This resulted in the formation of the GHI in 2007. Shortly after establishing GHI, many scientific organizations joined the effort, which now boasts a growing, truly global membership dedicated to achieving consensus on the science of food regulations and legislation to ensure the global availability of safe and wholesome food products for all consumers.

Modus Operandi and Activities

From its inception, GHI's strategy has been to provide a networking forum in which food scientists could practice science. Its goal is to foster global scientific consensuses on issues for which globally equal regulations will help strengthen global food safety and alleviate global hunger and nutrition problems. By producing independent, authoritative information based on scientific consensus, GHI hopes to inform the world's regulators and lawmakers so that regulations are based on sound science and not reactionary conclusions after food safety failures. Stakeholders may use GHI's objective consensus documents to provide evidence to their governments that harmonization of food regulations is possible and in their interest.

Finances and Membership

As is explicit in the constitution of the organizations, to protect its impartiality, GHI will not accept funding from industries or governments. Funding is accepted only from scientifically independent organizations. GHI's intention is to involve scientists from all countries and, to achieve this, there is no membership fee. Applicants for membership, however, need to qualify and therefore are required to provide details showing that they are food scientists and experts have to provide evidence of their expertise before being invited to judge concepts of consensus documents.

Awareness

To make colleagues aware of the initiative, GHI has held workshops, courses, and meetings in many countries, which led to the formation of working groups (WGs), focusing on a variety of topics, including *Listeria monocytogenes* in ready-to-eat food, nanotechnology application, high-pressure sterilization, and the toxicity of food ingredients. Each WG's task is to develop a concept document for discussion by experts worldwide, followed by global distribution to food scientists, technologists, and engineers, with the goal of reaching a significant global consensus on the science involved in the specific area of interest.

From the start there has been abundant publicity about GHI. Many articles can be downloaded from the GHI website. In 2010, Elsevier published the book 'Ensuring Global Food Safety – Exploring Global Harmonization,' edited and written by GHI Members from all over the world. GHI has a quarterly newsletter, which can be downloaded from the website. The newsletters are announced in many professional magazines and in emails to the membership.

Structure

The Association has an Executive Committee consisting of at least six members, namely, the president, a general secretary, a

treasurer, and members at large. There is a Supervisory Board with the task to watch that the organization remains impartial at all times. The consensus processes take place in WGs and opinions are sought from members from all countries. To maximize the input of scientists from all over the world, GHI has Ambassadors in many countries, so that issues can be discussed in local languages.

Abbreviation of Selected Organizations Involved in Food Safety

This is a nonexhaustive list of some of the frequently mentioned abbreviation in the Encyclopedia of Food Safety.

CAC	Codex Alimentarius Commission.
CDC	Centers for Disease Control and Prevention (USA).
CI	Consumers International.
EFSA	European Food Safety Authority.
EHEDGE	European Hygienic Engineering and Design Group.
EPA	Environmental Protection Agency (USA).
EC	European Commission (European Union).
FAO	Food and Agricultural Organization of the United Nations.
FDA	Food and Drug Administration (USA).
IARC	International Agency for Research on Cancer.
ICMSF	International Commission on Microbiological Specifications for Foods.
IFIC	The International Food Information Council.
ILSI	International Life Sciences Institute.
ISO	International Organization for Standardization.
IUFoST	International Union of Food Science and Technology.
JECFA	Joint FAO/WHO Expert Committee on Food Additives.
JEMRA	Joint FAO/WHO Expert Meetings on Microbiological Risk Assessment.
JMPR	Joint FAO/WHO Meetings on Pesticide Residues.
OIE	World Organization for Animal Health.
PAHO	Pan American Health Organization.
RASFF	Rapid Alert System for Food and Feed.
UNEP	United Nations Environment Programme.
USDA	United States Department of Agriculture.
WHO	World Health Organization.
WTO	World Trade Organization.

Index

Notes
Cross-references terms in *italics* are general cross-references, or refer to subentry terms within the main entry (the main entry is not repeated to save space). Readers are also advised to refer to the end of each article for additional cross-references – not all of these cross-references have been included in the index cross-references.

The index is arranged in set-put style with a maximum of four levels of heading. Major discussion of a subject is indicated by bold page numbers. Page numbers suffixed by *T* and *F* refer to Tables and Figures respectively. *vs.* indicates a comparison.

Where index subentries and sub-subentries pertaining to a subject have the same page number, they have been listed to indicate the comprehensives of the text.
